Dr WILLIS's Practice of Physick,

Being the whole

WORKS

OF THAT

RENOWNED and FAMOUS

PHYSICIAN:

CONTAINING

These Eleven Several Treatises, *viz.*

I. Of Fermentation.
II. Of Feavers.
III. Of Urines.
IV. Of the Accension of the Blood.
V. Of Musculary Motion.
VI. Of the Anatomy of the Brain.
VII. Of the Description and Use of the Nerves.
VIII. Of Convulsive Diseases.
IX. Pharmaceutice Rationalis, the First and Second Part.
X. Of the Scurvy.
XI. Two Discourses concerning the Soul of Brutes.

Wherein most of the Diseases belonging to the Body of Man are Treated of, with excellent Methods and Receipts for the Cure of the same.

Fitted to the meanest Capacity by an Index for the Explaining of all the hard and unusual Words and Terms of Art derived from the Greek, Latine, or other Languages, for the Benefit of the English Reader.

With Forty Copper Plates.

The Pharmaceutice new Translated, and the Whole carefully Corrected and Amended.

LONDON,

Printed for *T. Dring*, *C. Harper*, and *J. Leigh*, and are to be Sold at the Corner of *Chancery-Lane*, and the *Flower-de-Luce* over against St. *Dunstans* Church in *Fleet-street*, MDCLXXXIV.

TO THE

Moſt Reverend Father in Chriſt,

And the Right Honourable

HIS GRACE,

GILBERT,

By Divine Providence,

Arch-Biſhop of CANTERBURY;

Primate and Metropolitan of all *England*, and one of His Majeſties moſt Honourable Privy-Councellors.

Moſt Holy Prelate,

THE Eagle will not acknowledge his ſuſpected Chicken, by one only ſign; for it is not enough that it can look againſt the Light, unleſs it be able alſo to behold the Sun's Beams without Winking: and indeed although this our haſty Iſſue, whether by the help of its own blindneſs, or of that doubtful Light in which it liv'd, hath been able to come abroad, yet it hath not ſufficiently given Marks of its true Race, until it might delight its Eye with your Brightneſs, as at the Sun's Beams.

Theſe Meditations or Diſcourſes, though ſeveral times publiſhed, now therefore at length boaſt, that they are able to ſhew themſelves to the Light firſt, with your Sacred Name in the Front, it is then but reaſon, that the ſame *Mecænas*, who hath brought me forth into the open light, from my own darkneſs, and

from the Filthiness and Soot in which I was involved, being condemned among the Metals; should think not it any detraction, to lend to my Works Ornament and Splendor, as well as to the Author and Publisher.

It was by your means (most Noble Prelate) that I obtained the Votes in this Famous University for the Place of *Sidly Professor*; for how small soever my Merits might seem, they were helped by the Greatness and Weight of your Opinion.

I am exceeding conscious to my self, how unfit, being destitute of all help, I came to that Province, both for the Dignity of the Place, of the University, and of my *Mecænas*, yet I believe nothing is to be despair'd of, under so great Auspicies. I would therefore, if there be any thing, at any time, more happily thought of, in the Scrutiny of Nature; and brought forth by me, that it be not referred to my Ingenuity, or (which I might perhaps more truly deserve) my Industry, but to the Influences of my Patron: For to him only he Dedicates and Consecrates himself and all his, who is

Your Graces most Humble

And for ever Obliged Servant,

T. W.

TO THE

RIGHT WORSHIPFUL

Sr Theophilus Biddulph,

KNIGHT and BARONET.

Honoured Sir,

I *Have presumed to Dedicate these my Labours to you, being the* Translation *of a most Worthy and Learned Author, Dr.* Thomas Willis *his Works, out of the* Latine, *into our* Mother Tongue, *for the benefit of my* Country-men: *and knowing you have always been a general, and generous* Patriot, *a lover of your* Country, *and of all manner of* Industry *and* Ingenuity, *I question not, but you will kindly receive this my* Dedication; *though not for my sake, yet for the many* admirable things *that may be found in the* Book *it self, and for the Good and Benefit, which this my Laborious Task may bring to the* Publick. *As I doubt not of your innate Goodness, having already had some particular Experience thereof, so I shall no ways fear an unkind Reception: And although I launch not into the Sea of your Praises, as is the late Custom of* Dedicators *to do, I am perswaded, that this my plain* Epistle *will be as kindly accepted; for I know you to be so modest a Man, as not to love to see all your good Actions, Virtues and Worth, Rhetorically painted and laid open before your Eyes: for as your Worth is too well known, this way to receive any addition; so the praise thereof being needless, will rather cause you to blush, than be any ways pleas'd. But yet I cannot forbear to take notice to the World, that your whole Life has been a true Pattern of* Loyalty *and* Religion, *which in these Troublesome and Distracted Times,*

may be worthily related and mentioned, as a praise-worthy Example for others to imitate and follow: and that you are both a true lover of the Church of England, *your* King, *and* Country, *which you have eminently shew'd in all your Actions, and manifested to the World, by your several Publick Employs, in the behalf of your* Country, *and of the Renowned City of* London, *of which you are a most worthy Member. And no doubt, but that it is for this, your stedfastness in* Religion, *your Loyalty to your* Prince, *your Love to your* Country, *and your uprightness in your* Dealings, *that God hath showered on you all manner of external Blessings, giving you a fair Estate, through your own Industry, Wisdom, and Prudence; a Virtuous Consort, and a prosperous Issue, the fair and flourishing Branches of your Ancient Stock and Family: To all which outward Felicities, I shall pray, That God may also indue your noble Soul with the Celestial and Eternal Blessings and Treasures of the World to come, and that you may be constantly happy both here and hereafter. Honoured Sir,

Your most humble

and faithful Servant,

S. PORDAGE.

THE

THE PREFACE.

THE ſame thing happens to me, about to ſpeak of Fermentation, that once did to a Famous Hiſtorian, when he wrote his Commentary of the *Roman* Empire, to wit, whilſt he endeavoured to draw forth, as it were in a little Table, the Affairs only of that Nation, he was neceſſitated not only to recount the Actions of one People, but of all Man-kind: In like manner, whilſt I did meditate on a few things only concerning the Energy, and the Means of the working of Ferments, I have brought into this Tract, as it were ſwelled up with a certain Ferment, the whole Proviſion, and Dowry of all Nature. Entring upon this Diſquiſition, I thought I had been tyed only to the Bakers Oven, and Brewers Furnace, being condemned to the Mill, not to have proceeded beyond their limits, unleſs by chance, or with leave; but after that I had begun to look more deeply into the matter, I perceived I had gotten a far more large Province: Becauſe it plainly appeared, beſides theſe of Art, very many Works of Nature, to be not only like, but themſelves the effects of Fermentation: For when, for the ſolving of the *Phænomena's*, which are met with about the ſwelling up of the mealy Maſs, and the working of Wine, and of other Liquors, I had Compoſed divers Arguments, Reaſons, and Hypotheſes, I found at length, thoſe firſt begotten Particles, by whoſe Orgaſm or Heat, thoſe vulgar preparations do Ferment, to beget the Cauſes of Motions, and Alterations, in whatever things they are mix'd with beſides; wherefore, I may be pardoned, if I have ſtrayed far from our Propoſition, and have ſeemed to any one, to have heaped together here, too plentiful an Harveſt of Matter, becauſe I was wholly led by the ſame thrid of Ratio-

Ratiocination, and the moſt conjunct Affinity of things, to theſe various and diverſe Concretes. If any one ſhall object, that I proſtitute the unuſual Notions, and almoſt only heard of, in the Shops of the Chymiſts, unhandſomly among the works of ordinary people, I ſay, theſe Principles, which being brought indeed to perform the ſelf moving motions of Natural things, alſo more eaſily to repreſent them to the vulgar capacity, and lay them not only before their Eyes, but even into their very Hands; what of theſe kind of ſubſtances, I call Particles, Men, tho' rude and unskilful, may perceive even by the help of their ſenſes to be in the things: beſides the names of Sulphur, Salt, and Spirit, and the reſt, are more familiarly known, than Matter, and Form, or the four Principles of the *Peripateticks*. As to our Method, and Manner of Philoſophizing, no Man can blame me, if I ſhould not here deſcribe all things according to Rule, and Analytick Patterns; becauſe in this Work, it chances for me to wander, without a Guide, or Companion, in ſolitary places, and as it were in a ſolitude trodden by no footſteps, where I not only make a Journey, but my way alſo: therefore, whenever I deviate, I cannot be ſaid to err, among right Judges of our endeavonrs, who have no Path in which I ſhould Walk, nor could find a Track, which I might fear to miſs.

ON THE
AUTHORS
Medical-Philoſophical Diſcourſes.

THE intricate and hidden Cauſe of things,
Both Peace and Strife by what means Nature brings,
What various motions Bodies do inſpire;
What mixes with the Waters quenchleſs Fire,
What Bonds the Elements together tie,
Before this happier Age unfolded lie:
Things hid to former Ages, and unknown,
The Secrets of the World to all are ſhewn.
Metals dug from the Bowels of the Earth,
Tho they from Phœbus *boaſt their heavenly birth,*
We without light dark and obſcure behold,
And Splendor's found only in burniſht Gold.
Iron unknown lay hidden without light,
By Slaves wrought from the Mine grows dazeling bright.
This to whole Troops confuſion doth afford,
Wit, which firſt fram'd, ſtoops to the Victors Sword.
We thus of old did Nature ſearch in vain,
Our Arts did only ith' outward Bark remain,
But now we her hid Myſteries unfold,
And the great Secrets of the World behold.
Better than us, her ſelf can hardly tell,
What Love doth far within high Mountains dwell.
What flame firſt gives the Marble Quarry birth;
To Metals forms blind Rudiments of Earth,
And the hard child doth to perfection bring:
Why Earth ſhews her rich Treaſures in the Spring;
And ſhines, made brave with her own Native Flowers:
What gentle Gales, and what ſweet moiſtning Showers,
Do on the pregnant Goddeſs Seed beſtow;
Whilſt Heavenly Iris *mounts the cloudy Bow.*
Why Ceres *ſwells with watery Nymphs embrace,*
What Strife, what Wars ſpring from hot Bacchus *Race:*

What

What Vulcan *doth th'* Ætnean *Fornace blow;*
What doth ſoft fires through all Bodies throw;
What Spirit nimbly moves the human frame:
Whence Milky Juice here, there a Purple Stream,
Watering the Body: whence the crimſon Flood;
And the quick Circulation of the Blood.
What hidden fires in Veins and Intrals burn,
Which do the boiling Blood to Feavers turn.
What mixes freezing cold with parching heat,
And makes the different Zones together meet.
Whence comes the Peſtilence with Stygian breath,
Riding on blaſting Winds, and arm'd with death.
What propheſying Humor through the Reins doth paſs,
What colour, and what odour in the Glaſs?
All things lie open now; He did not know
So much to whom Prometheus *did beſtow*
His ſtollen Fires: We now every part
Of the whole Earth compaſs about with Art.
He's happy who cauſes of things can ſhew;
Sacred to Nature, and to Phœbus *too;*
About his Temples Delphic *Laurels ſpread,*
And Flames of Lightning ne'r ſhall blaſt his Head.
Whom Hermes *doth with Sacred Arts imbue,*
VVhoſe Labours, Learning out of Darkneſs drew,
May all's days happy be, may he ſhine bright,
And may he ſtill enjoy Celeſtial Light:
May no Diſeaſe infect with poyſonous breath,
Him, who gains Health from Sickneſs, Life from Death.

OF

OF FERMENTATION, OR THE Inorganical Motion OF NATURAL BODIES.

CHAP. I.

Of the Principles of Natural things.

THere is nothing more rarely to be met with in the Vulgar Philoſophy, where Natural things are unfolded, with the vain figments of Forms and Qualities, than the word *Fermentation:* but among the more ſound (eſpecially of later years) who reſpect the Matter and Motion chiefly in Bodies, nothing is almoſt more uſual. But Fermentation hath its name from Ferveſcency, as Ferment from Ferviment or growing hot. The word is well known in making of Bread, and in the purging of new Wine, Beer, and other potable Liquors: thence it is alſo applyed to other things, which are wont to ſwell or grow turgid, after the ſame manner: that at length it ſignifies, whatſoever Effervency or Turgency, that is raiſed up in a Natural Body, by particles of that Body variouſly agitated.

Bodies of a diverſe Conſiſtency and Habitude, are apt to a Fermenting, *viz.* either Thin or Thick, Liquid or Solid, Animate or Inanimate, Natural or Artificial; in all which is found an Heterogeneity of parts or particles, to wit, there are in them ſome ſubſtances light, and alwaies endeavouring to fly away: and alſo there are others thick, earthy, and more fix'd, which intangle the ſubtil Particles, and detain them in their Embraces, whilſt they endeavour to fly away; from the ſtrivings, and wreſtlings of theſe two twins, in one Womb, the motion of Fermentation chiefly proceeds; but on the contrary, what things do not Ferment, for the moſt part conſiſt of like Particles, and are of the ſame Figure and Conformation, which indeed conſociate among themſelves, without any Tumult or Turgeſcency, lye quiet, and enjoy a deep peace. If Muſt, or new Wine, or new Ale or Beer, be cloſely Bottl'd up, or put into Veſſels of ſmal vent, they will grow ſo very hot, that often the Veſſels are in danger of breaking. But if the ſame Liquors, being Diſtilled by themſelves, and then what is ſeperated, ſhut up, from thence no motion or heat will follow. Wherefore, Diſtilled Waters, hot Spirits, Oyls, fixed Salts of Herbs, and very many other more ſimple preparations of Chymiſts, remain a long while without any Alteration or Fermentation, perhaps ſome of the Particles do evaporate, but the reſt do not tumultuate. In the mean time the juice and blood of Vegetables or Animals, as alſo all Liquors Concreted, and compounded of many things, quickly Ferment, and from thence enter into divers turns of changes. The Spirit of Wine being cloſely ſhut up in a Phial ſhews no ſign of growing hot, but if but a little Oyl of Turpentine be added to this Spirit, the Particles of the Liquors will ſo leap forth, that I have ſeen it break a Glaſs Hermetically

Sealed. All Diſtilled Waters of Herbs, ſo they be kept ſimply in a Glaſs, will remain incorrupt a long time, but if you add to the ſame Sugar or Syrup, it preſently grows ſoure, and is corrupted: Wherefore, that the Fermentation of Bodies may be rightly unfolded, we muſt inquire what thoſe Particles or Subſtances are, and of what Nature, o which mixt things are Compounded, and from whoſe being put together, and mutual ſtrivings, motions for the moſt part naturally proceed.

Altho' there be many and divers Opinions of Philoſophers concerning the beginning of Natural things, yet there are three chiefly deſerve our Aſſent, and Faith, before the reſt. That famous fourfold Chariot of the Peripateticks obtains the chief place, which emulous of the four wheel'd Coach of the Sun, is hurried by a quick paſſage, through the fictitious Heaven of the firſt Matter, and meaſures that vaſt and empty thing, with a perpetual reciprocation: For they ſay, all things are Conſtituted out of Water, Air, Fire, and Earth; and that out of the diverſe tranſpoſition of theſe, Generation and Corruption, as alſo the changes of all alterations whatſoever, do ariſe. In the ſecond place, and next, ſtands the Opinion of *Democritus* and *Epicurus*, which lately alſo hath been revived in our Age, this affirms all Natural effects to depend upon the Conflux of Atoms diverſly figured, ſo that in all Bodies, there be Particles Round, Sharp, Fourſquare, Cylindrical, Chequer'd or Streaked, or of ſome other Figure; and from the divers changes of theſe, the Subject is of this or that Figure, Work, or Efficacy. The third Opinion of the Origination of Natural Things, is introduced by Chymiſtry, which, when by an Analyſis made by Fire, it reſolves all Bodies into Particles of Spirit, Sulphur, Salt, Water, and Earth, affirms by the beſt right, that the ſame do conſiſt of theſe. Becauſe this Hypotheſis determinates Bodies into ſenſible parts, and cuts open things as it were to the life, it pleaſes us before the reſt.

As to the four Elements, and firſt Qualities from thence deduced, I muſt confeſs that this Opinion doth ſomething help for the unfolding the Phænomena of Nature, but after ſo dark a manner, and without any peculiar reſpect to the more ſecret receſſes of Nature, it ſalves the appearances of things, that 'tis almoſt the ſame thing, to ſay an houſe conſiſts of Wood and Stone, as a Body of Four Elements. The other Opinion, which is only a peice of the *Epicurean* Philoſophy, foraſmuch as it undertakes Mechanically the unfolding of things, and accommodates Nature with Working Tools, as it were in the hand of an Artificer, and without running to Occult Qualities, Sympathy, and other refuges of ignorance, doth happily and very ingeniouſly diſintangle ſome difficult Knots of the Sciences, and dark Riddles, certainly it deſerves no light praiſe: but becauſe it rather ſuppoſes, then demonſtrates its Principles, and teaches of what Figure thoſe Elements of Bodies may be, not what they have been, and alſo induces Notions extremely ſubtil, and remote from the ſenſe, and which do not ſufficiently Quadrate with the Phænomena of Nature, when we deſcend to particulars, it pleaſes me to give my ſentence for the third Opinion beforementioned, which is of the Chymiſts, and chiefly to inſiſt upon this in the following Tract, to wit, affirming all Bodies to conſiſt of Spirit, Sulphur, Salt, Water, and Earth, and from the diverſe motion, and proportion of theſe, in mixt things, the beginnings and endings of things, and chiefly the reaſons, and varieties of Fermentation, are to be ſought. If any one ſhall object, That the Atomical, and our Spagyric Principles are altogether ſubordinate, to wit, that theſe, tho at the laſt ſenſible, are reſolved into thoſe, only to be ſignified by Conception; I ſhall not much gainſay him, ſo it ſhews that thoſe Conceptions are real. I being dull and purblind, leave the more accurate to quick ſights, being content to be ſo wiſe as to perform the buſineſs of the outward Senſe with Reaſon: for I profeſs, it pleaſes not me, to deviſe or dream Philoſophy. But that our Work may more rightly proceed, it will be neceſſary, to ſpeak firſt a few things of theſe kind of Principles in general, and of their Affections.

I mean by the name of Principles, not ſimple and wholly uncompounded Entities, but ſuch kind of Subſtances only, into which Phyſical things are reſolved, as it were into parts, laſtly ſenſible. By the inteſtine motion, and combination of theſe, Bodies are begot, and increaſe: by the mutual departure and diſſolution of theſe one from another, they are altered, and periſh. In the mean time, what Particles are gathered together in the Subjects, or depart away from them, will appear under the form of Spirit, Sulphur, Salt, or one of the reſt.

CHAP.

Chap. II.

A Deſcription of the Principles of Chymiſts, and the Properties and Affections of them.

1. Spirits are Subſtances highly ſubtil, and Ætherial Particles of a more Divine Breathing, which our Parent Nature hath hid in this Sublunary World, as it were the Inſtruments of Life and Soul, of Motion and Senſe, of every thing; whilſt they of their own Nature are alwayes enlarged, and endeavouring to fly away, leſt they ſhould too ſoon leave their ſubjects, they are bound ſometimes with more thick Particles, that by entring into them, and by ſubtilizing them, and variouſly unfolding them, they diſpoſe the ſubſtance to maturity, as is to be obſerved in the Vegetation, and Fermentation of Bodies; ſometimes being reſtrained within ſome ſpaces, to wit, the Veſſels or Bowels of living Creatures, they are compelled more often to repeat the ſame meaſures of their motions for the performing the works of Life, Senſe and Motion. From the motion of theſe proceed the animation of Bodies, the growth of Plants, and the ripening of Fruits, Liquors, and other Preparations; they determinate the Form and Figure of every thing, prefixed as it were by Divine deſignation: they conſerve the bonds of the mixture by their preſence; and open them by their departure, at their pleaſure: they bridle the irregularities of Sulphur and Salt. The perfection and ſtate of every thing conſiſts in the plenty and exaltation of Spirits, and the fall and declination, in their want and defect.

As to the Subjects in which the Spirits are, Minerals becauſe they are of a more fixed nature, wanting Motion and Vegetation, are almoſt without Spirits, or at leaſt are contented with a few. For the birth and growth of Vegetables they are required in a more moderate quantity. In the Conſtitution of a living Creature, where there is greater Uſe of Spirits, for Senſe and Motion, a far more plentiful quantity is found. In the works of Art, and chiefly in thoſe which aſcend to perfection, by Digeſtion and Fermentation, there are found to be a ſufficiently great proportion of Spirits: but in all ſubjects whatſoever, whilſt the immerſed Spirits are mingled with the other Principles, their condition or ſtate comes under a threefold conſideration: for they are either depreſſed and ſcattered, and ſo involved with more thick Particles, that they are very little ſeen, or ſhew forth their powers, as in things undigeſted, crude and unripe, may be perceived, in which the Spirits can hardly extricate themſelves into motion, and from which they can hardly be drawn by diſtillation. Or ſecondly, the Spirits flying forth from the thick ſubſtance of the reſt, are full of vigor, ſhake and rightly diſpoſe the more groſs Particles, ſubtilize the thick, digeſt the crude, & bring things to the ſteme or height of maturitity & perfection: or laſtly, Spirits having obtained the height of things, do luxuriate and make excurſions out of the Body: hence thoſe that remain, are by degrees leſſened of their plenty and ſtrength, until being leſs in power than the Particles of the Salts and Sulphur, they are put under their yoak, and by little and little are deſtroyed and driven away out of the Subject; on this threefold ſtate depends the beginnings or rudiments, the maturity and exaltation, and the defect and end of things.

It is obſerved, when the Spirituous Latex is drawn forth of any Liquor by Diſtillation, that the vapor or ſteam is not elevated into dew, that is, comes together in little drops or dew, every where poured forth, as it is wont to do in watery things; but it is divided into ſtreaks, and many little rivulets, and renders the Alembic mark'd in every part with ſtraight lines, only not meridional, leading from the Centre of the top, to the brim of the Circumference. The cauſe of which ſeems to be this, to wit, ſince that the ſpirituous ſubſtance is very ſubtil, it is not eaſily Collected into Liquor, neither is it fixed every where about the ſides of the Veſſel, in its aſcent, as watery Liquors, but alwayes ſtretches further, and unleſs when it comes to the top it ſelf of the little head, doth in no wiſe ſtay; but there the ſpirituous breath, being reſtrained as it were in a punct, and being brought backward, it begins to gather into dew: wherefore, from that top, as it were the Fountain, the Spirits flowing forth on every ſide by ſtreams, deſcend into ſtreaks towards the mouth or brim of the Alembic. And when thoſe lines wholly diſappear, it is a ſign that the ſpirituous ſubſtance is quite ſtill'd forth, and that the watery breath only aſcends.

2. Sulphur is a Principle of a little thicker conſiſtence than Spirit, after that, the moſt active: for when the Spirits firſt break forth from the looſned ſubſtance of the mixture, preſently the Sulphureous Particles endeavour to follow. The Temperament of every thing, as to Heat, Conſiſtency, and amiable frame or contexture, depends chiefly on Sulphur; from hence alſo for the moſt part ariſe variety of Colours and Odors, the fairneſs and deformity of the Body, alſo the diverſity of taſtes. In the Boſom of this, the Spirits immediately, in which as in a Copula, they

are united, by the more hard embraces of the reſt. The ſubſtance of Sulphur, tho leſs ſubtil, is yet of more fierceneſs and unrulineſs than the Spirits are, for this unleſs it be reſtrained, by the embraces of the others, as it were in bonds, and its Particles be detained one from another by the interjection or coming between of the reſt, not only leaves the ſubject, but deſtroys its ſelf, with too impetuous an eruption. Indeed the little bodies of this being gently moved, do cauſe digeſtion, and maturation, ſweetneſs, and many perfective qualities in things: being a little more ſtrongly moved, they induce heat, and exceſs of qualities, inordinations, and chiefly a ſtinking ſavour: but being more impetuouſly moved or ſtirred up, they bring in the diſſolution of Bodies, yea a flame and Burning.

The ſubſtance of Sulphur is never ſeen ſincere, yea it conſiſts not of it ſelf from others, but vaniſhes away into Air: its Particle being concreted and chained together with Salt and Earth, are fixed as it were immoveable, as is ſeen in Metals and ſome Stones: or being Diluted with Spirit and Water, and temper'd together with the reſt, exiſt in motion, by which means (as was before ſaid of Spirit) they are in a threefold ſtate, within the ſubſtance of the mixture: for either firſt of all its little bodies being involved with Salt and Earth, or too much drenched with a watery humidity, are obſcured, ſo that they excerciſe but little of virtue, from whence the humid and cold temper of things exiſts, their qualities are Obtuſe, Dull, and of ſmall virtue or force, and the Bodies leſs apt to be inflamed, as is diſcerned in unripe Fruit, raw juices and green Wood. Or ſecondly, The Particles of Sulphur begin to ſhine forth with Spirit, to be more thickly heaped or rolled together, and to appear eminent above the reſt of the Principles. And ſo by its motion, they evaporate the ſuperfluous moiſture, digeſt Crudities, and induce a warm temper in things, active qualities, a lively force and maturation, or ripeneſs: which kind of exaltation of Sulphur may be obſerved in Wine and Liquors long Fermented, in ripe Fruits, in the Youth and florid Conſtitution of living Creatures. Or thirdly, The Sulphureous Particles being gathered into vigor, grow too hot, looſe the bonds of mixture, and deſire to fly away; and from their diverſe manner of departure and ſeparation, the diſſolution of Bodies variouſly happens: For either they evaporate with Water and Spirit, by degrees, and without tumult, and leave their ſubjects lean and dry, which, when the Sulphur is wholly gone, fall into aſhes: Or ſecondly, in Bodies which abound with Sulphur, when the mixture is looſned, and the Spirits begin to fly away, the remaining Particles of Sulphur are wont to be very much moved, and to grow exceeding hot; and being ſhut up in a thick ſubſtance, are gathered together more nearly, (as in Dung and Hay growing hot) and conceive heat, and ſometimes Burning: breaking forth after this manner, by heaps, and impetuouſly, they breath out a ſtinking ſmell, and bring on a rottenneſs to the ſubject. There is a third manner of eruption, whereby the Sulpureous Particles go forth of Bodies, when they withdraw themſelves, as it were with violence, and being gathered together, break forth into fire and flame: whereby indeed becoming unbridled and untamed, they break all bars or lets, and wholly deſtroy the ſubſtance or frame of the Subject: by this means, by their own and proper effervescency they procure a Burning, as when they being layed up wet, or the wheels of Carts or Axletree, made hot by motion, do fire, or becauſe Sulphur is inkindled by Sulphur: for its Particles being impetuouſly moved, ſhake or move all that's near them, and carry them into the like motion of Conflagration, as ſhall be more fully ſhewn hereafter, when we ſhall diſcourſe concerning the nature of fire.

3. Salt is of a little more fixed nature than either Spirit or Sulphur, nor ſo apt to fly away; but beſtows a Compaction and Solidity on things, and alſo weight and duration; It retards the diſſolution of Bodies, and promotes Congelations and Coagulations, and very much reſiſts Putrefaction, Corruption, and Inflammation; to wit, foraſmuch as it fixes the too volatile Sulphur and Spirit, and detains them in a Body: wherefore ponderous Woods, Stones, Metals, and what abound in Salt, are hardly enkindled, and remain a long while free from Corruption. Not only the duration of the individual, but alſo the propagation of the Species, depends very much upon the Principle of Salt, becauſe the fertility of the Earth, the growth of Plants, and eſpecially the frequent fœtation, and bringing forth of young, in living Creatures, takes their Original from the Saltiſh Seed: hence it is, that *Venus* is ſaid to ariſe from the Sea, and luſt is called Salacity. For Salt having obtained a flux, gathers together, and ſtirs up into motion, the idle, or too much disjoyned little Bodies of Spirit or Sulphur, and excellently keeps them together with it ſelf, for the producing the firſt ground-work of things.

Salt within the frame of the mixture, is either altogether fixed, when its Particles being almoſt deſtitute of Spirit and Water, but bound together with Earth, or Sulphur, or both of them, grow into Stones, Metals, or Minerals of another kind; which fixity in Nature is imitated in making Glaſs, and Earthen Ware: or Salt is looſned from its fixedneſs, to wit, when its Particles being mixed with the other Principles, and chiefly with Spirit and Sulphur, and Diluted with Water, do unfold themſelves, and being diffuſed through the mixture, do Ferment with the reſt: whilſt the little Bodies of the Salt are after this manner put into motion, there is obſerved of them a threefold State or Condition, to wit, of Fuſion, Volatiliſation and Fluxation.

I call

I call the State of Fuſion, when the little Bodies of the Salt being Commixed with the reſt, begin as to their ſmalleſt parts to be diſſolved, and diffuſed, and explicated here and there, through the whole ſubſtance of the mixture, as may be obſerved in the Germination of Plants, in the firſt Conception of living Creatures, and in the beginnings of Fermentations; hence ſpring only a rude and indigeſted formation of things, an ingrateful ſavour, and for the moſt part bitter or biting.

From theſe firſt Rudiments of Motions, the Saline Particles aſcend by little and little, to Vigor and Volatiliſation, together with Spirit and Sulphur: to wit, whereby they run through the whole ſubſtance of the Body, and variouſly move its matter, and diſpoſe it towards maturity. Some little Bodies ſharpen, and ſtir up into motion, others Fix, Eſtabliſh, and Congeal into a ſtony hardneſs. If there be plenty of Spirits and Sulphur, the Particles of Salt, as their handmaids, go about to unite, and aſſociate themſelves intimately with them, that they are not only ſnatched together with them, through all the receſſes of the mixture, but (the ſubject being expoſed to Diſtillation) Salt alſo aſcends in the Alembic, even as the Spirit. From the Volatiliſation of Salt, Beauty, and Fairneſs, and Savour chiefly ſweet, happen in things, as in the florid blood of living Creatures, in ripe Fruits, as alſo in Sugar, Milk, and Hony, we know by experience.

I mean the Fluxation of Salt, when the ſaline Particles, which being firſt gathered together, with Earth, or Sulphur, or aſſociated with Spirit, and ſo remain ſeparated one from another, afterwards the bond of the mixtion being looſened, they become wholly free, and unlooſened from the yoak of the reſt: for ſo they flow together, explicate themſelves through the whole frame of the ſubject, and whilſt Spirit and Sulphur for the moſt part fly away, theſe exerciſe a dominion over the remainder, and induce a ſoureneſs into the whole mixture: by reaſon of this Fluxation of Salt, Wine, Milk, Blood, and Eatable Things, at firſt grateful and ſweet, grow ingratefully ſoure when they begin to Corrupt; and for this Reaſon, all Salts whatſoever, having gotten a Flux, by a violent Diſtillation by Fire (that is, being driven from the Combination of Earth) grow ſoure, than if the ſame ſoure Liquor, be put upon the inſipid dead Head, the Whole laſtly becomes ſalted.

Salt being deprived of the Company of the reſt, (except the Earth) becomes at laſt fixed, as is obſerved in Sea-Salt, or the incineration made of Herbs, whoſe Particles ſo cleave together, that they cannot be pulled aſunder by the ſtrongeſt Fire. when Vegetables are Diſtilled, ſome Saline Particles, though but few, made fit for Fuſion, aſcend with the reſt; and from thence ſome Diſtilled Waters retain a genuine ſavour of the mixture: The parts of living Creatures being expoſed to Diſtillation, yeild a Volatile Salt: when Minerals, or ponderous Woods full of Salt, are brought under by Chymiſtry, the Diſtilled Liquor is like to Salt that hath gotten a Flux, and is very ſoure.

Spirit and Sulphur eaſily unlock the ſubſtance of the mixture, and make way for themſelves; but Salt cannot, unleſs it be ſnatched forth of doors together with the Spirit it ſelf. As Spirit and Sulphur being outwardly applyed, in diſſolving or burning a Body, open as it were the doors for their Companions ſhut within, ſo alſo, Salt Liquors Diſtilled, do the ſame thing: For Stygian Waters ſtrongly Corrode Metals, and are ſeen like a flame put to them, to burn and conſume the ſame.

Salt reſiſts Inflammation, for that it detains the Sulphureous Particles in its Boſom, and hinders them from breaking forth. But excepting that Sal Nitre encreaſes the burning of Sulphur, which indeed happens by accident, becauſe that Salt, as it were an Hermaphrodite, grows very turgid with Sulphureous Particles alſo, combined in the mixture; wherefore, when the Salt is melted by other fired Sulphur, the ſhut up Sulphur, breaks forth with violence, and (like a blaſt from a Bellows) ſhakes the inkindled fire round about, and drives more impetuouſly the ſubject into a Body: In the mean time, if you put the flame to Nitre, it will not be inkindled at all; but being put to a Sulphureous Body, it promotes its enkindling; but the other Salts, leſs turgid with Sulphureous Particles, or rather deſtitute of them, being mixt with Sulphur, hinder its inkindling, and ſometimes put it out.

So much for the active Principles, which effect, as it were, the firſt ground-work of Bodies: thoſe which follow, chiefly beſtow on them Conſiſtency and Subſtance. For from hence exiſt either Liquids or Solids, Small things or Great. For Water and Earth fill the little ſpaces that are empty, through the Combination of the reſt, with their coming between, and amplifie and enlarge the lineaments of the Body, otherwiſe too ſhort and contracted.

4. Water is the chiefeſt Vehicle of Spirit and Sulphur, by whoſe intervention, they conſociate one with another, and with Salt; for the other Principles, being diſſolved by a watery humour, or at leaſt diluted, continue in motion, without which they grow ſtiff, as congealed things.

When Water is wanting, the active Principles meet together too ſtrictly, and mutually rub againſt, and conſume themſelves; and when for this reaſon, the ſuppliment of food is cut off, the Body grows withered. If humidity abounds to much, theſe Elements are eſtranged or diſſociated too much one from the other, wherefore the ſubject becomes ſluggiſh and ſlow, and of

leſs

leſs efficacy, and unapt for motion. Beſides, Bodies too moiſt, are lyable very much to rottenneſs and Corruption; becauſe from too much Humidity the Combination of Spirit, and Sulphur, and Salt, is too loolly effected; that they do not mutually embrace one another, nor are retained with their embracement, in the ſubject. Indeed Water abounding, eaſily evaporates, and then the frame of the mixture being looſened, and the doors ſet open, Spirit and Sulphur eaſily break forth, the way being made, and leave the ſubject, as it were vapid, or made ſharp with Salt: For from hence, the infuſions of Vegetables, Decoctions, Juices of Herbs, and all Liquid preparations, if the quantity of Water be greater then the reſt of the Principles, and improportionate, quickly Corrupt.

Water is moſt eaſily drawn forth out of every thing by Diſtillation, for when Spirit and Sulphur are often intangled with nets of Salt or Earth, they hardly let go their embraces, and are not obedient but to a more intenſe heat, and oftentimes require a previous Putrefaction. Water moſt eaſily, and often with no labour, is driven out of every Body; but moſt often it ſnatches in its flying away, ſome more looſe Particles of Spirit and Sulphur, and carries them with it ſelf, forth of doors.

5. As the interjection of Water in Liquids, ſo of Earth in Solids, fills the empty little Spaces and Vacuities, left by other Principles; for theſe hinder the active Principles from a too ſtreight embrace, whereby they ſhould rub againſt themſelves, and cleave one to another; alſo by its thickneſs, it retains too Volatile things: beſides, it inlarges the due ſubſtance, and magnitude in Bodies.

The more that Earth abounds in any thing, it is ſo much the leſs active, but of longer duration: Hence Minerals endure a long while, then next the greater Trees; in the mean time Animals, and the more ſlender Plants, are but of ſhort age.

In Diſtillations, Earth aſcends the Alembic, almoſt not at all, or but in a very little quantity: for the moſt part it is left, with a portion of Salt, for a *Caput Mortuum*, or Dead Head; therefore it is called *Terra Damnata*, or damned Earth: becauſe, when the other Principles are freed, the Priſon being as it were broken, this is ſtill detained: beſides Earth being deprived of the Company of the reſt, is of no Uſe, nor capable of change, or exaltation.

Thus much for the Elements or Principles of Natural things, conſidered apart, and by themſeves. It follows, that ſome of their Affinities and Conjugations be unfolded: becauſe theſe very ſtrictly cohere with thoſe, and very hardly or not at all are joyned with others. Out of the mutual Combination of ſome, and diſagreement of others, various Affections ariſe, the knowledg of which gives no little Light to the Doctrine of Fermentation.

There is a certain Kindred and Similitude of parts, between Spirit and Sulphur, which are agil or light, and eaſily to be diſſipated in both; wherefore, Spirit being driven forth of the Body, draws abundantly with it Sulpureous Particles, as is diſcerned in Spirituous Liquors Diſtilled out of any thing; to ſome of which if you mingle Water, the Liquor appears as it were troubled with precipitated Sulphur; but the Spirit without the Sulphur is undiſcernably mixed with the Water, which however by reaſon of its Volatility, may be alſo eaſily drawn away and ſeparated by Diſtillation.

Altho Spirit and Sulphur are Principles very reſembling, and (becauſe of of a ready motion) either are inflameable, yet they are not one and the ſame, as is aſſerted by ſome: For Sulphur Copiouſly ſubſiſts in Bodies almoſt deſtitute of Spirit, to wit, in common Sulphur, Antimony, and other Minerals; in which its Particles are very fixed, and of their own nature, almoſt immoveable, which is very far from the Nature of Spirits: For they abounding in any mixture, never lye idle, and alwayes in motion, bring various alterations to the Subject where they dwell; then if they abound in ſtrength, they eaſily and without tumult carry themſelves forth of doors of their own accord. But Sulphur, altho it abound, doth not eaſily evaporate, but hath need of a ſtrong heat, or an actual fire, that may make a way for it; and laſtly, it breaks forth not without a ſtink or burning: yea, if you endeavour to Diſtill Oyly and Fat things, although very Sulphureous, with a moderate Fire, they are wont to yield a Liquor only Wateriſh, and not inflameable; but if we Provoke generous Wine, which ſwells with Spirit, by the gentle heat of a Bath, a moſt burning Water will Still forth, and apt wholly to be inflamed.

Spirit is not preſently joyned with Salt: For Sugar and Salts are ſcarcely diſſolved by the rectified Spirit of Wine, but are after a manner aſſociated by a long digeſtion and circulation; as is perceived in the Volatile Salt of Animals, or Tincture drawn forth from the Salts of Herbs, or of Minerals, by the Spirit of Wine. If that Spirits excel in plenty, and virtue, they aſſume to themſelves, and Volatiliſe the Saline Particles. And therefore the Salt contained in the Juice or blood of Animals, being aſſociated with Spirit, is volatiliſed: Alſo the Spirit of Wine, being Diſtilled by many Cohalations, with the fixed Salt of Herbs, renders it Volatile, and makes it paſs through the Alembic; but if the power of the Salt be greater, it tames the Spirit and fixes it. Hence the blood, being become Salt, by means of an ill dyet, becomes leſs Spirituous. Fixed Salts, and the Oyl of Vitriol fix the Spirits, grown too volatile and unbridled, and Coagulate the Spirit of Wine it ſelf.

But

But Sulphur is a more fit ſubject of the Spirit, by the coming between of which it eaſily is united with Salt and the other Principles; and as Spirit beſt agrees with Sulphur and Water, ſo Sulphur intimately cleaves to Earth and Salt.

As to Sulphur, beſides its affinity with Spirit, it hath a great relation with Salt it ſelf, to the volatiliſation of which it doth not a little help: wherefore in Bodies which abound with a volatile Salt, there is found plenty of Sulphur, as in Amber, Soot, Horns and Bones, as alſo in the excrements of living Creatures; where Salt and Sulphur are in motion, and evaporate from the ſubject, a very ſtinking ſmell is ſent forth; for Sulphur being ſharpned with Salt, pricks more ſtrongly the ſenſory, and ſtrikes it with its ſharpneſs; in the mean time, Sulphur exhaling with Spirit, both pleaſes the ſenſe, and excites a very pleaſant ſmell.

Sulphur is as it were diſtracted between Spirit and Salt, and adheres at once to both parties. In the Diſtillation of Amber, Turpentine, Harts-Horn, and the like, a certain leſſer part of Sulphur, being united to Spirit, firſt aſcends and cauſes a Yellow Oyl, or clear Liquor of a grateful ſmell: the other part of Sulphur, being joyned to the Salt, is driven forth in the ſecond place, and is Diſtilled with a moſt ſtinking ſmell, in the form of a red or black Oyl: In like manner, in the Circulation of the Blood, a pure and delicate portion of Sulphur, being mixed with the Spirit, ſupplies both the Animal and Vital Spirit with matter; the other more thick part, being Boyled and Roſted with Salt, is laid up in the Choledock Veſſels (or belonging to Choler) as it were a certain excrement ſeperated from the Blood. As Spirit does not eaſily Cohere with Salt, ſo Sulphur does not with Water: wherefore Fat and Oyly things, as alſo Gums and Sulphureous Reſines, either ſwim upon the Water, or ſink down to its bottom. But Sulpureous things, Salt coming between, are commixed with a Watery Liquor, as we ſee Oyls imbued with Sugar or Salt, to be diſſolved in common Water, which otherwiſe would flow ſeparate.

Sulphur is not ſo tractable in Diſtillation, as Spirit, Water or Salt: for the Particles of this, being very Viſcous, ſtick together among themſelves, and alſo to others, that they cannot eaſily be pulled from their embrace. Hence among Sulpureous things, there are ſome, which are not forced, but by a ſtrong and burning heat, into a ſtinking Oyl, and very empyreumatick, or ſmelling of Fire: But others, more pertinaciouſly cleaving together, are not to be looſened by Diſtillation, but are only broken into integral parts; and ſo aſcend under the form of a dry Breath, as common Sulphur, Benzoin, Camphor, and the like.

Salt, beſides its affinity with Sulphur, is alſo moſt ſtrictly united with Earth; wherefore, Stones, and the more hard Minerals, conſiſt chiefly of Salt and Earth. The Acid Spirits of Minerals, (which are only Salts reſolved into Liquor by Diſtillation) if at laſt they be poured on the *Caput Mortuum*, Cohere with a ſtrict embrace to it, that there will be need of a moſt ſtrong Fire, to drive them forth again. Alſo in Glaſs, the union of Salt and Earth is ſo ſtrictly made, that it will not ſuffer a Divorce by any means. Salt alſo is moſt eaſily Diſſolved in Water; and it melts of its own accord, in a moiſt Air: and theſe are as eaſily ſeperated one from another.

By reaſon of theſe Combinations, theſe Principles have got various Appellations and not Congruous in their own Nature to themſelves: For Sulphur, foraſmuch as it is Aſſociated with Spirit, is called pure and ſweet; when with Salt, impure and ſtinking, for as much as with Salt and Earth, it is called thick and Earthly; when the Spirit aſſumes to it ſelf Sulphureous Particles in a moderate quantity, it is ſeen to be ſweet; when ſaline, ſharp; when both, bitter. Salt has a diverſe diſpoſition, and is known by many names, by reaſon of its various mixture with the other Elements, and chiefly with Earth; for beſides the Titles of Fluid, Fixed, Volatile, for this reaſon it is termed Marine, Aluminous, Nitrous, Vitriolick, Armoniack, or of ſome other kind. By ſome, theſe kind of Conjugations are eſteemed, but wrongfully, as ſo many divers Principles, when they are but ſimple mixtures, by the coming together of the firſt Element, and being looſened by Diſtillation they openly ſhew their Race, from whence they are. For all ſalts whatſoever being driven into a Flux by the Fire, ſhew Liquors very near of Kin one to another, to wit, Acetous: by the like means Spirit and Sulphur are compelled to put off their masks, and to reſume the Native Species common to each.

And ſo much for the Principles of Natural Things, and of their Affections and Conjunctions. It is abundantly manifeſt, that theſe kind of Subſtances are in every Body, (beſides the Analyſes of Bodies Chymically inſtituted) alſo from the Mutations, and effects of Things, which happen of their own Nature. When Muſt is ripened into Wine, is not Spirit, a Sulphureous part, alſo Salt, and Earth Conſpicuous to our Taſt and Eyes, beſides the Water, Liquor? Alſo the Juice of every Plant being exalted by Digeſtion, exhibits the ſame ſincere, and is as it were diſtinct: what is greater, things ſubject to the Flame, when they ſeem to be burnt, and reduced almoſt to nothing, they go into theſe kind of Particles; beſides the ſalt remaining in the Aſhes, the ſmoke and Flame grow together into ſoot as it were a Meteor, in which are comprehended together, Spirit, Sulphur, Salt, Water, and Earth, as it were in a certain compendium of the mixture. For the active Principles abound in Soot, more than in any other inanimate Body.

But

But becauſe with ſome there hath ſpread a certain ſuſpition, that thoſe our Principles, chiefly the Saline and Sulphureous, are to be produced for the moſt part by Fire, and are no wayes to be found in mixt things, unleſs after the coming between of that: I will witneſs to you in ſome inſtances, that the thing is plainly otherwiſe. Concerning the firſt, It is commonly known, that the Aſhes of every Plant, being once Elixivated, or made into a Lye, if it be afterwards Calcined, will not yield any thing of Salt; beſides if Concretes being Diſtilled, Exhale or Breath forth a very ſharp or acid Liquor, their Calx is not ſaltiſh; and on the contrary when the Salt being Volatiliſed or brought to a Flux, aſcends the Alembic, you ſhall ſeek for it in vain in the dead head. To prove the exiſtency of the ſulphureous Principle in Vegetables, take Guaiacum, or a peice of any other ponderous Wood, & being put into a Glaſs Retort, draw it forth by degrees; it ſhall exhibit, together with an Acid Liquor (which Water is ſaltiſh) in great quantity, a blackiſh Oyl (which part of it is ſulphureous.) It appears from hence that this was in the Body before the Diſtilling, and in no wiſe produced by its Operation, becauſe if you proceed after another Manner, that the Sulphur may be taken out of the Concrete before Diſtillation, the Liquor that comes forth will be almoſt wholly deprived of its Oylineſs: Wherefore, if you pour Spirit of Wine to thoſe Chips of Wood, it will Extract in great quantity, by this Menſtruum, a pure Reſine, which is the ſulphureous part it ſelf; then if you Diſtill (as before) in a Retort, the remaining Chips being waſhed in common Water, and dryed, you will have a very little Oyl only. What is more to be admired, and confirms alſo more fully the truth of this kind of Origination, ſome Bodies, which being almoſt deſtitute of Spirit and Sulphur (becauſe chiefly Volatile) conſiſt chiefly of Salt, Earth and Water, are ſeparated into the Elements by Diſtillation: the ſame mixture in number, and wholly known by the ſame accidents, is reſtored to them, being mingled together again; for example, if you diſtill Vitriol in a Reverberating Furnace, you will have a Phlegm almoſt inſipid, or a Watery part, then a Liquor very ſoure, or a Salt having gotten a Flux, and in the bottom, a Red Earth, and finely Purpled: this being rightly performed, if the two Diſtilled Liquors be poured to the dead head, you ſhall have the ſame Vitriol as you had before, and again revived, in the ſame Colour, Taſt, yea and almoſt in weight. In like manner you may proceed, with the ſame ſucceſs, with Nitre, Sea-Salt, Salt of Tartar, and perhaps with Alum and other Minerals; ſo that thoſe Concretes, which conſiſt of fixed and ſtable Elements, may like a Mechanick Engine be pulled into peices, and preſently without hurting the Machine, be reſtored or made whole. But there is enough ſpoken concerning the Principles of Natural Bodies. Theſe being thus premiſed, we will proceed to the thing propoſed in the beginning, to wit, the Doctrine of Fermentation.

CHAP. III.

What Fermentation is: Its Diviſion as to the Subjects; and firſt of Minerals.

FErmentation is an inteſtine motion of Particles, or the Principles of every Body, either tending to the Perfection of the ſame Body, or becauſe of its change into another. For the Elementary Particles being ſtirred up into motion, either of their own accord or Nature, or occaſionally, do wonderfully move themſelves, and are moved; do lay hold of, and obvolve one another: the ſubtil and more active, unfold themſelves on every ſide, and endeavour to fly away; which notwithſtanding being intangled, by others more thick, are detained in their flying away. Again, the more thick themſelves, are very much brought under by the endeavour and Expanſion of the more Subtil, and are attenuated, until each of them being brought to their height and exaltations, they either frame the due perfection in the ſubject, or compleat the Alterations and Mutations deſigned by Nature.

Fermentation is an action or motion meerly Natural, and what doth perform it, are only Particles Naturally implanted in the Concrete; yet as to the ſubjects in which they are found, it is wont to be variouſly diſtinguiſhed. And either things of Nature are ſaid to Ferment in a threefold Family, of Minerals, Vegetables and Animals; or the Works of Art, to wit, when Actives are applyed to Paſſives by an outward Agent. Though the Term and Conſideration of Fermentation, are chiefly due to Artificial things, and things made by Hand; yet it will not be from the purpoſe, to ſpeak firſt ſomething of Natural Things, that a Compariſon being made of either, the Truth of our Hypotheſis, and the certainty of the Principles may be confirmed. But this only lightly by the way, in this place I ſhall paſs over, becauſe their more full handling belongs to Phyſiology, or the Diſcourſe of Natural or Phyſical Things.

In

In the first place, as to Minerals, altho in the bowels of the Earth, the Fermentation is less conspicuous than in the Superficies, yet it easily appears that the Elementary Particles, or the Fermentative Principles, are included in the depth of the Earth, as in a certain pregnant Womb: which there constitute Concretes, and things gathered together, by strict Embraces, the Productions of Minerals; but being loosned, and moved in the Bosom of the Earth, or exhaled upwards, cause the appearances of Meteors.

First, The Generation of the more hard Minerals, induces rather Congelation than Fermentation; because indeed these Principles, growing together in every Subject, are so fixed, and as it were bound together in Bonds, that they are not able any wayes to move themselves, or to depart one from another. This kind of fixation chiefly depends on the plenty and greater proportion of Salt and Earth (sometimes with an addition of sulphur) than there is of spirit or water, to wit, salt and earth, being most smally broken, and resolved even into a Vapour, lay hold of one another, and stiffen into a hard matter, and at last not to be loosned; almost after the same manner as making of Glass, and the burning of Bricks and Earthen Ware, are performed. For Glass consists of Salt and Earth, which when broken into most small bits, by a very intense Fire, they suffer a flux, they mutually lay hold of one another, and so strictly and intimately come together, that they are never to be parted. Glass is more fragil, or easy to be broken, then Earthen Pots, or Minerals, because it has a greater plenty of Salt, than of Earth, which is more plentiful in Earthen Ware, and in Minerals: To some of which, also happens a modicum of Sulphur, and for that reason they are more tenacious and ductil; as is to be observed in Metals, when in the mean time stones, and what contain little of Sulphur, are fragil, and apt by every stroke to fly to peices. In Vitrification there is need of a violent Fire, for the fusion of the Salt and the Earth (whose Particles, as is commonly said, are the Pestles of the Chymists) but within the Bowels of the Earth, there is not required such a fusion of Fire for the Concretion of Minerals, because Salt and Sulphur exist, being naturally resolved into most simple Particles; which, when they lay hold on the Earth, easily stiffen into Metal, or into a stony hardness. There are some Fountains found out, which, for that they flow with a primitive Salt, and resolved into small Particles, whatever Bodies are immersed therein, they cause them presently to become stony. We have read also, of Men changed into Stones, yea a whole City to have been stiffened into a stony substance, by the Air, or by some Vapour, brought forth of the Earth: The Faith of which thing is left to the Authors.

Meteors are made out of the same Principles by which Minerals are made, and conceived almost in the same Womb: but loosned from Concretion wandring here and there, and diversly fluctuating: or which being included in Subterraneous Vaults, and there moved, produce divers Springings up of Fountains, or ebullitions of hot Vapours; or exhaling from the Dens of the Earth, and being mixt with Airy little Bodies, they cause within the Region of the Atmo-Sphear, as it were a diverse fashioned Landskip, of Clouds, Winds, and the appearances of other things, in the Superficies of the Earth, or on high: in either there are highly active Principles chiefly Salt and Sulphur. Spirits are either deficient in Meteors, even as in Minerals, or are found only in a very small quantity or proportion: to wit, they are almost wholly excluded from these, by reason of the strict frame of the subject, which doth not easily yeild space and passage for their motion; also they abstain from those (*viz.* Meteors) by reason of the lax, and wholly loose structure of Matter, from whence they, who are mighty in swiftness, easily break forth, and desire to fly away.

Within the Bosom of the Earth, the Saline Particles being loosned, even into a Vapour, and then kneaded with an Earthy Matter or the moistening of Waters, they cause Eruptions of Fountains, and Acidulous or Spaw Waters, which resemble the disposition of Vitriol, Alum, Nitre, sometimes of Iron or Copper. Also the Sulphureous little Bodies being loosned, and gathered together, enkindle an Heat, and sometimes Subterraneous Fires; by whose Breaths the Dens and Caverns being made Hot, like an Hot-House, whilst the Watery humours pass through them, they from thence conceive their Heat, and supply the Springs of Hot Fountains for Bathes.

In like manner, in this visible and Ethereal World, Vapors both sulphureous and saline, and of a diverse Kind and Nature, perpetually breath forth, and are diffused through the whole Region of Air. From hence the diversity of Winds, the vicissitudes of Cold and Heat, Rain, Snow, Hail, Dew, and hoar Frost, and what are of this Nature, have their Origine. Concerning the particular Instances of these, the famous *Gassendus* may be consulted; who, in his *Epicurean* Philosophy, most aptly deduces the Phænomena, almost of all Meteors, and the Reasons of them, from the Exhalations of Sulphur and Salts, either Nitrous, Vitriolick, Aluminous or Almoniack.

CHAP. IV.

Of Fermentation for as much as is obſerved in Vegetables.

IN Vegetables Fermentation is yet more plainly diſcerned; for whilſt they Bud forth, Grow, Flower, bear Fruit, Ripen, Decline and Die, we may obſerve the divers motions of Particles or Principles, their various Habits and Tempers. I intend not here to deſcribe the ſeveral ways and proceedings of theſe. It will be ſufficient, for the unfolding the Doctrine of Fermentation, to take notice of ſome chief Inſtances concerning this Subject.

It is manifeſt by dayly Experience, that all Plants whatſoever, expoſed to a Spagyrical or Chymical Operation, may with little labour, be reſolved into the aforeſaid five-fold Elements: But in ſome there is found a greater plenty of ſalt, in others of ſulphur; in ſome ſpirits abound: Water and Earth are in moſt proportionated according to the Bulk and Magnitude of the thing. Plants, in which ſalt abounds, with a mean of ſulphur, and a little quantity of ſpirits, are for the moſt part of long Age, ſomewhat big, or flouriſh all the Winter, or though their Leaves fall, they keep a Nutricious Juice under the Bark: Of which ſort are the Oak, Aſh, Elm, Box-Tree, and all ponderous Woods and Shrubs.

In ſome ſulphur abounds, with a little ſalt and ſpirit, as are the Pine, the Firr-Tree, Cyprus-Tree, Juniper, Ivy, Olive, Cedar, and Myrtle-Trees, and all reſinous Plants; which for the moſt part have a ſweet ſmell, and are perpetually green, by reaſon the Juice wherewith they are nouriſhed, is viſcous, and not eaſily to be diſſipated. In others, beſides plenty of ſalt and ſulphur, ſpirits alſo are found in a greater proportion; as are Fruit-bearing Trees, and eſpecially the Vine, from whoſe Fruit, the Juice being wrung out, and purified by Fermentation, grows very big with ſpirit. Of this Rank are Plants for the moſt part Medicinal; alſo ſuch as produce curious and odoriferous Flowers; but in ſome, Water and Earth luxuriate in too great a quantity above the other Elements, as in cold Plants, and ſuch as grow in too rank a ſoil.

The Germination of Plants happens after this manner, either it is made out of the Seed, Root, Trunk, or of its own Nature, from the naked Matrix of the Earth. Firſt, the ſpirit being ſhut up within, by the ambient Heat and Moiſture looſening the frame of the mixture, being looſened, it preſently endeavors to fly away; but being held back in its flight, by the more thick Particles of the reſt, ſtretches forth more largely its Den, and together with the other Principles, with which it is bound, thruſts forth on every ſide into length and breadth; even as a little bundle of Silk, being contracted into wrinkles and folds, is opened here and there; in the mean time, the little ſpaces left by the enlargement of the ſpirit, and as it were made hollow, are filled up by the next Matter, driven even into the Vacuities. And after this manner the Architect Spirit, with its Miniſters, ſalt and ſulphur, ſtill ſtretching forth it ſelf, like a Snail, frames for it ſelf an Houſe, whoſe Inhabitant it is, and by dilating it ſelf, ſtretches forth that, until at laſt it hath wrought the Plant into the due Bulk and Figure deſigned by Nature.

You may take notice, that the times of the year, for the Budding, Flowering, Ripening, and Decaying of Vegetables, are of great efficacy and virtue; all the Winter, the Womb of the Earth, as it were ſhut up, is almoſt barren; for the ſpirituous Particles, which are wont to actuate the reſt, and as it were to lead the Dance of Natural Motions, are either chaſed away by the Winters Cold, or being congealed in their ſubjects, are fixed, wherefore at this time Germination and Vegetation are very rare, unleſs that ſome irregulat Plants, which are compoſed of plenty of ſpirit, ſalt and ſulphur, dare to break forth. But in the Spring, when the Bowels of the Earth begin to be a little warm by the Vicinity of the Sun, preſently they are impregnated with a wonderful Fœcundity, and produce the effects of their ſeminality. Not only the ſuperficies of the Earth, but alſo the Water and Air, every where grow big with ſpirituous particles, which, as it were, raiſe up from the dead the little Bodies of ſalt and ſulphur, and bring them into Motion: Therefore, beſides that the Plants Bud, the Juice and Blood of living Creatures is quicker, and more apt to abound. At this time the Birds and Fiſhes build their Neſts, and bring forth Eggs; alſo we may perceive in our ſelves the Blood to flow high in the Veſſels, and uſually to Ferment too much. For all things are then full of this Ethereal ſubſtance, and the whole Bulk of Nature, as it were, inſpired by a lively Fermentation, is abundantly fruitful of Motions and Generations. Yea, theſe our Principles, at firſt ſeparated and diſperſed one from another, led as it were by an Appetite of Copulation, enter into mutual Marriages, and being married together, almoſt by infinite Embraces, cauſe a moſt ample ſeeding and germination of the Herby State.

At

At the beginning of the Summer (and perhaps in ſome ſooner, in ſome later) when ſufficient time hath been granted for the ſtature and magnitude of every Plant, and that it is now come to the height of increaſe, it behoves Nature to perfect her Work, and to Cook and ripen the ſubſtance, as yet rude and undigeſted; wherefore the active Principles leiſurely extricate themſelves from the more thick, and creep forwards towards the top, there being placed with a mutual increaſe, they are formed into Flowers and Bloſſoms, from which at length (for that they are of a ſoft and light texture) ſpirit and ſulphur eaſily evaporate, and the frame of the mixture quickly decays: But Nature careful of the perpetuating every thing, when it cannot keep for ever the Individuum, is ſo provident, that the ſpecies may not wholly periſh: Wherefore ſhe inſtitutes new and more firm and laſting Combinations of ſpirit, ſalt and ſulphur; for ſhe ſelects from the whole ſubſtance of the Plant the more noble and highly active Particles; and theſe being gathered together with a little Earth and Water, ſhe forms in the Seed, as it were the Quinteſſences of every Plant; in the mean time, the Trunk, Leaves, Stalks, and the other Members of the Plant, being almoſt quite deprived of the active Principles, are much depauperated, and are of leſs Efficacy and Virtue.

About Autumn, after the Seeds are framed (as it were pledges left in memory of the Plant) the particles of ſpirits, ſalt and ſulphur which remain, being now placed in their ſtrength or exaltation, endeavour a Diſſolution and Departing one from another. And firſt of all, the ſpirits evaporate by degrees with the watery Humor, through the doors ſet open by the ſummer Sun, with which the more pure parts of the ſulphur make alſo their Journey; in the mean time, the ſalt, being fixed with the Earth and more thick ſulphur, is left behind; wherefore in moſt the Leaves fall at this time, and in thoſe of a tender and light conſtitution, the Principles are wholly diſſipated, and the Trunk and ſtalk, together with the Root, wholly die. In ſome, after the falling of the Seed with the Leaves, the ſtalks wither; in the mean time the Principles which may renew the Plant in the next Spring, are preſerved in the Root.

Alſo Winter coming on, the face of things is wholly changed; and the Elements, which in the Spring did affect to be joyned, and to marry one with another, ſeek nothing more than Divorces. The Spirits fly away from very many things, and wander in the Air; in the mean time the particles of ſalt and ſulphur lie as it were benummed and aſleep. Not only the Bodies of Vegetables, but of very many Animals, are left as it were dead all the Winter, till they are raiſed again to the Life by the Spirit, returning with the Vernal Sun, and as it were animated anew. But this little Branch being made concerning the Vegetation of Plants, it is now fit that we proceed on our Journey to Fermentation by the Rule of our before eſtabliſhed Method, to what is to be obſerved concerning the Parts and Humors of Living Creatures.

Chap. V.

Of things to be obſerved of Fermentation about Animals.

IT is ſo certain that the Bodies of Animals conſiſt of the aforeſaid Principles, that it wants no proof: For they ſo plentifully ſwell up with ſpirit, ſalt and ſulphur, that their Particles are obvious to the ſenſe; wherefore they are moved with a more ſwift motion, and more excellent ſenſes of Life and functions of Heat in the ſubjects in which they are implanted, are enlarged. It would be too much labour, and tedious here to deſcribe the ſeveral manners and proceſſes of Fermentations. The firſt beginnings of Life proceed from the Spirit Fermenting in the Heart, as it were in a certain little punct. The motion of this is not as in Vegetables, ſlow and inſenſible, and only to be known by their increaſing; but preſently becoming rapid, is conſpicuous to the Eyes; becauſe the Spirit leaping from the punct, as from a Priſon, being ſtirred, and having obtained the Vehicle of Blood, ſwiftly runs forth; and leaping forth, it cannot wholly fly away, it makes hollow ſpaces for it ſelf in the thick ſubſtance, in which it is included, for its excurſion, being compelled ſome other way backward. Laſtly, being returned to the Heart, it Ferments the more, wherefore it ſtretches forth further the ſpaces of its Excurſion, and ſo eaſily makes an hollow way for its return back; and after this manner, for the carrying about the Blood, Arteries and Veins, as Channels and Rivulets are framed through all the parts of the Body: and on ſuch a Viciſſitude of Motion, or Reciprocation, depends the life of living Creatures, which that Nature might preſerve a long while, ſhe placed the Ferment in the Heart, by whoſe inſtinct, or endeavour, the Blood grows impetuouſly Hot, and as it were enkindled into a Flame by its Deflagration, diffuſes the *effluvia* of its Heat round about on every ſide: for by the Fermentation, or Accenſion which the Blood ſuffers

in the Boſom of the Heart, very many Particles of Spirit, Salt and Sulphur, endeavour to break forth from its looſned frame: by which being much rarified, and like Water boyling over a fire, the moved and boyling Blood is carried through the Veſſels, not without great Tumult and Turgeſcency. We would ſpeak more in this place, both of the Natural Fermentation of the Blood, and the Feaveriſh, but that we reſerve this Conſideration for a peculiar Tract, where we Treat of Feavers.

Beſides this Ferment conſtituted in the Chimny of the Heart, upon which the motion and heat of the Blood very much depends, there are others laid up every where in the Bowels, of a diverſe diſpoſition, by the help of which, both the Chyle (which is the Rudiment or Beginning of the Blood) and the Animal Spirits, its Quinteſſence, are truly framed. There are others alſo which ſerve for the perfecting the Blood, tranſmuting it into other Liquors, and freeing it from Excrementitious Matter: It will be too far from our propoſed method, to wander, to inſiſt upon each of theſe, and to reap anothers Harveſt: Wherefore I will only add in this place, ſome ſelect inſtances, which may illuſtrate the Doctrine of Fermentation.

It is commonly received, that the Concoction of the Chyle, in the Ventricle, is made by the means of a certain Acid Ferment: That ſuch a thing is, the Acid Belching in a full Stomach, and the want of it in the loſs of Stomach, in Feaveriſh and Dyſenterical people do teſtifie, *&c.* and its reſtitution a ſign of Health: to which may be added this Obſervation, Chalybeat Medicines being taken at the Mouth, a little after excite a Sulphureous ſavour in the Throat, as if hard roſted Eggs had been eaten: which ſeems wholly to be made by the Acid Ferment of the Ventricle, gnawing the Iron, even as Spirit of Vitriol, being ſprinkled upon the fileings of Steel, excites ſuch a ſtinking and Sulphureous Odor. Some ſay this Ferment is breathed into the Stomach from the Spleen, but by what means that may be done, doth not yet appear by Anatomical Obſervation. It ſeems not improbable that this Ferment is implanted in the Ventricle, that it is only made by ſome remains of the perfected Chyle, which fixed in the folds of the Ventricle, and there growing ſowr, puts on the Nature of Ferment; even as a portion of Dough being fermented or levened, and kept to a ſowrneſs, becomes a convenient Ferment or Leven, for the making of Bread. In like manner this kind of Acid humour being prepared from the Aliments, and long carried in the Ventricle, promotes the Concoction, and ſubaction or ſubduing of the Food; for Acid things, which are full of Salt, carried out to a Flux, excellently conduce both to the Fermenting and Diſſolving of Bodies: Wherefore by the action of this, Salt and Sulphur, with which eatable things very much abound, are broken in the Ventricle, and are reduced into very ſmall parts. The Chyle being after this manner Fermented, acquires a Milky colour, by reaſon that the Sulphureous Particles are diſſolved together with the Saline, and mixed with the Acid Ferment. For if you pour an Acetous humour to any Liquor impregnated with Sulphur and volatile Salt, it preſently grows white like Milk; as may be diſcerned in the preparing the Milk of Sulphur, or the Reſinous extracts of Vegetables. Yea, the Spirits of Harts-Horn, or Soot, being very full of Volatile Salt, if they be poured to any Acid Liquor, or ſimple Water, acquire a Milky colour.

Concerning this Ferment hid in the folds of the Ventricle, it is obſerved, that it is after various manners, and changes the Aliments by diverſe means: for tho in a ſound Conſtitution it is indifferently Acid, and chiefly owes its force and energie to the Salt being brought to a Flux; yet it often declines from this laudable condition, and contains in it ſelf either too much of ſowrneſs, or leſs than it ought to have: In the former Caſe, where the Salt hath got too ſowr a Dominion, all things taken in, (the Saline Particles being carried forth to a Flux, and the reſt unduly brought under) preſently grow ſowr; as moſt often happens in Hypocondriack Diſtempers: on the other ſide, where the Volatile Principles obtain the firſt place, (Fermentation being too haſtily made) the Sulphureous parts of the Chyle are ſuddenly, and as it were forceably exalted; and the unconcocted of the Saline, paſs into Choler: which ordinarily happens to thoſe abounding with bitter Choler. They therefore who have the Ventricle affected after this latter manner, ſweet and fat meats being eaten, they are troubled with a bitter and bilious Taſte: Again, they who ſuffer the contrary diſpoſition, altho they eat the moſt ſimple food, ſend forth plentifully Acid and ſtinking belchings: and indeed this ſeems to come to paſs even after the ſame manner, as when a little too much Yeſt is put to the Batch of Dough, it becomes bitter; or when too great a Portion of ſowr Ferment, or Leven is put to the ſame Dough, the Bread from thence contracts a mighty ſowrneſs.

As the Blood in the Heart, and appending Veſſels, the Chyle in the Ventricle, ſo the Animal Spirit is wrought in the Brain, whoſe Original and Motions are very much in the dark. Neither doth it plainly appear, as to the Animal Spirit, by what workman it is prepared, nor by what Channels it is carried, at a diſtance, quicker than the twinkling of an Eye. But it ſeems to me that the Brain with Scull over it, and the appending Nerves, repreſent the little Head or Glaſſie Alembic, with a Spunge laid upon it, as we uſe to do for the highly rectifying of the Spirit of Wine: for truly the Blood when Rarified by Heat, is carried from the Chimny of the Heart, to the Head, even as the Spirit of Wine boyling in the Cucurbit, and being reſolved

ſolved into Vapour, is elevated into the Alembic; where the Spunge covering all the opening of the Hole, only tranſmits or ſuffers to paſs though the more penetrating and very ſubtil Spirits, and carries them to the ſnout of the Alembic: in the mean time, the more thick Particles are ſtayed, and hindred from paſſing. Not unlike this manner, the Blood being delated into the Head, its Spirituous, Volatile, and ſubtil Particles, being reſtrained within by the Skull, and its *Menynges*, as by an Alembic, are drunk up by the ſpungy ſubſtance of the Brain, and there being made more noble or excellent, are derived into the Nerves, as ſo many ſnouts hanging to it. In the mean time the more craſs or thick Particles of the Blood, being hindred from entring, are carried back by Circulation: But the highly agil and ſubtil Spirits enter the ſmalleſt and ſcarcely at all open Pores of the Brain and Nerves, and run through them with a wonderful ſwiftneſs: for there is need only of ſuch Receptacles and Channels, for the Animal Spirit, in which there are none, or at leaſt very ſmall cavities or holes, otherwiſe the blood or excrementitious humours, their followers and companions would not be excluded. Alſo, beſides, if theſe Spirits ſhould run about through too open and looſe ſpaces, being eaſily diſſipated, they would fly away: wherefore, when there is need of a Pipe for the tranſmitting of blood, or ſerous water, the Spirit of Wine runs rapidly through the ſecret paſſages of the Inſtrument or Leather. Neither doth the more ſtrict frame of the Brain and Nerves ſerve only for the ſtraining of the ſubtil from the thick, and the pure from the impure; but alſo that ſpirituous and moſt ſubtil Liquor, being as it were diſtilled from the blood, gets yet a farther Perfection in the Brain; for there being inſpired by a certain Ferment, whereby it is yet more volatiliſed, it is made more fit for the performing the offices of motion and ſenſe. Becauſe the ſubſtance of the Brain is exceeding full of a Volatile Salt, which is of great Virtue for the ſharpning and ſubtilizing the Spirits; therefore the Spirits of Harts-Horn, or of Soot, are far more penetrating than Spirits of Wine.

The Seminal Veſſels and Genital Parts, do ſo ſwell up with Fermentative Particles, that there is nothing more: here Spirit, Salt, and Sulphur being together compacted, and highly exalted, ſeem in the Seed to be reduced as it were into a moſt noble Elixir. Theſe kind of active Principles do not only Ferment in the Womb, for the forming of the Child or Young ones, but alſo as it were, with a living Ferment, they inſpire, through all the Body, the whole Maſs of blood, that it may be more Volatile, and more ſharply hot: Wherefore in Women who have the Ferment of the Womb in good order, their face is furniſhed with a curious and flouriſhing colour, their heat is more lively and copious; moreover, the maſs of blood growing too rank, there is need of emptying it every Month by the flux of their Courſes; but when this Fermentation from the Womb is wanting, both Virgins and Women become Pale, and and as it were without blood, ſhort-winded, and unfit for any motion. Alſo in men, from the ſeminal Ferment, happen abundance of heat, great ſtrength, a ſounding Voice, and a manly eruption of beard and hair; by reaſon of the defect of this, men grow womaniſh, to wit, a ſmall Voice, weak Heat, and want of beard are cauſed.

Since we Treat of Ferments, which are found in the Animal Body, we may here opportunely inquire, what is the uſe of the Spleen: concerning which all good things are ſaid by ſome, that it is as it were another Liver, and ſerves for the making of blood for the *Viſcera* of the lower belly: it is by others reputed to be of a moſt vile uſe; that it is the Sink or Jakes, into which the feculencies of the blood are caſt. By reaſon of its ſtructure, we make this ſort of conjecture; becauſe the Arteries, do carry the blood to this, and the Veins bring it away, neither any other thing is carried in, or conveyed out; and for that its ſubſtance is filled with black, and ſtagnating blood, it ſeems that it is as it were a ſtore-houſe for the receiving of the earthy and muddy part of the blood; which afterwards, being exalted into the Nature of a Ferment, is carried back to the blood for the heating of it: Wherefore, while the blood being carried by the Arteries, enters the Spleen, ſomething is drawn from it, to wit, the muddy and Terreſtial Particles, which are as it were the dregs, and *Caput Mortuum* of the blood; that by this means the whole Maſs of Blood, might be freed from the Melancholick or Atrabilous Juice; which is ſeparated in the Spleen, even as yellow Bile or Choler, is in the Liver: wherefore, for the moſt part the Spleen is of a black or blewiſh colour, by reaſon of the feculencies or dregs there laid up. But as this Juice depoſited in the Milt or Spleen, is not altogether unprofitable, but by reaſon of the plenty of fixed ſalt, is of a very Fermenting Nature; it is not preſently, as the Choler, caſt into the ſink, but is further Cooked in the Spleen, and being exalted goes into a Ferment; which being laſtly committed to the blood, promotes its motion and Volatiliſation: Wherefore, as ſomething is drawn from the blood, entring the Spleen by the Arteries, to wit, the Crude Juice of Melancholly; ſo ſomething is continually added to the ſame, flowing back through the Veins, to wit, the ſame Juice concocted and exalted into the Nature of a Ferment: Even as Chymiſts, in Diſtilling, that the Liquor may be made better, ſeparate the ſubtile and ſpirituous parts, from the *Caput Mortuum*, and then pour them on it again; and this work they ſo often repeat, till the *Caput Mortuum*, or dead Head, is by frequent Diſtillation Volatilized, and the Liquor rightly exalted, even in all its Particles. That this is the uſe of the Spleen, is a ſign,

for

for that this inward being ill affected, the blood either ferments too much, as in the Scorbutick and Hypocondriack Diſtempers; or if the Spleen be Obſtructed, or beſet with a Scirrhous Tumor, the blood is deſtitute of fit Fermentation, and cauſes the Dropſie, Cachexie or evil diſpoſition of the Body, or the Tympany.

As we aſſert, the Earth and muddy part of the blood, which conſiſts chiefly of Earth and fixed Salt, being ſeparated in the Spleen, to paſs there into a Ferment; ſo it ſeems not improbable, that alſo the Aduſt, or as it were the fiery part of the blood, to wit, the Yellow Bile, which conſiſts chiefly of Salt and Sulphur, being ſeparated in the Liver, and from thence tranſmitted to the inteſtines, ſerves for ſome uſe of Fermentation. For this being mixed with the Chyme or Juice, fallen from the Ventricle to the Inteſtines, makes it there to grow hot and ſwell up; whereby both the Elementary Particles are more overcome, and by reaſon of the Rarification or ſwelling up, the purer part is wrung forth into the Milky Veſſels, for the Nutritious Juice.

We are not only born and nouriſhed by the means of Ferments; but we alſo Dye: Every Diſeaſe acts its Tragedies by the ſtrength of ſome Ferment. For either the Sulphureous and Spirituous part of the blood, being too much carried forth, boyls up immoderately in the Veſſels, like Wine growing hot, and from thence Feavers of a divers kind and nature are enkindled: or ſometimes the Saline part of the blood, being too much carried forth, ſuffers a flux; and from thence it being made acid, auſtere, and ſometimes ſharp, is apt for various Coagulations; from which the Scurvy, Dropſie, Stone, Leproſie, and very many Chronical Diſeaſes ariſe.

Yea we alſo endeavour the Cure of Diſeaſes by the help of Fermentation: For to the preſerving or recovering the Health of man, the buſineſs of a Phyſician and a Vintner is almoſt the ſame: the blood and humours even as Wine, ought to be kept in an equal temper and motion of Fermentation; wherefore when the blood grows too hot, even as Wine, it is uſual to empty ſome out of the Veſſels, and to allay its Fervor with temperate things. If any extraneous or heterogeneous thing is mixed with it, unleſs growing hot of its own accord, it drives it forth of doors; Purging, Vomiting, and Sweating Medicines by ſhaking and fuſing the blood and humours, promote its ſecluſion: when that the blood is depauperated, and grows leſs hot than it ſhould do, Cardiacks, Digeſtives, and eſpecialy Chalybeats or ſteeled Medicines reſtore its vigor and Fermentation: no otherwiſe than Wines growing ſowr, or degenerating into a deadneſs or want of ſtrength, are mixed with more rich Lees, whereby they may Purge or grow turgid anew. I could eaſily unfold the Curatory intentions, as alſo the effects and operations of every Medicine, according to the Doctrine of Fermentation; but I deſign a particular Meditation for this thing: for the perfecting of which ſerious work, God willing, I have determined to add to the buſineſs of Medicine, as I hope, ſomething not unprofitable.

Having thus far wandered in the ſpacious field of Nature, we have beheld all things full of Fermentation; not only in the diſtinct Provinces of Minerals, Vegetables and Animals, do we diſcern the motions and effects of this, but alſo the whole Sublunary World, ſeems as if one and the ſame ſubſtance were planted, and very pregnant through the whole with Fermentative Particles; which in every Region and Corner of it, as little Emmits in a Mole-hill, are buſied in perpetual motion and agitation; they fly about here and there; ſometimes upwards, ſometimes downward they are hurried, they variouſly meet one another, aſſociate themſelves, and again depart aſunder; with a continual Viciſſitude they enter into divers Marriages, and ſuffer Divorces, on which the beginnings, the death, and tranſmutations of things depend. Theſe little Bodies do not only very much abound in the boſom of the Earth, or in the midſt of the waters, but they are eſpecially diffuſed the whole Atmoſphear of the Air in thick heaps. It is ſufficient that I have noted in this place, ſome examples in a word: I have not determined a more full ſpeculation of them here. It is time that we proceed from Phyſical things, to the works of Art.

CHAP. VI.

Of Fermentation, as it is performed in Artificial things.

IN the works of Art, ſo various and manifold proviſion of Fermentation is perceived, that it is altogether impoſſible to enumerate their ſeveral Species; or to reduce the divers inſtances of this to certain Claſſes or Heads of diſtribution. Making uſe of the third of the following method, we will ſubjoyn ſome examples, (which have happened to our obſervation) by whoſe rule, many others may be laid open.

Con-

Concerning Fermentation, which is made in the Subjects, made by hand, or humane induſtry, theſe three things are chiefly to be conſidered,

Firſt, of what Nature and Compoſition Bodies are, that are moſt fit for Fermentation, and which are leſs convenient for it.

Secondly, What things are requiſite about Fermentation, to wit, what are wont to promote, or alſo to hinder its motion in every Subject.

Thirdly, How manifold the motion of Fermentation is, and the end of it; alſo what are the effects and alterations which follow it.

As to the firſt, That all Bodies, (when tending to perfection) may truely Ferment, they are required,

In the firſt place, That there be ſome parts looſe and disjoyned; otherwiſe the Fermentative Particles will not be ſtretched forth, or move from place to place: Wherefore in the more hard compact things, or in viſcous things, or too much boyled, or evaporated to a ſpiſſitude or dryneſs, Fermentation does not ſucceed. What are Liquid, as Wine, Beer, the Juices of Fruits and Herbs, eaſily and quickly ſwell up; next to theſe what are ſoft, tho they are of a thicker Conſiſtency, as Bread, and moſt Eatable things, and Medicinal Compoſitions.

Secondly, It is required that there be an Heterogeneity of parts, or a confuſion of all the Principles together; to wit, that ſome Particles do oppoſe others, and ſtir them into motion. For the more ſimple Bodies, in which one, or at moſt two Elements only are ſtrong, with a very ſmall proportion of the reſt, are unapt to Ferment: becauſe like Particles, or Symbolical Elements, lye benummed and quiet. But between the unlike, there ariſes preſently a ſtrife for domination, and ſome provoke others into motion.

Thirdly, There is a third condition, that there be neither too much Crudity, nor Maturity of parts, in the Body Fermenting. In the former, the active and ſubtil Particles are not eaſily extricated from the more thick, nor are brought into motion; as it appears in Juices, which are preſſed forth from unripe fruit; alſo in Beer which is made of Barly or Mault, not come forth or germinated. In the latter the Particles being made too volatile, are not contained in the bond of the mixture, but preſently evaporate, and diſpoſe their Subjects to Putrefaction. Wherefore, Juice expreſſed from Summer fruits, or others too ripe, will not eaſily paſs into Wine, but it will quickly Corrupt. And for this reaſon, extravaſated blood, milk and urine, do not Ferment, but quickly putrifie.

As to the ſecond thing propoſed, there are many wayes by which Fermentation is either promoted or hindred. The firſt and chiefeſt, is the adding of a certain Ferment to the body Fermenting; the Particles of which, when being firſt placed in vigor and motion, may raiſe up the others, idle and ſluggiſh, in the to-be-fermented Maſs, and may drive them into motion. But there is a twofold Ferment; either abſolute, which is the ſame kind of Body, in which the active Particles, being altogether placed in their vigor, are notable in motion, and ſo whilſt they are committed to the Subject in Fermenting, ſnatch with them into motion other Particles of every kind, before ſluggiſh: by this means Barm or Yeſt, beaten Eggs, and ſuch like, ſtir up a Fermentation almoſt in every thing. Or the Ferment is reſpective, to wit, which conſiſts of Particles, very much of one kind, which meeting other of another kind, in the Maſs to be Fermented, grow hot with them, and ſo produce in the mixture a turgency or riſing up of all the parts together. After this manner Saline Particles having gotten a Flux, grow very hot, with other Salines, either fixed or alchaliſate; as appears when acetous Liquors are poured on Corrals, Harts-Horn, ſhells of Fiſhes; alſo when the Spirit of Vitriol, and the Salt of Tartar, are put together, a great ebullition is excited.

There are ſome accidents and external circumſtances, which variouſly conduce, either to the provoking or hindring the motion of Fermentation; of which ſort, are chiefly the condition of the Ambient Air, the placing or laying up of the Body Fermenting, and the means of conſerving it.

The Southern Air (in which hot and humid Particles every where abound, which alſo eaſily entring any Bodies, obtain the force and place of a Ferment) impreſſes a notable motion of Fermentation in very many things: Wherefore in drinkable Liquors, it doth not only raiſe up at firſt, the force of effervescency or growing hot, but alſo for a long while after induces new ſwellings up in them being Fermented. On the contrary, the Cold and Northern Air, binds up, and very much faſtens Bodies; and in very many things hinders the fuſions, and flowings of the Elements, and oftentimes either hinders Fermentation from being ſtirred up, or reſtrains it being begun. Alſo the hot Summer Air, becauſe it too much moves the active Principles, drives away the Spirits and ſubtile parts, exalts the Saline, and Sulphureous into a Flux, and ſo perverts their equal motion; and either the Sulphur or Salt being too much carried forth, it eaſily brings to Bodies a rancidneſs or putrefaction, or a mouldineſs; which nothing favours the buſineſs of Fermentation.

It is a vulgar opinion, that ſome ſelect times of the year, to wit, thoſe in which the Vegetables of every Kind flower, cauſe anew the motion of Fermentation in the Juices, and other things,

things prepared of them, after they had fermented a long time before; ſo that Beer, when the Barly, and Wines, in the time that the Vine flowers, conceive riſings up, or new Fermentations: They ſay alſo, that Bread and Flowr, when the Wheat is in Flower, is wont to become ſooner muſty and mouldy; alſo that ſpots or ſtains of the Juices of Fruits, as the Mulberry, Blackberry, Rasberry, and ſuch like, being in Cloaths, are wont to be gotten forth again at that time when thoſe Fruits are ripe. Concerning theſe things, I ingenuouſly confeſs, that I have not made trial of them, by my own proper obſervation, ſo as to dare to affirm it for truth in every part; I will therefore lightly paſs them over, for it would both grieve and ſhame me (leſt I ſhould relate falſe things) to Philoſophize concerning doubtful things.

Concerning the laying up of the fermenting Body, theſe things are chiefly to be obſerved. When things firſt begin to Ferment, that they are not to be ſhut up in too cloſe Veſſels, neither while the Liquors are hot, are they to be put into Bottles or Casks; for the Particles at firſt boiling up, and as it were rarified, deſire a very large ſpace; wherefore the Fermentation of Wine or Beer is begun in open large Veſſels, but when they grow leſs hot, thoſe kind of Liquors, leſt the Particles being ſet and moved into motion too much, ſhould fly away from the Subject, they are kept beſt either in a cold Cellar, or cloſe Veſſels. In the preparation of Vinegar, we obſerve the contrary; to wit, it is wont to be placed in a hot place near the Chimney or Oven, or expoſed to the Suns-beams; to the end that the Vinous Spirit being depreſſed, the Saline part might be exalted into a Flux, and ſo might give a ſharpneſs to the Liquor. There is another Obſervation, that Liquors do ferment better in wooden Veſſels, than in Glaſs or Stone: for by long infuſion, ſome Saline little Bodies are got forth of the Wood, eſpecially the Oaken, which promote Fermentation.

As to the third thing propoſed concerning this thing, although to ſpeak properly, the motion of Fermentation is only a carrying forth of the Principles confuſed together, from a ſtate of Crudity towards Maturity; and the end of it is a tendency to the Perfection of every thing; yet Uſe or Cuſtom hath obtained, that this Word is attributed to very many other motions of Natural things, and includes other Ends and Effects, far different. Therefore when the Fermentative Particles in any Body, are greatly in motion, the Alterations which follow thereupon, may be in ſome reſpect referred to theſe three Claſſes.

Firſt, It either reſpects the Exaltation and Perfection of the Parts of the ſame Body; or the Reſolution and Corruption of them.

Secondly, Or the Diſſolution of the Parts of another Body, is intended; or the Præcipitation of thoſe looſned.

Thirdly, By the motion and action of theſe kind of Principles, a Coagulation, and alſo a Congelation, now of the ſame Parts, now of different Bodies, are induced. It remains, that we briefly run through every one of theſe Species of Natural Motions, and Ways or Manners of Fermentation.

CHAP. VII.

Of Fermentation, as it is ſeen in the Exaltation of Bodies, and Tendency to Perfection.

THE Exaltation of the Parts, is perceived beſt in Works, or in all things appointed for Human Uſe, foraſmuch as they get a greater Perfection and Vigor, by Fermentation; as chiefly Aliments and Medecines do; In many of theſe, we endeavour to carry forth the Spirituous Particles above the reſt, and ſo to procure in the mixture, a grateful ſweet taſte, and other agreeable Qualities; as we may obſerve in Bread, Beer, Wine, Cider, and many others: But in ſome, we ſtrive to exalt the Saline part, the Spirit being ſomewhat depreſſed; as in Vinegar, Meath, Broths; alſo in Sauce, Pickle, or in Preſerved things, which are made of Salt and ſharp Liquors. We rarely on purpoſe carry forth the Sulphureous part above the reſt. for from thence a ſtinking ſmell, and ungrateful rammiſhneſs are wont to happen to eatable things. Among Food ſet apart for mans Uſe, Bread, Beer, Wine and Cider have the firſt place; which owe moſtly, whatever they have of Virtue or Strength, to Fermentation.

Concerning the making of Bread, theſe things are chiefly to be obſerved: The Meal of Wheat or Barly, or of any other Grain, being kneaded with common water, is reduced to a Maſs, to be afterwards baked in an Oven. If there be nothing elſe added to this, it becomes forthwith heavy, and ponderous like Clay, clammy, and of an ingrateful taſte, and of difficult digeſtion; but if in the kneading it, there be added a Ferment, the Maſs preſently grows hot, the Bulk ſwells, and afterwards being baked, it is made light, ſpongy, of good digeſtion, and grate-

ful

ful to the Taſte. If you deſire to know the reaſon of the difference, it is this; The meat of the Grain is imbued with a moderate proportion of Spirits, alſo of Salt and Sulphur; but the Particles of theſe are overwhelmed in the Maſs with a viſcous humidity, being kneaded with water; ſo that they move not themſelves mutually, nor are in motion; wherefore in the baking, ſome ſuperfluous humidity evaporates; what remains, is cleaving, viſcous, and becomes preſſed cloſe like Clay, and ponderous. But when a Ferment is mingled with the Mealy Maſs, the active Particles of the Ferment being firſt ſtirr'd up into motion, take hold of their Companions in the Mealy Maſs, and carry them with them into motion. By this means, whilſt ſome move others, they ſhortly are all ſtirred up into Fermentation; tumultuating here and there, they compaſs and run through the whole Paſte or Dough, they ſubtiliſe and attenuate the clammy and terrene parts, and they lift up the maſs, with the motion, and make it hollow, with little holes; which yet in the mean time, leſt it become too ſpongy, and whereby the parts made hollow, and attenuated, might more exactly be mixed, it is wrought with long kneading, then afterwards, before the Fermentation ceaſes, and before the hollowed parts ſink cloſe down, it is baked in the Oven. In the baking, the ſuperfluous moiſture evaporates, and moreover, very many Particles of Spirit, Salt, and Sulphur, fly away; wherefore, the maſs becomes lighter, and leſs ponderous, in the mean time, thoſe which remain in the Bread, being much exalted, and brought to maturity, cauſe in it a laudable conſiſtency, with a grateful ſmell, and taſt.

The Ferment commonly uſed, is a portion of the Mealy Maſs, and unbaked, which is kept, being imbued with Salt, to a ſowrueſs (it is called in *Freneh*, *Levain*, becauſe it lifts up the Maſs) or the flowring of Beer, or Ale, called Yeſt or Barm; or for want of theſe the lees or dregs of Beer, or beaten Eggs, are made uſe of. In the mealy Ferment, the Saline Particles having gotten a flux, do chiefly predominate; as alſo in the fæces of Beer: wherefore the Bread Fermented by theſe, is made harſh and ſomewhat ſowr: In the mean time, Yeſt being very big with Spirit, Ferments the Bread more potently, and brings to the Maſs lightneſs, and a very grateful ſweetneſs. Beaten Eggs abound with Spirit and a Volatile Salt, and do yet more cauſe the Bread to Ferment, and render it more Spongy: without doubt there may be other kinds of Ferments uſed; for whatever are big and turgid with Spirit, or abound with Salt carried out to a Flux, ſeem to be fit enough for this uſe.

Sometimes the mealy Maſs is kneaded with Sulphureous matter, as Butter, Sewet, Fat, or ſuch like, which being baked in an Oven, while it is hot, it is ſeen to be light and ſpongy, (to wit, while the Sulphureous Particles are kept in motion by the heat contracted in the Oven) afterwards, when this Maſs grows cold, it becomes heavy, weighty, and very cloſe: to wit, the aſcititious heat being exhaled, the Sulphureous Particles, before carried forth, at length ſink down; and when the Particles of the reſt, not being excited into motion, the Maſs therefore becomes as it were Infermentated: For in theſe kind of Subjects the Sulphureous Particles, becauſe they are very viſcous, hinder the motion of the reſt, nor can they themſelves perſiſt in motion, longer than they are forced, by the actual heat.

Bread is ſometimes made of the flower of Wheat, or Barly, that is Germinated or Maulted, which without any Ferment added to it, becomes ſo exceeding hot, that it cannot be contained in a compacted maſs, but that in the baking it ſpreads abroad: the reaſon of which is, in ſuch Flower, by the Maulting it, the active Principles are before placed in their vigour, and exaltation; wherefore in the kneaded Maſs, when they are urged, by the heat of the Oven, they run forth inordinately, and force the more thick parts, hindring them, and as it were fling them down head-long. We have ſaid enough of making Bread; we will now paſs to Beer.

Beer is made of Mault or Barly, germinated and dryed, which is performed after this manner: Firſt, the Barly is put into common water for three days, that it may intumifie or ſwell, then (the water being let out from it) it is flung in a heap upon a dry floor, moving it twice or thrice a day, leſt it grow too hot, until it begins to germinate, or bud forth, or put out little ſhoots of Roots. Afterwards, by frequent caſting it about, it is hindred from germinating or ſpringing forth any farther, and laſtly, being lay'd upon a Kiln, it is made dry by roſting it; by this means, it yields a meat wonderfully ſweet.

The reaſon of this kind of proceſs is this; the Barly is permitted to ſpring forth, that its active Principles might be brought or ſet into their ſtrength, or exaltation: for when it germinates, the Spirit, Salt, and Sulphur, at firſt aſleep, and ſluggiſh, do ſwell up or grow big together, and their ſluggiſhneſs being caſt off, they are prepared to exerciſe their powers. The other preparations, hinder the Barly from germinating further, leſt that its Principles being very much looſned, ſhould exhale too much, and fly away from the Subject. The Meal of the Barly thus prepared grows ſweet, becauſe the active Principles are ſet in exaltation like Fruit brought to a maturity: wherefore alſo the Liquor impregnated with this Meal, grows very turgid or big with Spirituous and Fermentative Particles; when the ſimple decoction of Barly, ſcarce Ferments at all, nor is kept long, but that it becomes muſty, and inſipid.

But Beer is made after this manner; upon the Meal of the Barly, prepared as aboveſaid, boiled water is poured, and is ſuffered to be macerated, or maſhed, for ſome hours, that it may be

ſufficiently impregnated with the active Particles of the germinating Barly, now placed in their vigour: This Liquor being ſatisfied or filled, is drawn off clear from its ſetling, and is laſtly boyled, that it might get a ſomething more thick conſiſtency, and be able to be kept the longer: Then, when it is ſomewhat cold, it is fermented, a ferment, or the flowring of Beer or Yeſt, being put thereto, and ſo tunn'd up in a Barrel. Concerning its Fermentation, theſe things are eſpecially worthy of obſervation.

If it macerate with, or ſtand too long on, the Maulted Meal, the Liquor becomes thick and clammy; and afterwards will hardly ferment or work at all: the reaſon of this is, becauſe the active Principles, in this work, are of a prompt motion, and move together with them, the earthy Particles; with which, if by a long ſtay, the paſſages and pores of the Liquor are filled; being too full, they are wholly obſtructed, and as the contents in the Stomach, ſtuffed to a ſurfeit, ſcarcely ferment at all.

If too hot, or too cold, the Liquor be put into the Barrel; as in the great heat of the Summer, or the cold in the Winter, Fermentation doth not rightly ſucceed: for by too much heat, the Particles are diſſipated one from another, that they cannot, mutually take hold of one another, and ſo work; by too much cold, they are bound up and fixed, that they ſcarce enter into motion, neither perform it ſtrongly.

When the Liquor of the Beer ferments in the Vat, the active Principles do on every ſide explicate themſelves, they precipitate in the bottom the more thick, and Earthy, being partly driven as it were into flight, and partly ſticking to them, they lead them as it were Captive to the top, and there make hollow bubbles continually growing up, and bring them as it were to ſervitude. After a due Fermentation, the whole ſpace of the Liquor is rendered clear and without dregs, in which the Spirits with a little Salt and Sulphur, do abound; in the mean time, in the ſettlement or dregs, a little of Spirit and Sulphur, with a greater plenty of Salt and Earth remains. So long as theſe ſhall be in their places, the Liquor will be clear, ſweet, and Spirituous, but if long kept, or not ſhut up cloſely in a Barrel, great part of the Spirits will fly away: in the mean time, by the defect of theſe, the Saline Particles being exalted, and having gotten a Flux, impregnate the whole Liquor, and make it ſowr; for when Beer, as alſo Wine, goes into Vinegar, it doth not happen becauſe they are wholly deprived of Spirits (for ſo they would degenerate into a taſtleſs thing) but becauſe the Tartarous or Saline parts, are carried forth to a Flux, and infect the Liquor with their ſharpneſs; in the mean time, the Spirits being leſs in power, are depreſſed, that they cannot reſiſt them. Very hot Weather, Thunder, the noiſe of great Guns, or the tunning it in the open Air, ſuddenly makes Beer grow ſowr, for by theſe means the Spirits being diſturbed in their equal motion, are diſſipated; and in the mean time, the Saline or Tartarous parts, being before ſeparated, and depreſſed, are moved, and carried forth into a Flux.

Indeed it plainly appears, that the Spirituous parts in Vinegar, are not wholly deſtroyed, but ſuppreſſed only whilſt the Saline are placed in a Flux; becauſe from Vinegar, may be Diſtilled, a Liquor exceeding hot and burning, like the Spirit of Wine, after this manner: With the diſtilled Vinegar, a Salt is extracted from Minium, or Lead Calcined, of which you have plenty, and ſhall diſtil it in a Retort, the Vinous and burning Spirit is driven into the Receiver; the reaſon of which is, becauſe when the Saline Particles of the Vinegar are united with the Salt of the Lead, the Vinous Spirits yet remaining are then freed; and having obtained their own right, they are urged from their lurking places by the heat of the fire: but thoſe Spirits are not produced from the Lead, becauſe if you give thereto a more vehement fire, the Salt of the Lead, will be melted into a Metal.

But we will return to Beer, from whence we have digreſſed; to which, how great a perfection happens, by Fermentation, appears by this Experiment: If you take Beer new made, not yet purged by Fermentation, and place it to be Diſtilled in a Bladder or Cucurbit, only a vapid or taſtleſs water aſcends, without any Spirits, and ſtrength at all: but if you proceed after the ſame manner with Beer truly fermented, you will have a hot water, and highly Spirituous. And this takes away the objection of ſome, who ſay, that water being even impregnated with the Meal of Mault, ſhould not be any more boiled, leſt the Spirits ſhould exhale; becauſe the Spirits, before Fermentation, are ſo obvolved with the more thick Particles of the reſt, that they cannot break forth from the Concrete.

The more the Beer is impregnated by the Mault, the ſtronger it is, keeps the longer without ſowring; which is helpt if Hops be boiled therein, from which at firſt it grows bitter, but afterwards recovers a grateful ſweetneſs; the reaſon of this is, becauſe the pores of Liquor, which are empty of the Particles of the Meal, when they are poſſeſſed by thoſe of the Hops, the conſiſtency is made more compact, and is more full of fermentative Particles; wherefore there is not quickly given any room for the flux of the Salt. But that the Liquor being at firſt bitter, afterwards grows ſweet, happens for this reaſon; becauſe the Spirituous and Sulphureous parts, ſupplied by the meal of the Mault, come not ſo ſoon to maturity, becauſe of the others mixed with them from the Hops being boiled therein: but when this happens, that they grow to maturity, they eaſily excel all the others, and impart a ſweetneſs to the whole. Not only Hops being

being boiled in Beer, keep it long from ſowring, but alſo many other bitter, or ſharp things, do the ſame: for theſe, foraſmuch as they exceed in a Volatile Salt, hinder the flowings of other Salt; wherefore, ſome are wont to put into the Barrel, a piece of Saſſafraſs Wood, the tops of Wormwood, Broom, the Firr-Tree, the rinds of Oringes, alſo Spices in a ſmall quantity; by which means, the Drink, tho of a ſmaller ſubſtance, is kept a long while from ſowring. Thus much concerning the Preparation of Beer, on the conſideration of which, (as alſo of Bread) we have ſtayed long, becauſe the Word Fermentation is chiefly due to theſe. Let us paſs next to Wines.

Excepting the Blood of Animals, there are no Liquors that grow hot, like Wines; there is found in none a greater plenty of Spirits, Salt, and Sulphur, or a more remarkable turgeſcency, or ſwelling up. The Fermentation of Wines, and the handling of them fermenting, are wont to be taught among the Vintners or Wine-Coopers, as a Secret only to their Apprentices, or the Adepti of their Art. Among them there is delivered a certain Phyſical Science, or Method of Medicine, by which means, the impurities of Wines are purged forth, their heats attempered, or alſo their defect, or ſickneſs may be healed. There are many ways to be uſed, beſides that of Sophiſticating, as a Secret, by which depauperated and taſtleſs Wines are ſold for ſound and rich. But as to our Propoſition, that the Doctrine of Fermentation might be illuſtrated, theſe three things ought chiefly to be conſidered, concerning Wines: Firſt, Their defæcation or cleaning, and their going into parts. Secondly, Their immoderate effervescency or growing hot, from what cauſes it is wont to be ſtirred up, and by what means to be ſuppreſſed. Thirdly, The declination of them, when they grow worſe: and by what remedies they are kept that they do not quickly paſs into a taſtleſneſs or Vinegar.

1. As to Firſt, That Fermentation may begin in the Muſt, there is not (as in Beer) required, the putting to any ferment, for the Juice being expreſſed from the Grapes, doth ſo greatly ſwell up with active Particles or Principles, that it preſently of its own accord, grows remarkably hot: but it is a uſual thing in ſome Regions, when the Grapes are trod, to beſprinkle them with Quick Lime, by the provoking of which, as a ferment, the Liquor preſſed forth, grows more fervent, and is ſooner purged. The Muſt or new Wine, is at firſt put into open Tubs, for that they cannot be contained in cloſe Veſſels, for their great heat or working, which ſo boyls up, that water over a fire grows not more hot: when the Wine is a little cooler, it is put into more cloſe Veſſels, in which it is further purged by fermenting. In the purifying, the Spirituous and Subtile Particles greatly ſhake the more thick dregs, and diſmiſs them from themſelves on every ſide, that the Maſs of the Vinous Liquor, being made free from the mixture of the dregs, is rendred clear and without dregs. The Fæces or Lees of the Wine conſiſt of Salt and Sulphur, with a little Spirit and plenty of Earth; which whilſt the Wines grow hot, being ſeparated by degrees, either by Coagulating themſelves mutually, are affixed to the ſides of the Veſſels under the Species of Tartar, or like Lees or Mother, ſettle to the bottom. In the mean time the Liquor ſwimming over them, is very clear and exceeding Spirituous.

Sometimes the defæcation or clearing of Wines is hardly brought about, as a Vinous Liquor is not eaſily freed from the mixture of Tartar: wherefore Vintners are wont to put to the Wines ſome Bodies that either clear them, or precipitate them, ſo as the Earthy matter ſwimming in them, may ſooner ſettle to the bottom: The things which ſo clarifie Wines are of two ſorts: for they have either viſcous parts, as Glew, the Whites of Eggs, and ſuch like, which ſtick cloſe to the fæculencies of the Wine with laying faſt hold on them, and carry them with themſelves towards the bottom: Or elſe they abound in a precipitatory ſtrength, which while they enter into the pores of the Liquor, thruſt forth the more thick Particles from thence, and ſtrike them down to the bottom; as are the duſt of Alabaſter, Calcined Flints, and ſuch like.

2. Wines tho at firſt they were well cleared, yet afterwards they conceive immoderate effervescencies, ſo that the Tartar, being ſtirred up from the bottom, it at length mingled with them; alſo the Spirits being looſened, now the Sulphureous Particles, now the Saline being too much carried forth, render the Wines unſavory, clammy or ſowr. We will conſider theſe things, from what Cauſes they come to be ſo, and by what Means they are Cured.

Wines very often contract heats, when they are full of Tartar or too rich Lees: For Tartar or Lees, tho ſeparated from the Liquor of the Wine, and depreſſed to the bottom of the Veſſel, yet for that they conſiſt of plenty of Salt and Sulphur, they ſtill ſend from themſelves fermentative Particles, by the inſpiration of which the Wine is kept in an equal motion of Fermentation: and as the Wines are leaſurely ripened, ſo the Salt and Sulphur which lurk in the Tartar, are by little and little exalted; until at length, being carried forth to a flux, they infect the Vinous Liquor, with a troubled feces or dregs, and compel it to grow immoderately hot, and to boyl up. Againſt theſe too great heats of Wines, there is a neceſſity, that they be preſently drawn off or rack'd, from this too rich Lees, and put into another Veſſel, or elſe it comes to paſs, by reaſon of its too great diſturbance, the Sulphur being very much exalted, that they become unſavory and ropy; or the Spirit being loſt, and the Salt carried forth to a flux, they contract a ſowrneſs, and turn to Vinegar.

Neither doth Wine grow more hot than it ſhould do, only from Tartar, or too rich Lees, but by too great agitation, immoderate heat, or by an extraneous or ſtrange Body put to it, and not miſcible, or that cannot mingle with it: for by theſe and other ways, the Sulphureous part of the Wine grows hot, and from thence conceives a fervour, and undue boyling up; for the ſetling of which, beſides the racking or drawing it off, from one Veſſel into another, they uſe to pour plenty of Milk, into the Pipe or Barrel, by whoſe mixture the heats and tumults of the Wines are preſently appeaſed; but as by this means the Spirits of the Wine are very much overcome, it cannot keep long, but ſoon after degenerates to Vinegar, or without taſt; therefore the Vintners are neceſſitated to ſell preſently the Wines mended by this Artifice, and very ſuddenly to draw them off.

Theſe kind of heats of Wines, tho' they be timely appeaſed, before they wholly ſpoyl the Wines, yet they leave ſome viciouſneſs, by which the Vinous Liquor is altered from its due colour and conſiſtency, and is made leſs grateful to the Palat: for Wines made hot, oftentimes become of a more deep colour, *viz.* they degenerate from a watery and clear colour, to a Citron or Red, and give to the taſt a rankneſs; all which indeed proceed, from the Sulphur being too much carried forth and exalted: For theſe kind of diſtempers of Wines, they proceed after this manner; for the mending the colour, oftentimes ſimple Milk, or boiled with Glew or fine Flowr, is poured into the Hogſhead or Pipe; for theſe procure a certain ſeparation of the exalted Sulphur, and with its whiteneſs give a clearneſs, or reſtore the colour to a brightneſs. Mucilaginous, clammy, or ropy Wines, are amended by the infuſion of burnt Alum, quick Lime, Gypſum, or Plaiſter of Walls, Salt and the like; for theſe cauſe a new Fermentation, that the more thick Particles are thruſt forth from the reſt, and precipitated towards the bottom. The unſavourineſs is helped by the ſame means.

3. As to the the third Propoſition; Wines are depauperated or made poor, when by a long effervescency the Spirit and more pure Sulphur, being exhaled, the Saline Particles begin to be exalted: in this caſe their languiſhing ſtrength is ſuſtained with certain Remedies, as it were Cordials.

As the Spirit and Sulphur being too much carried forth, and exalted, is cured by the drawing off the Wines from the rich Lees; ſo the ſame being depreſſed, the Remedy is, that they be put to a more rich Tartar or Lees: wherefore the Vintners are wont to pour the depauperated Wines, deſtitute of plenty of Spirits and Sulphur, and which begin to grow ſowr, by reaſon of the Salts being carried forth to ſound and freſh Lees or Tartar; that they might, as it were, anew inſpired with Spirit and Sulphur, ferment and recover new ſtrength and vigor; beſides they make Syrups of generous and rich Wines, with Sugar and Spices, which they pour among the ſtale and deadiſh Wines. Further, for Wines turning to Vinegar, they are ſaid to adminiſter profitably, ſome other Remedies. *Grataroius* praiſes, with many more, Lard and Swines fleſh ſalted, wrapt in Linnen, and put into the Cask: and truly it is probable, that the Sulphureous odour of this doth reſtrain the flux of the ſowring ſalt; for this end the ſame Author commends Leek-ſeed, Pine-nuts, blanched Wheat, boiled Wine, Aſhes, the ſhavings of Willow, and many others; for the ſalt readily acts on theſe kind of ſubjects, and ſpends its force; even as Virgins ſick of the Green-ſickneſs, deſire greedily to eat ſuch like abſurd things, that may ſatisfie the extraneous, and for the moſt part ſowriſh ferment of the Ventricle, but very hurtful to themſelves. There remains another kind of Cure, whereby ſmall Wines almoſt corrupted, and growing vapid or ſmatchleſs, recover new vigor for a time, to wit, a portion of Rheniſh Wine, or others, very fermentable, is laid up, and hindred from fermenting, from whence it is made a perpetual Muſt (commonly called Stum) if a little of this Liquor be poured into a Cask of ſtale Wine, and jogged together, it gives a freſh, and new Fermentation to the whole: ſo that that Wine will froth and boyl, and ſhut in a Glaſs, will leap forth; but the drink mended by this Artifice, is accounted very unwholſom, for that it is apt to ſtir up an immoderate Fermentation in our blood: wherefore it is prohibited by Edict, that the Wine-Coopers or Vintners make not uſe of this kind of Sophiſtication.

It is a uſual thing alſo, to ſtop up cloſe, in Stone or Glaſs Bottles, for a time, ſmall Wines, and new Ale or Beer, which being afterwards opened, the Liquor ferments ſo impetuouſly, that being almoſt all rarified into froth, it flies forth of the Bottles: which beſides contracts ſuch an acrimony or ſharp cutting, that it can ſcarce be ſwallowed: The reaſon of which (as it ſeems) is this: The turgency or ſwelling up, and the notable acetoſity, ſharpneſs, or quickneſs of theſe kind of Liquors, proceeds chiefly from the Salt being exalted, and having gotten a Flux; for when as the Liquor, being full of much Tartar, and little Spirit, is ſhut up cloſe in a Veſſel, all the Particles together are forced to be fermented, and when they cannot be ſeparated, and fly away from one another, they do the more trouble one another, and break themſelves into ſmall bits; that by this means the bond of the mixture may be wholly broken; but the little bodies looſened one from another, and as it were freed by reaſon of the cloſeneſs of the Veſſel, are forced together: wherefore when the Veſſel is opened, all the Particles at once being ready for flight, like Air ſuddenly rarified, break forth with noiſe and tumult: and becauſe the

the Saline parts having gotten a Flux, by reaſon of the plenty of Tartar, are ſtroliger than the Spirit and Sulphur, from thence the notable cutting ſharpneſs is cauſed in the Liquor.

Cyder comes next to the Nature of Wine, to wit, of the ſmaller ſort, which kind of Liquor, is only the Juice preſſed from Apples, and brought to maturity by Fermentation: concerning this kind of Drink, it is worth obſervation, that if it be made of Summer-Fruit, or too much ripened, it will not keep in ſtrength, but preſently degenerates into a deadneſs: but if it be prepared of very unripe, and ſowr Apples, it contracts a bitterneſs, for that the Spirits do not ſufficiently ariſe in this, but give place to the ſalt, having firſt gotten a flux: but in the other, they are not long enough retained, but wholly fly away, before the maſs of the Liquor attains to full Fermentation: but there are Fruits and Apples, exceeding fit for this buſineſs, which being indued with a more firm conſiſtency, are not quickly corrupted, neither do they attain their perfect maturity or ſoftneſs, but of a long time: The Juice of theſe wrung forth, and put into a Cask, does not grow hot, as Beer, with a great frothy head, but after the manner of Wines, with a noiſe, like a Pot boyling over the fire: whilſt fermenting after this manner, it is made clear, the more light Recrements are carried upwards, and remain in the ſuperficies, as the flowering: but the more thick parts and Tartarous ſettle plentifully in the bottom; but the more ſolid Cruſt, or Coagulated Tartar, is not fixed to the ſides of the Veſſel; which is a ſign Cyder is a more wholſom Drink, nor ſo infeſtous to the nervous ſtock, becauſe it abounds leſs with a ſharp ſalt than ſmall Wines. The Liquor ſwimming over theſe Fæces or Lees ſettling in the bottom, enjoys it as it were its food, and is kept by its inſpiration in ſtrength; from which, if it chance to be drawn forth, it quickly grows ſowr: for indeed this kind of Drink, is in great danger to be deſtroyed by the flux, or ſowrneſs of the ſalt: againſt this ill, to preſerve it, ſome are wont to caſt into the Cask Muſtard Seed bruiſed, or Muſtard Balls, for that the Volatile Salt of this hinders the flux of the acetous Salt, ſo that the Liquor thereby preſently grows clear, and keeps the longer: another kind of Remedy againſt the ſowrneſs of Cyder, is, that as ſoon as it begins to grow ſowr, it be drawn off from its Lees, and kept in cloſe ſtopped Bottles, with a little Sugar; for by this means it ferments anew, and becauſe, together with the flux of the ſalt, the ſpirits being carried forth, are detained from flight, a very grateful ſharpneſs is cauſed to the whole Liquor. Alſo, almoſt by the ſame preparation, and the like proceſs of Fermentation, a potable Liquor is made out of Pears, which is however above meaſure ſweet, and if plentifully drunk, renders the Belly looſe, as if they had taken Phyſick.

So much for Fermenting Liquors, whoſe vertue conſiſts in the Spirit being carried forth, and obtaining the height of perfection: there remains other Preparations, whoſe vigor is placed in the ſaline part being exalted, and having gotten a flux; among theſe, Vinegar is of chiefeſt note, the way of making of which, being wholly unlike the aforementioned, requires a method of Fermentation, very different from thoſe before deſcribed: For example, ſmall Wines, or more generous or ſtrong Beer, being put up into the Cask, are expoſed in the Summer-time, for a long while to the Suns Beams, or elſe in the Winter, they are kept near a Stove in ſome hot place; after this manner, whilſt ſome Spirits evaporate, the reſt being put under the yoak, the Saline parts are exalted and infect the whole Maſs of the Liquor with their ſharpneſs: but not only Wines long kept, or ſtale Beer, out of which the ſpirits of their own accord, begin to go away, but freſh Muſt, or new Beer, paſs after this manner into Vinegar; for the Country-women are wont to place without doors all the Summer, ſtrong Ale, and highly impregnated with Mault, in a Cask, by which means they make an exceeding biting and moſt penetrating Vinegar.

Yea after the ſame manner almoſt, our kind of Hydromels, Honied Drink, or Meath are wont to be prepared: to wit, they boyl ſixteen parts of Water with one part of Hony, to the conſumption of a third part, adding then ſome Spices, together with a ſharp ferment, they place the Cask and Liquor for many days in the Sun, and afterwards in a Wine-Cellar. It ſeems the Sunning of it is uſed, that thereby the Saline parts being brought towards a flux, might ſomewhat reſtrain the nauſeous ſweetneſs of the Hony: and by that means the ſweet being tempered with ſharpneſs, a moſt pleaſing taſt is afforded to this Drink.

By reaſon of the ſharpneſs ariſing from the flux of the Salt, alſo very many eatable things are wont to be prepared after various manners; hence the fleſh of living Creatures, and eſpecially of Fiſhes when they ſwell with too much Sulphur, are pickled with ſalt Brine or ſharp Liquors, that the Salt being brought forth, they may become more grateful to the ſtomach. It would be a tedious buſineſs to inſiſt here on particulars; but I will in this place deſcribe a certain noted kind of Oaten Broth, Grewel, or Flumery, which profitably nouriſhes Feveriſh, alſo Conſumptive and Hectick People.

This kind of Drink, that it may become gratefully ſowriſh, the Meal of Oats is put into common water for about three days, till it acquire a ſomewhat ſowr taſt: then, this infuſion is placed upon the fire, and with a Ladle is ſtirred about until it boyls, and when it riſes up ready to flow over the Veſſel, it muſt then be poured forth into a Platter, and preſently cooled; it

will

will appear like Gelly, and may be cut into bits; which if heated ſoon melts. In this preparation may be obſerved, that by a long infuſion of the Grain, the ſaline parts being brought forth, do get a flux; then theſe ſo impregnate the Liquor that the more thick Particles being by the heat brought into its pores and paſſages, they are ſo ſtrictly ſhut up, that they cannot eaſily ſink down, but that the whole mixture becomes like Gelly.

It would alſo be too great labour to heap together here, the various Condites and kinds of Pickles, for it would be to deſcribe under that rank the whole Art of Cooking and Diet. For in both the only aim is, that for healths ſake and for pleaſure, the active Particles in our food, may be placed in their vigor and exaltation; for ſo they greatly pleaſe the Palate, and by a more eaſie digeſtion go into nouriſhment: for this reaſon, not only Drinks, and Confections of Corn, and Herbs of a diverſe nature and kind are thought on; but alſo we variouſly prepare fleſh, both boiled and roſted, and add to them ſauces, that the Particles, now the Spiritous, now the Saline, being carried forth to a flux, might pleaſe the taſt, with a certain ſharpneſs. Thoſe which are of a more fixed nature, are brought to exaltation, by Sauces made of Sugar, Salt, or Pepper. They are wont to keep ſome fleſh almoſt to putrefaction, that by that means, the active Particles being placed in their ſtrength and motion, may become of a more grateful taſt. Here might be interwoven, a long diſcourſe concerning Medicinal Compoſitions, but becauſe this ſubject, deſerves a peculiar conſideration, I will ſay nothing more of it here. Let us next ſee by what motion of Fermentation and Habitude of Principles, Natural Bodies tend towards diſſolution; or what is the progreſs of every thing to Putrefaction and Corruption.

CHAP. VIII.

Of the Motion of Fermentation, which is obſerved in the Death, alſo in the Putrefaction and Corruption of Bodies.

NAtural Bodies in which Spirit, Salt, and Sulphur, are found in but a mean quantity, do not ſtay long in the ſame ſtate: for theſe active Principles are employed perpetually in motion: As ſoon as they come together, they tend from Crudity and Confuſion towards Perfection, for the ſake of which, when they have reach'd the height, they are able to come to, they are not quiet in this point; but from thence they make haſt towards the diſſolution of that thing. Thoſe which are more volatile do firſt of all break forth from the looſened bond of the mixture; then the reſt ſeparate into parts, until the form of the mixture wholly periſhes: The Spirit being carried forth to the top, flies away firſt with the water, and the more pure Sulphur, and by its expiration, diffuſes a very grateful odour; afterwards the more thick Sulphur, with the Salt, being looſened from the band wherewith they were tyed, and having gotten a flux, by degrees evaporate, and together diſperſe a very ſtinking ſmell: together with theſe, the watery parts flow forth, and the frame of the ſubject breaks, or falls down into Earth, or a *Caput Mortuum.*

This kind of proceſs may be obſerved both in natural things, and alſo in Subjects prepared by Art: Concerning Natural things, the disjunction of the Elements, and their ſeparation into parts, may be ſeen both in the death of living Bodies, or the extinction of life and vegetation; and alſo in the corruption of them being dead, and in their reduction to a rottenneſs.

As in Vegetables, the growth and maturity depend on the combination and mutual cleaving together of the Principles, ſo the decay and death depend on their going aſunder, and ſeparation, in Plants and Fruits; being by degrees exalted from a crude and ſowr Juice by Spirit and Sulphur, they come to maturity; to which a ſweet taſt and ſmell, and a pleaſant colour happen: then preſently the ſame matter, the Spirit and Sulphur, and the reſt of the Elements leiſurely flying away from the ſubject, is ſoon reduced to a filthineſs and rottenneſs: If after the ſubtil and more pure Particles of Spirits and Sulphur are flown away, there ſtill remain plenty of Earth and Salt, with ſome Sulphur, the matter does not putrifie, but grows dry with an hoarineſs: but if the thick Salt and Sulphur, having gotten a flux, break forth from the Subject, together with the reſt, the bond of the mixture being looſened, preſently the external humidity, poſſeſſes the ſpaces left by theſe, and the Body is reſolved into rottenneſs.

Alſo all Animals whatſoever, have ſet bounds of their growth and duration: For they aſcend from their beginning, by ſlow increaſe, to motion and ſenſation; then to the ſtrength and exaltation of Nature: in which point they ſtay not, but from thence, by equal ſteps, make haſt towards their fall.

If

If the cauſe of this kind of limitation be required, we ſay that Mother Nature hath placed in the primigenious ſeed of every thing, ſuch a ſtock of Spirit, Salt and Sulphur, which might ſuffice for the producing the utmoſt thrids or lineaments of Bodies: ſo that the growth and aſcent of the thing, to its height or *achme* is only an evolution, or unrowling of that radical matter, and protenſion or ſtretching it ſelf forth into a greater dimenſion; in the mean time the little ſpaces and vacuities, which are made by the protraction of this matter, are filled up by the active Particles, ſupplied by Nutrition, which alſo by a continual ſeries of motion are ripened, exhaled, and give place to others ſucceeding. As ſoon as this ſeminal matter is unfolded and exalted to the height, that it cannot be moved, or expanded further, the matter is then brought to the ſtate of its perfection: from thence ſome Particles of this Radical ſubſtance, together with the ſecondary ſupplied from the Nouriſhment, begin to evaporate; and others daily, and then others, being after this manner conſumed, both the ſolid parts, by degrees decreaſe in their ſubſtance, as alſo the Nutritious Juice and Blood, even decline for the worſe, till by a long waſting, the props of the Body, are made dry or withered, and the Blood ſo depauperated, that it will not ſuffice for ſuſtenance to the vital fire: juſt as it may be perceived in a Lamp, if the Oyl being continually conſumed, in its place be put Water, the Liquor is rendered poor, and diluted, that it is not able any longer, to cheriſh at all the flame of the Wick.

When the Life of Animals periſhes, (either it expires after the aforeſaid manner leiſurely, and like a Candle or Lamp is extinguiſhed, the Oyl or Tallow being conſumed; or it is choaked by a haſty death, being ſnatched away by Fate, or the violence of a Diſeaſe) preſently the Spirits, with Salt and Sulphur, flowing together in the blood; and alſo planted in every part, ceaſe from their regular motion, and are moved into confuſion: then they partly exhale from the pores, with the vaniſhing heat, and partly being ſhut up within in the Cavities, inordinately ferment, with the remaining Particles, and make a ſwelling up of the inwards, and of the whole Body. But afterwards the frame of the ſolid parts being by degrees looſened, and the Sulphureous Particles, together with the Saline, having gotten a Flux, begin to evaporate; from thence a ſtrong ſtink and corruption ariſe. The active Principles, breaking forth by heaps, do often mutually take hold of one another, and being combined in the ſuperficies of the Carcaſe, produce Worms: at length when they are wholly exhaled from the Subject, what remains falls into duſt.

It is a uſual thing for Worms to be generated in Vinegar when it is corrupted and loſt its ſtrength, which being exceeding ſmall; and ſomewhat long and ſmooth like Eels, ſwim in the Liquor, and may by the help of Glaſs be expoſed to our Eyes; theſe being ſeen, it is commonly ſaid, that the ſharpneſs and pricking of the Vinegar proceeds from theſe little Creatures, which is a vain thought that deſerves not a refutation; for they are only to be found in dead Vinegar; and I pray from whence have they their teeth ſufficient for the gnawing of Iron? But the whole corroſive force of Vinegar is more truly referred to the Salt having gotten a Flux: in the mean time thoſe little Creatures ſeem to be begotten by this means; it is ſufficiently known, that when very many Subjects are brought to putrefaction, the active Principles being thruſt out of doors, yet ſtill affecting their old dwelling, remain ſomewhere about the neighbourhood, and being joyned together, do often produce living Bodies; wherefore, when moiſt things putrifie, moſt often little Worms grow on their Superficies; but in Vinegar the buſineſs is a little different, to wit, becauſe the Elementary Particles are more fixed, therefore when the mixture of the Liquor is wholly diſſolved, the active Principles, although looſened, yet breaking very hardly and difficultly from the ſubſtance, meet together in the bowels of the Subject, and there mutually cheriſhing one another, cauſe thoſe little Creatures in the midſt of the waters.

Alſo the Bodies of living Creatures, being prepared for our Food, are diſpoſed towards putrefaction, if they are put up for ſome days, till the active Particles are looſened, and begin to be in motion, tending to exhalation; wherefore both the Fleſh becomes more flaccid, and in eating more tender and ſoft: and if they are kept longer, till the Saline and Sulphureous parts being carried forth into a Flux, do break out, preſently a ſtinking ſmell and putrefaction is induced.

There are many ways whereby fleſh is wont to be kept from putrefaction; the chief of which are, that it be pickled with Salt or Spices. Things are kept a long time incorrupt and very grateful to the taſt, with Salt: Dead Carkaſes are imbued with Spices, that they may remain a long while in their Sepulchers. As to the firſt, Brine or ſalt Pickle hinders the eruption of the Sulphur, and fixes it in the Subject by its embracement, and retains it. Spices, as they conſiſt of very active Principles, ſtir up a new Ferment in the Subject, the dead Carcaſe; and the implanted Elements of this, joyn into the ſociety of their motion, and retain many of their Particles flying away, yet longer in the Body: As Salt and Spices are made uſe of for the preſerving long fleſh, and Sulphureous things, (which alſo preſerve all other things from Putrefaction) ſo Vegetables, and their Flowers and Fruits are better conſerved with Sugar: for this by cheriſhing the active Particles of the Subject, reſtrains them within, and beſides, renders the Confections of a very grateful taſt.

Minerals,

Minerals, chiefly the ſolid and hard, becauſe they are indued with plenty of Salt and Earth, with little of Sulphur, and with a leſs quantity of Spirits, therefore they rarely, or not at all conceive Putrefaction: there is the ſame reaſon for reſinous things, which tho' they abound in Sulphur, with Salt and Earth, yet becauſe there is but a ſmall portion of Water and Spirits, therefore their frame is not eaſily looſened, neither are they obnoxious to Putrefaction. Among Minerals, common Water only, falls under this rank: for this, if it ſtand ſtill, or is kept long in a Veſſel, its Salt and Sulphur, though but in a little quantity, having gotten a Flux, begin to evaporate, and together to induce Putrefaction: but ſo long as water is in motion, theſe Particles are ſtill involved with others, and ſo by their mutual embrace, are detained from evaporation.

Artificial things and preparations, are no leſs ſubject to Putrefaction than Natural things; for Bread, and all manner of Eatable things or Food, Wine, Beer, and other Drinkable Liquors, alſo Medicinal Confections, being long kept, firſt loſe their ſtrength and vigor, and then afterwards are Corrupted: concerning which, we may obſerve theſe following things.

The more the things are Compounded, and have all the Principles conjoyned together, the ſooner, and the eaſier, do they enter into Putrefaction; wherefore Eatable things, prepared of Fleſh, Broths, Decoctions of Herbs, alſo many Medicines made after the Galenical way, are wont (unleſs preſerved with very much Salt or Sugar) to be Corrupted in a ſhort time: In the mean time, Diſtillations, and Chymical Preparations, which conſiſt of Homogeneous, or not much different Particles, are kept ſound a long while.

In Compounded things, if there be too great quantity of Water, things ſooner putrifie, for ſo the frame of the mixture is too looſe; ſo that the fixed Principles cannot take hold of the Volatile, or keep them back from flight: but thoſe in which Spirits abound with moderate Salt and Sulphur, if they are kept in a cloſe Veſſel, that they may evaporate but little, continue a long time, as may be perceived by ſtrong or generous Wine. The next to theſe, are thoſe things which are preſerved with Hony or Sugar, or in which the Saline Particles are in great plenty by nature.

Many of theſe, whilſt they are corrupted, are either made Mouldy or Rank, or they grow ſowr, or degenerate into a vapidneſs, or without taſte: things are made Mouldy, when the ſubtil Particles in the exhaling, are detained by the more thick, and cleaving together by their mutual embrace on the ſuperficies of the Body, grow into a ſoft Down or Hoarineſs, even as Moſs is brought forth by Stones, or Wood expoſed to moiſture.

Rankneſs or unſavory Taſte, happens chiefly in Sulphureous things, for Oily and Fat things, by Heat or Age, become Muſty or Unſavory, to wit, when the Spirit being very much exhaled, the Sulphureous Particles are too much exalted, and begin to evaporate.

Sharpneſs or Acidity is induced from the Salt, being too much carried forth and looſened; for when the Spirit is depreſſed, or exhaled, the Salt being fuſed, conceives a Flux, and ſo brings in a ſowrneſs: hence Wine, Beer, Cyder, alſo Milk, very many Eatable things, and the Juices of Herbs, when they are long kept, or if they are moved by too immoderate heat of the Air, or ſhaking, do eaſily grow ſowr.

Liquid things, degenerate into a vapidneſs or taſtleſneſs, when the active Principles, are for the moſt part gone forth, and nothing eminent beſides Water and Earth, or of the ſubtile parts, is left in the ſubject.

That I may contract what is aforeſaid; the corruption of every thing, is only the ſeparation and departure of themſelves from one another into parts of the Principles before combined, (the bond of the mixture being looſened) which motion, by reaſon of the diverſe diſpoſition of their breaking forth, (either with or without a ſtink) ends in Putrefaction or Rottenneſs.

Where Spirits abound, and that there is alſo plenty of Sulphur and Salt, and the Particles being looſened from their bonds, break forth in heaps; the mixture putrefies with a ſtink; alſo if it conſiſt of a thick ſubſtance, ſo that all the parts are not rightly ventilated, it conceives a heat from the Putrefaction: in ſuch a Corruption, the ſtink proceeds from the exhalation of the ſharp pointed Sulphur, or made pricking with the Salt: Putrefaction follows, for that the external humidity enters into the place of the Particles flying away: But the heat is produced by the Sulphureous Particles being moved together in heaps, and being ſhut up within the ſubject, that they gather together, and being united, act more ſtrongly. But if there be in the ſubject a leſſer proportion of Salt and Sulphur, ſo that when the mixture is looſened, the Particles are moved more ſlowly, and evaporate leiſurely, the Body grows dry, and is reduced to a waſting, without any ill ſmell, putrefaction or heat.

It will not be from the purpoſe to inquire in this place, from whence ſome empty Veſſels, and more moiſt bodies, by lying long, conceive a certain ſtink without Putrefaction; alſo other things being put into them, or lying near them, are wont to partake of their Evil; for which affection, a proper Latin word is not eaſily to be met with; in our Idiom it is called Muſtineſs, and in ſome ſort ſeems to be deſigned by the word *Mucor*, unleſs that *Δῆτος* or *Mucor*, points at

Bodies

Bodies infected with a certain Down or Hoarineſs, (which we call Mouldineſs) which here never happens. The conſideration of this matter is not improperly referred to the Doctrine of Fermentation, for this Tincture or Impreſſion of a ſtink, unfolds it ſelf far abroad, as if it were a certain Ferment, that the Veſſel but lightly imbued with it, infects whatever Liquors are put into it, and infuſions of them, even new and often iterated; we may obſervea twofold effect of this thing: For ſometimes the Veſſels being almoſt empty, at firſt vitiated, afterwards infect moſt Liquors, which they by chance receive, with a muſty odour: ſometimes more moiſt compacted, and ſolid things, being kept long, ſomewhat cloſe in a Cellar, contract this vice of their own accord; when in the mean time the contagion is not perceived to be in the place where they were kept; which things either may become muſty, not becauſe they are corrupted, for in moſt Spirit, Salt, and Sulphur, being yet contained, in the bond of mixture, the frame of the matter is kept whole, but the vice only conſiſts in this, that from the ſubjects after this manner diſpoſed, *effluvia's*, as it were, aculeated or ſharpned, fall off, and therefore become ungrateful to our ſmell and taſte.

Firſt, that any Veſſel may conceive a muſtineſs, there ſeems to be required in the firſt place, that its inward hollowneſs be large, and its mouth narrow; to wit, whereby a paſſage may lie open to the outward Air, and reſt may be granted to it, being entred in: for Juggs with broad mouths, alſo Bottles cloſe ſhut, do not eaſily get this fault. Secondly, that beſides the more ample inward hollowneſs, the ſides of the Veſſel be indued with pores, and very ſmall paſſages; for in theſe kind of little ſpaces beſmeared with humour, the Air being ſtrictly ſhut up, remains more quiet, and is apt to ſtagnate: Wherefore Glaſs Bottles are not ſo apt to ſuffer this evil, as Wooden, or Stone Bottles. Thirdly, that ſome moiſture, tho' very little, ſtick about the ſides of the Veſſel, or in its bottom, whereby the Air being entred may be intangled: for if the Bottles be hung up, with their mouth downwards, that all moiſture may drain out, they will never be muſty.

In the ſecond place: when Bodies, without any contagion of a Veſſel, contract a muſtineſs or mouldineſs of their own accord, we may obſerve, firſt, that they are of that kind, which conſiſt of Heterogeneous Particles, that is, a mixture of all the Elements together; becauſe the parts of Vegetables and Animals, and preparations of them, eaſily receive this evil; Minerals for the moſt part remain free from it: Secondly, that there be plenty of humidity in the concrete, for the more dry continue a long while without any hurt: Thirdly, that the Bodies be either kept in a heap unmoved for a long time, or elſe in ſome cloſe Cupbord, or Cellar, without Air; for ſo Wheat or Grain, in a heap, unleſs it be often moved, as alſo all Eatable things, being put up in a cloſe place, quickly grow muſty.

According to theſe poſitions we conjecture, that muſtineſs is made an affection to a moiſt inanimate Body, from the ambient Air, being admitted within its pores, and being got in, there ſtagnating, whereby the Elementary Particles of that mixture, being combined together with thoſe ſent in by the Air, are exalted into the Nature of a Ferment; that they diffuſe themſelves on every ſide with wonderful activity, and their *effluvia's*, as it were ſharpned, ungratefully ſtrike againſt the ſenſories of the taſte and ſmell. When therefore, ſome Subject becomes primarily muſty, a certain portion of the Air placed near, and hindred from ventilation, enters into its pores and paſſages, and there being intangled with a tenacious matter, is wholly ſhut up within the ſubſtance of that Concrete. From the mixture of the ſhut-up Air, the implanted little Bodies of the matter, eſpecially the ſulphureous and ſaline, acquire new heads; that afterwards, when they are exactly to be mixed with no other Body, yet very greatly Fermentative, tho' intermingled with any other thing, retain their own Nature, and being diffuſed through the large ſubſtance of the matter, infect the whole; to wit, they diſpoſe by that means, the Particles of that new matter, that they being armed with ſharp points, bring in like manner a trouble to our ſenſes: But in the mean time, from the muſtineſs, whether primarily ariſen, or received by contagion, the mixture of the thing is not diſſolved, nor the Principles diſſipated; yea, thoſe things which are wholly taſtleſs, do ſcarce at any time become muſty: the muſty ſmell depends chiefly on the active Principles, diſpoſed by a peculiar right, by the involved Air and their *effluvia's*; wherefore, if they almoſt wholly fly away from any ſubject, that is rendred almoſt incapable of this affection.

There may be obſerved a certain likeneſs between muſtineſs and an Empyreuma, or taſte of fire or burnt-too, for as in this, the Particles of the fire being intangled, and included by a tenacious matter, by their long ſtay there, pervert the implanted little Bodies of Salt and Sulphur, from whence their *effluvia's*, ſtrike our ſenſes with an ingrateful ſharpneſs; moreover, being mingled with other things, they affix to them, the diſpoſition of their pravity; ſo in muſtineſs, the Particles of the Air, being obvolved with a viſcous matter, and ſtagnating, they change by their preſence the ſaline and ſulphureous little Bodies, from their due temper, whereby they being as it were gifted with ſharp prickings, do ſtrike bitterly our ſenſories, and being exceeding fermentative, diffuſe their odour to others: the alteration being either way contracted, can ſcarce be blotted out, by any mixture with other things, or emendation by Art: The

chief means of helping of either, is by placing it in a reciprocal trajection, *viz.* Empyreumatical things, or tasting of the fire, are to be a long while exposed to a more moist Air, whereby the Particles of the fire may exhale: and musty things are to be held to the fire, or put to such things which may sweeten their Nature, to wit, quick Lime, Sulphur, or Stygian Waters, by which the parts of the included Air are driven away, and so the remaining little Bodies of the mixture are wont to recover their pristine state; wherefore, if musty Liquors are distilled, the Water falling into the Receiver, will be deprived of that stink: But the smatch of Fire, or Empyreuma, is not so easily mended by this Artifice.

So much for Fermentation, and the motion of the Principles, for as much as within the Confines of the same Subject, they dispose it, either to maturity and perfection, or towards dissolution and corruption. It now follows to treat of the motion of the same kind of Particles and Principles, for as much as some of one Body, do act on others of another Body, and by dissolving the mixture, do wholly draw them forth, and send them outward, or by precipitating it causeth them to go into parts.

CHAP. IX.

Of the Motion of Fermentation, as much as is to be observed in the Dissolution of Bodies.

FOR the Solution of Bodies, there are two great solvencies, or Menstrua, which exist from Nature; to wit, Water and Fire: Fire, if it be next and immediately applied, destroys most Bodies, drives away the Principles one from another, and as it were dissipates them into Air, Earth only, with a little Salt, being left behind; if it be mediately applied, it brings away some Particles, so that in the mean time others remain: After which manner it serves chiefly for Distillations, and Chymical Operations, and is also used in the Preparation of necessaries for our Food, both about the Boiling and Rosting of Meats. Water does not so readily destroy Bodies, but it draws forth some parts from the Subjects, and receives them into its own Bosom, and firmly retains them for various uses: But as it does not easily penetrate every Body, but leaves almost untouched those which are of a more fixed Nature, various ways are thought of, whereby the Menstruum of Water is made sharper, and is rendred fit for the dissolving of any Bodies whatsoever. For by means of the Bodies, which it ought to dissolve, and of the parts which it ought to receive in it self, it is armed as it were with some Weapons; with which it is able to unlock any Subject, and to possess now these, now those Particles. The Menstruum of Water is sharpned with Spirit, Salt, or Sulphur: to wit, either with each of these, or with more of them joyned together; we will first speak of the watery Menstruum, with the various sharpning of it, and afterwards of the fiery dissolvent.

Common Water most easily dissolves the more simple Bodies, except Sulphur; and hides their Particles, in its pores and passages; it readily receives Salts of every kind, and easily imbibes Spirits; it loosens the frame of Earth, and cherishes its more tender little bodies, in its embrace; but it is hardly mixed with Fat, and Oily things, and receives not their Particles, but by the coming between of others, but drives them forth to its superficies, as not miscible, or thrusts them down to the bottom.

Water in some measure enters the more compounded Bodies, whose frame is somewhat loose; and then receives into its bosom, some not simple Particles, but resembling the nature of the whole mixture: hence most Vegetables, also parts of living Creatures, and some Minerals, being put into common Water, do impregnate it with a certain vertue; and from most Metals, by a long maceration, it takes away some strength, though but small. Some Bodies are dissolved by Water, which yet a sulphureous or spirituous Menstrua leave almost untouch'd; as the Gums *Tragacanth*, *Arabic*, &c. also Salts and Sugar.

The first and most common way of sharpning, whereby simple Water may more easily enter the Bodies to be dissolved, is, that it be furnished with fiery Particles, or darts of adventitious heat; for so it is driven more deeply with a certain force, into Bodies, and destroys some thrids, as it were the smallest mites, in their most inward recesses. Wherefore we are wont to boil for a long while, the matter to be dissolved in water, or at least to infuse it in warm water, by which means, the more tenuious, and certain subtil Particles, which resemble the nature of the subject, are easily drawn forth, and impregnate the water, with the vertue of the whole mixture.

So much for the simple, or natural *Menstruum* of Water, to wit, for as much as its activity is wont sometimes to be promoted, by fire or ascititious heat. But this cannot be so simple, but

that

that it contains in it ſelf ſome Particles of another kind; as may be gathered from its eaſie Putrefaction; for oftentimes it is impregnated with ſpirituous, ſulphureous, or ſaline Breathings, contracted from the Air or Earth; that for the drawing forth the Tinctures of very many things, ſometimes it excels an Artificial *Menſtruum*; for that Acidulous or Spawiſh Waters, Mineral Waters, Rain Water, and *May* Dew, are of frequent uſe among Chymicks, for the remarkable faculty of diſſolving, with which they are ſtrong. Beſides, 'tis a vulgar obſervation, that ſome Waters moſt eaſily diſſolve Sope, and being throughly mixed with the ſame, cauſes in the liquor a great ſpume or froth; ſuch, if they be rubbed between the fingers, feel ſoft and gentle; but other Waters, which being handled with the hands, are more harſh, refuſe the mixture both of Sope and Oyl, and ſo are accounted unprofitable for the waſhing of Cloaths: theſe ſort of Waters, if they ſhould be evaporated in a Glaſs, oftentimes affix a Cruſt to its bottom and ſides; becauſe they are impregnated, more than they ought, with ſaline Particles, with which, when the ſaline parts reſiding in the Sope combine, the ſulphureous are carried away, and they being excluded, the pores are thruſt forth as not miſcible, to the top of the Liquor. When Fleſh is boiled in theſe Waters, it grows very red; which Tincture indeed being thence contracted, is a ſign, that thoſe Waters are ſomewhat imbued with Vitriol, or ſome other kind of Salt. But we will paſs to Artificial *Menſtrua's*, in which the watry Liquor is furniſhed with Spirit, Salt, or Sulphur, being gathered apart, or many of them together.

The ſpirituous *Menſtruum* of Water is made, when from a Body ſwelling with Spirits, a clear and limpid Water is diſtilled; as from Wine, or ſtrong Beer, or other Bodies truly fermented, and brought to exaltation: The kind of diſſolvent is hardly to be had ſo ſincere, but it is mixed with the Particles of more pure Sulphur, and ſometimes of a volatile Salt. The former kind of Liquor is called Spirit of Wine, which being ſubtil, and very penetrating, eaſily enters the Bodies, and parts of Vegetables, and alſo of living Creatures, but hardly Minerals, or not at all: it extracts from many things, not any Particles, or reſembling the Nature of the whole mixture, (as common Water) but chiefly Spirituous, and Sulphureous, the reſt being almoſt untouched; wherefore, it is wont to be uſed for the reſinous *magiſteria* of Vegetables, (which it draws forth almoſt ſincere or without mixture, under the form of Gum or Roſin) in the mean time, it is not ſo fit as common Water, for the extracts of Plants, which are not ſo indued with Sulphur: from ſulphureous things, as Benzoin, Sulphur, Olibanum, Styrax, Amber, and the like, it draws forth excellent Tinctures: It diſſolves the fixed Salts of Herbs, alſo of Pearls and Coral, before prepared with Vinegar, by a long digeſtion, and receives their Tinctures into it ſelf: it leaves Sugar, and Gums, being diſſolvable in Water, almoſt untouch'd. But there is another ſpirituous *Menſtruum*, that is ſharpned with a volatile Salt, ſuch is the Liquor which is diſtilled out of Blood, Harts-horn or Soot; it is far ſtronger than the former, and cuts moſt Bodies, except Metals, into parts, and oftimes deſtroys the forms of the whole mixture: yea, it moſt excellently diſſolves ſecondarily, the moſt fixed Metal, to wit, Gold, being firſt reduced into a Calx, by its proper *Menſtruum*, and reduces it into a Tincture, or potable Liquor.

They are accounted Sulphureous *Menſtrua*, which are brought forth of Sulphureous Bodies, under the form of an Oyl: theſe are prepared, either by diſtillation, ſuch as are chiefly the Oyl of Turpentine, Juniper, and the like; or by expreſſion, ſuch as are wrung forth of Olives, Almonds, and other Fruits, or Seeds of Vegetables. Things diſtilled are of more efficacy, than preparations by expreſſion; either of them draw forth ſome Particles, from Vegetables, or Animals; by the vertues of which, theſe Oyls being impregnated, they are made fit for Medicinal uſe. Yea they are conveniently enough made uſe of, for the extracting of the Sulphureous Particles of Minerals, which ſometimes they draw forth ſincere or unmixt: But if Oyl of Turpentine, or Lin-ſeed Oyl, draws forth by diſſolving, the combuſtible part of common Sulphur, in the mean time, the remaining ſaline parts, and untouched by the *Menſtruum*, grow into Cryſtals; as is obvious to every one, in the preparing the Balſam of Sulphur.

Mineral Bodies, in which the bond of Concretion chiefly depends upon Sulphur, as are the Fire-ſtone, Antimony, common Brimſtone, and the like, are in ſome ſort diſſolved by a ſulphureous *Menſtruum*, which draws forth of the Body, Particles of the ſame kind, the ſaline being being almoſt untouched: wherefore Oyl of Turpentine, Lin-ſeed, *&c.* draw forth a Tincture from theſe; in the mean time, ſaline *Menſtrua*, ſuch as are diſtilled Vinegar, or Stygian Waters, profit little for the diſſolving their Bodies: but that theſe, unleſs before Calcined, hardly are touched. But on the contrary, where the frame of the mixture conſiſts of a ſaline bond, ſuch as are Iron, Copper, and the like, ſaline *Menſtrua*, as *Aqua Fortis*, Spirit of Vitriol, Salt, *&c.* receive in the diſſolving, the Particles of the ſame Nature into themſelves, the ſulphureous being almoſt untouched. This plainly appears, in the ſolutions of Metals, but chiefly and remarkably in Camphire, which Stygian Waters reduce into a Liquor, in form of an Oyl, ſwimming on the *Menſtruum*; to wit, they diſſolve its frame, and receive ſome ſaline parts, on which the Concretion depends, into themſelves; in the mean time the ſulphureous being untouched, they are gathered together apart, on the ſuperficies of the Liquor. There is ſomething to be wondered

at concerning Antimony: to wit, that its Concretion being very irregular, that Mineral becomes exceeding unlike, not only to other mixtures, but alſo to it ſelf; for it is very lax, nevertheleſs much compacted; it lies open to the leaſt injuries, yet is almoſt impervious to the greateſt, ſo that it may equally number its loſſes, with its Victories: ſome of its Particles lie ſo looſe, that they are brought away by any Oily *Menſtruum*, or by a common *Lixivium*, or Lie: others in the mean while do ſo pertinaciouſly ſtick together, that *Aqua Fortis* cannot touch them, only *Aqua Regia* being poured upon it can know it; which ſo ſtrongly reſiſts it, that the fume raiſed up from thence, preſently obſcures the whole Room, wherefore there ſeem to be in this, parts wholly of a different Nature, ſome imperfectly mixt, *viz.* Earthy and Sulphureous, which are eaſily looſned by a fit ſolvent; in the mean time others wholly Metallic, perfectly mixt, coming near in ſome ſort to the Nature of Gold it ſelf; which therefore are only to be diſſolved, by a fit *Menſtruum* of Salt.

The ſaline *Menſtrua* are of divers kinds and natures, *viz.* of Vegetables, Animals, or Minerals. Among Vegetables are eminent, the ſowr Juices of Fruits and Herbs, Counterfeit Vinegars, acid Liquors diſtilled out of ponderous Woods, as Guaiacum, the Oak, and Box; in all which, the ſaline Particles having gotten a Flux, either by Art, or by Nature, give a notable ſowrneſs: or the Vegetable *Menſtruum* conſiſts of Salts of Tartar, or made by the cineration of Herbs, and diſſolved, which by the Fire are very much whetted, and acquire an acritude; in theſe the ſaline Particles are fixed, and in a condition oppoſite to a Flux. To the rank of Animals I refer the Spirit of Urine, Harts-Horn, *&c.* which although they are impregnated with Spirits, yet they take their chief forces from a Volatile Salt. But the ſtrongeſt ſaline *Menſtrua*, are drawn forth of Minerals, ſuch are acetous Liquors, which are moſt ſtrongly forced by fire, out of the Salts of Nitre, Sea Salt, Alumn, Chalcarth or Vitriol, and ſuch like.

Thoſe which are drawn out of Vegetables, as Vinegars, and acid Liquors, do beſt of all diſſolve Corals, Pearls, Shells, and Shelly ſubſtances: becauſe in theſe there is great plenty of Alcalizat Salt, with which the fluid Salt, which abounds in thoſe kind of acetous *Menſtrua's*, deſires to be moſt ſtrictly united; wherefore they being applied to the body to be diſſolved, enter its pores and paſſages, looſen the Complications of the Particles of the Alcalizat Salt, and ſnatch them into their own Embrace. Even after the ſame manner, the fluid Salt in a Vegetable *Menſtruum*, approaches the Volatile Salt in the Horns of Animals.

Theſe kind of *Menſtrua's* do corrode ſome Metals towards the ſuperficies; but do not ſo potently unlock their bodies by diſſolving, as Stygian Waters, ſome ſulphureous ſubjects, being before looſened by Calcination, do enter aptly enough, and from thence carry forth ſaline Particles. Wherefore, for the Salt of Tinn, Lead, Antimony, Soot, and others, being firſt reduced into a *Calx*, we uſe diſtilled Vinegar.

The Salts of Tartar, and the fixed Salts of Herbs, although they ſerve for præcipitation, rather than diſſolution, yet becauſe they conſiſt of ſharp, and very penetrating Particles, they are of egregious uſe: For watry *Menſtrua's* are chiefly ſharpned with theſe, for the extracting of the Tinctures of Vegetables. And altho' Bodies which abound with an alcalizat Salt, as Pearls, Corals, *&c.* are left wholly untouched by reaſon of the Homogeneity or agreeableneſs of the parts in either; and that alſo, they but little gnaw, only on the ſuperficies, being put upon Metals, and grow together with their Salt, and Sulphur, into ruſt; yet ſulphureous Bodies they readily enter, ſo they be looſened by the fire, and unlock and pull aſunder their joyntings or complexions; wherefore, for the making of the Milk, or *Magiſterium* of Sulphur, the Salt of Tartar moſt excellently conduces.

Saline *Menſtrua's* are moſt ſtrong, which are forced by diſtillation out of Minerals; to wit, out of Vitriol, Nitre, Sea Salt, Alumn, Arſenick; Acetous Liquors are diſtilled either from theſe ſingle, or from many of them mixed together; which as they are of the higheſt ſharpneſs, like to fire, readily enter moſt bodies, but chiefly Metalic bodies, and ſuch as conſiſt of a ſaline bond, and diſſolve them eaſily into moſt ſmall parts. Theſe Liquors are only ſaline Particles, which being driven by the force of heat, from the embrace of their Earth, having gotten by that means a Flux, are converted into water: as actual fire chiefly aſſaults ſulphureous bodies, and by deſtroying the body, draws to it ſelf the conſimilary parts; Stygian Waters (which are alſo called potential fire) eaſily pull aſunder bodies, which very much abound with Salt, as Metals; and break them, inviolable by fire, into moſt minute parts.

Concerning the Solutions of Minerals, we may obſerve, that their frame is not eaſily deſtroyed, or looſened into parts, as other Concretes of Nature; but for this, moſt ſtrong *Menſtrua's*, and thoſe chiefly Acetous, diſtilled from Salts, are required; the reaſon of which is, for that the Concretion of Minerals, depends moſtly upon great plenty of Salt, binding the reſt of the Particles, as with a bond; wherefore their ſubſtance is more ſolid, more hard, and compact, and only gives place to a ſaline *Menſtruum*. When any Mineral, or Metal is diſſolved, the fluid Particles of the Salt, in the *Menſtruum*, moſt eaſily enter the moſt ſtrict Complications of the fixed Salt in the mixture, and impervious to any other ſolvent, looſen them from their binding, and ſnatch them into their Embraces: after this manner, the Particles of the Salts being united,

and

and dilated by the Liquor, are hidden in the pores and paſſages of the *Menſtruum*; and together with theſe, ſtick, and are alſo ſupped up, by the *Menſtruum*, the more pure and minutely divided bodies of Earth or Sulphur, which were in the mixture; in the mean time, the more thick, and more ſtuffed with Earthineſs, are præcipitated to the bottom of the diſſolving Liquor: wherefore Gold and Silver are wholly devoured by the *Menſtruum*; but Iron, Lead, *&c.* and alſo Metallic Recrements, ſend forth from themſelves, in the diſſolving, Heterogeneous Particles, as ſo many off-ſcourings: when Minerals are broke into parts by this means, the divided Particles, and moſt minutely broken, (ſo long as they equally cohære with the Particles of the fluid Salt, which are in the *Menſtruum*) being diſperſed through the Liquor of the *Menſtruum*, and hidden in its pores and paſſages, are ſupped up, and rendred inviſible. Yea alſo, the humor of the *Menſtruum* being taken away, the remaining *Calx*, which conſiſts of the Particles of a mixt, and fluid Salt, combined together, is diſſolved in any other Liquor: but if after a Metallic ſolution, the fluid Salt be drawn off, from the Particles of the thing ſoluted, or by Calcination, it neither poyſes any Liquor it is put to, with a new adjection of fixed Salt, nor do the little bodies of the thing ſoluted fall through the pores of the *Menſtruum*, nor are they laſtly ſupped up, by any Liquor added to them.

But that among Metals, ſome are corroded by any acetous Liquor; in the mean time others, as Silver and Gold, require a peculiar ſolvent, as it were to be unlocked by an appropriat Key: and what is more wonderful, common *Aqua Fortis*, which eats Silver, leaves Gold altogether untouch'd: then the ſame Liquor by an addition of *Sal Armoniac*, is made a proper diſſolvent of Gold, and has no power upon Silver: The reaſon of thoſe may be thus underſtood: Gold and Silver are more compact Metals, very much cleanſed from earthy matter; wherefore they are not broken into parts by any ſolvent, but only by thoſe kind of *Menſtrua's*, which conſiſt of a Salt homogeneous or agreeable with them. But as the frame or ſubſtance of Silver depends upon a Vitriolic Salt, and that of Gold, on an Armoniac Salt (or of a more perfect kind; to wit, ſuch as is wont to be moſt ſtrictly complicated with Sulphur) hence *Aqua Fortis*, ſo long as it is ſtrong with a Vitriolic vertue, combines with the Salt of the Silver, and therefore unlocks its frame or ſubſtance, but doth not looſen the concretion of Gold, which depends upon an Heterogeneous bond: If that to this *Menſtruum*, *Sal Armoniac* be added, the power of the Vitriolic Salt is blotted forth, and the ſaline darts of the ſolvent are made fit only for the Gold, the Silver being untouched.

When Minerals are corroded by acetous *Menſtrua's*, we are not therefore to think, the ſame always to be reſolved into Elementary parts: that the Salt and Sulphur of them, may be had ſincere or unmixt, by this means (altho' ſome boaſt, that they are eaſily able to ſhew ſuch Analyſes of Metals) for that it appears to our obſervation, and frequent experience, that many of theſe are of ſo compact and ſolid a Concretion, that they cannot be broken, but into integral parts: as for example, Gold and Quickſilver, after what manner almoſt ſoever handled, when they are reduced into manifold Calxes, will at laſt by a ſtrong fire acquire their proper forms: *viz.* the ſaline Particles of the *Menſtruum*, looſen the bond of Concretion, whereby the moſt minute integral parts of the mixture ſtick one to another; but the ſame ſolvent, is not able in all things, to break aſunder the *Copula* of the firſt mixture, whereby the Elements are mutually bound together: ſo that for the moſt part Metallic Calxes, are only little bodies of the Concrete, broken into moſt ſmall little Globes, being involved by the ſaline Particles of the *Menſtruum*: Wherefore, fire being applied, thoſe corroſive Salts being pulled away from their Embrace, are wholly driven away; then the Metallic little bits, or duſt, as ſo many little particular Globes being fuſed, by the intenſe heat, coming together into one Maſs by melting, reſume the Species of the Metal: wherefore, they who commonly affirm, that the Salts of Minerals, for the moſt part, are only the ſaline Particles of the ſolvent, conjoyned with the Metal, reduced as it were into fine flower, without doubt ſpeak truth in the preparations of Sol and Mercury, or of Gold and Quickſilver; alſo the Salt or Sugar of Saturn or Lead, is nothing elſe: But that ſweetneſs comes only from the Vinegar; for if in the diſtillation of Vinegar, the joynings of the Veſſels are cloſed with Clay, and Salt, Chaulk, and Horſe-Dung, on the ſuperficies of this, grows together a moſt white Salt, wonderfully ſweet, in every thing like to that Sugar: but from ſome, *viz.* from Iron, Copper, and Silver, are prepared fictitious Vitriols, which are for the moſt part ſaline: For that the ſame, by diſtillation, may be forced into acetous Liquors, as the Metallic recrements.

Beſides the ſolvence hitherto recited (which, by means of the Particles, which are ſtrong in them, act upon a peculiar and determinate matter) I know that Chymiſts do boaſt wonderful things, of a certain univerſal *Menſtruum*, by whoſe inſpiration, every body whatever, may be eaſily reduced to its Principles, or firſt Elements: And tho' *Helmont* have bragged, that he had attained to this Secret by his own Labour, and now daily the Adepti of Chymiſtry, do aſpire to this end; yet the hopes and endeavours of moſt, have failed them in this work, even as in the Philoſophers Stone. There are alſo ſome other famous *Menſtrua's*, *viz.* The *Aqua Vitæ* Tartariſated of *Quercitan*, and his Philoſophic Vinegar, which are of noted uſe in the preparing of Medicines;

Medicines; but ſince I know nothing, or any ſtrange thing they have done, in the diſſolution of Bodies, we will paſs them over.

So much concerning ſolvent *Menſtrua*: about bodies to be diſſolved, a certain proviſion ſhould be inſtituted, whereby indeed their complections may more eaſily be unlocked, and cut into moſt minute parts: Wherefore the Concrete is now pounded into powder, now cut into little bits, that the way might lye open for the ſolvent, to its moſt inward receſſes. If that the frame of the ſubject be harder, and more ſtrict, that it will not give place, but of a long time, to the *Menſtruum*, before the diſſolution is begun, there ought to be adminiſtred ſome aperitives, or openers, whereby the Concretion may be firſt looſened, and ſomewhat opened: wherefore, the Tincture of Steel, is more eaſily extracted, if its filings be ſprinkled with the Juice of Limons, or the Spirit of Vitriol: in like manner Harts-Horn, or the ſhavings of Ivory, are handled when we would have the Decoctions of them quickly made: when formerly I have been very ſolicitous about this thing, *viz.* that I might render the more hard bodies eaſily ſoluble, in any *Menſtruum*, and that I had eſpecially tryed many things about Iron; after ſeveral experiments, at length, by a certain chance, and almoſt thinking of ſomething elſe, I found out a preparation, whereby without any Corroſive, or Acid Liquor, by the mediation only of a gentle heat, the body of Iron is opened, that being reduced into powder, gives immediately a tincture, to any Liquor, that neither Salts themſelves, are ſooner diſſolved in common water: By this means, I am wont to prepare ſuddenly, in great quantity, Mineral waters, which exactly reſemble our *Tunbridge* Spaws; and to render Wine, Beer, Milk, or Whey, with no trouble Chalibeated. By this means, Syrups, Tinctures, Extracts, or *Magiſteria* out of Steel, are moſt eaſily to be had. Moreover, plainly by the ſame Artifice, Corals, Pearls, Eyes, and Claws of Crabs, and all ſhelly things, are prepared, that their powders preſently impart to any *Menſtruum*, a tincture, or the vertues of the whole Concrete. And in this preparation, no ſtrange quality is introduced to the Subject, nor its own proper quality loſt.

When I had, by this means, learnt to unlock all Bodies whatſoever, conſiſting of a ſaline bond, preſently from the Analogy of this, was made known the means of unlocking Subjects, whoſe Concretion is wholly ſulphureous: for I am wont ſo to prepare common Sulphur, that its powder immediately impregnates any Liquor, with the tincture and vertue of Sulphur. The Spirit of Wine, ſuddenly contracts a deep colour, and very red, that being put into it. Common Water by the infuſion, or decoction of the ſame Powder, is rendered clearly ſulphureous, and gilds Silver, and by this means, from that Tincture, a præcipitation being made of White Wine, or Vinegar, the Milk of Sulphur is eaſily prepared, in great quantity. Out of ſulphurated Wine by this infuſion, I make a Syrup, than which there is ſcarce found a more excellent remedy, in the diſtempers of the Thorax. By this means, Tinctures, Extracts, Magiſtries, are prepared from Sulphur, with no labour, and without any ſmatch of the fire. By the ſame way Preparations from Amber, Benzoin, and other ſulphureous things, eaſily diſſolvable in any *Menſtruum*, are compoſed. But enough, and too much of this: we will now paſs to the other great diſſolvent of Nature.

CHAP. X.

Of the Nature of Fire: and by the way of Heat, and Light.

WE may almoſt pronounce the ſame thing of Fire, what the Philoſophers of old did of the firſt Matter, to wit, that it was potentially every where, and in all things; but in none, in act. For among theſe ſublunaries, Fire hath got no exiſtence of its own Nature, or certain means of duration: It is produced almoſt in every Subject, but is retained long in none, but it ſuddenly vaniſheth, and expires: yea, unleſs ſome external accidents, oftentimes ſhould concur for its production, I think it had not at all been in the World. Some have dreamed, that its Sphear is ſcituate under the Moon: but this was introduced only, for the making the Hypotheſis of the four Elements: for ſuch a thing ſeems conſonant neither to Senſe, nor Reaſon. That we may rightly ſearch out the Nature of Fire, we muſt ſeek in what Bodies it is chiefly to be found, and how they are diſpoſed; and then we may proceed to the unfolding its eſſence.

The Subjects moſt convenient both for the producing, and the maintaining of Fire, are of that kind, in which there are very many Particles of Sulphur, and but only a moderate portion of Water, Salt, and Earth: for theſe do hinder its inkindlings, and being plentifully poured on it, extinguiſh it being inkindled: Wherefore Bituminous, Fat, and Oily things, quickly take flame

flame: ſo alſo Chips, Straw, light and dry Wood: in the mean time, Metals, Minerals, the Glebe of the Earth, Dung, wet Straw, and green Wood, are hardly, or not at all, to be inkindled.

Secondly, We obſerve, that all the time the Fire continues in the ſubject, ſulphureous Particles fly away in heaps, and from the departure of theſe, the ſubſtance of the burning body is by degrees deſtroyed; in the mean time, very much of Salt and Earth, remains in the form of Aſhes, after the burning.

There is a third Obſervation, that when the ſulphureous Particles are wholly, or for the moſt part flown out of any ſubject, the burning wholly ceaſes, and the form of fire is quite deſtroyed; nor can it be renewed in the remaining matter, wanting of Sulphur.

Fourthly, We will note, that ſometimes ſome Bodies conceive a burning without the advention of another fire, only by their own effervency, and by the inteſtine motion of the implanted Particles, and of their own accord are reduced into Aſhes; as when wet Hay is laid up cloſe, it firſt grows hot, then afterwards breaks forth into ſmoke and flame; or the Wheels and Axel-trees of Carts or Wains, being heated by too great agitation, are inkindled.

According to theſe Poſitions, we may affirm, that the form of fire, wholly depends upon ſulphureous Particles, heaped up in any Subject, and breaking forth from it in heaps: and that fire is no other thing, than the motion and eruption, of theſe kind of Particles, impetuouſly ſtirred up. For Sulphur is of an exceeding fierce and untamed Nature, whoſe little bodies, when (the yoak of the mixture being ſhook off) they begin to be thickly heaped together, diffuſe themſelves on every ſide like a torrent, break whatſoever obſtacles are in the Subject, deſtroy whatever comes in oppoſition, or fling it down headlong. Nor do they only unlock their proper Subjects, but alſo lay open the gates and doors of any other Subject near, that they can reach to, and there incite to the like fury, all the conſimilary Particles of Sulphur, and provoke them to an eruption: wherefore fire every where inkindles fire.

The ſulphureous Particles, while they, heaped together within the confines of their ſubject, or on its ſuperficies, are agitated with a rapid motion, but are detained by the Embrace of other little Bodies, from a more free eruption, and more aggregated, conſtitute the form of fire; as is to be ſeen in burning Coals, or in glowing Iron; but when theſe ſort of Particles fly way by heaps, from the ſame ſubject, and bound together, they produce flame, which is only an heap, or rather a torrent, of the Particles of Sulphur flowing together, and conjunctly flying away: if Watery, Earthy, and ſaline Particles, are commixt with the ſulphureous breaking away, and are able to disjoyn and ſeparate them, only ſmoke is excited; which afterwards, the ſulphureous little Bodies more plentifully breathing forth themſelves, and getting together, breaks forth into flame.

The inkindling of Fire happens very many ways. The firſt and moſt ſimple is, when from hard Bodies ſtruck one againſt another, but oftneſt from a Flint ſtruck againſt Steel, ſparks of fire break forth; which being received in Tinder, made of a Linnen Cloth burnt to blackneſs, dilate themſelves, and then a Match, or ſulphurated thing, being applied, they cauſe the inkindling of a flame. Secondly, A Fire often happens in dry Wood, and dry things, when by the too great attrition of the parts, and agitation, being made hot, they conceive an inkindling of their own accord. And thirdly, when Bodies abounding with Sulphur, as Hay, or Flax laid up wet, (of which mention was before made) grow hot of their own accord, and afterwards are inkindled. The fourth way, is the moſt uſual, of introducing fire into any Subject, that it may be inkindled by another fire. We will a little more conſider the ſeveral proceſſes of theſe.

1. Hard Bodies ſtruck one againſt another, ſhake forth little ſparks of fire: as a Flint with Iron, or with a Flint; *Indian* Canes, the Fire Stone, and many other things. The reaſon of this is, becauſe the Particles of Sulphur, which reſide in the Superficies of a hard Body, if they are ſmitten by another hard Body, are not able to go back inward, (becauſe in hard things there is not afforded any ceſſion of the parts, from place to place) nor can the ſmitten Particles of Sulphur evaporate by degrees; but that by reaſon of the vehemency of the ſtroke, they are neceſſitated to break forth in heaps: Wherefore, when by this means, many of them are moved together, and are aggregated, they exhibit the apparition of fire. The ſparks being received into the half-burnt Linnen or Tinder, are dilated into a greater fire, for that the ſulphureous Particles, in ſuch a ſubject are eminent, and are brought, as it were, to the very top it ſelf of eruption or breaking forth, wherefore by the leaſt ſpark being moved or ſtirred up, a way being made they fly away.

The very ſame reaſon is for Wood, being made hot, and afterwards fired, by too great attrition; by which means, the Axel-trees and Wheels of Chariots, or of Mills, are frequently fired: for the Sulphureous Particles, being by this means very much moved, are more thickly heaped together; and when, having as it were made an Army, they are able to remove, or ſtrike away the reſt, they preſently break forth in Troops, and by their going away, cauſe a burning.

In

In Hay or Dung laid up wet, the Particles of Sulphur very much abound; which having gotten the watery Latex for a Vehicle, run themſelves into motion; but when for want of Ventilation, they cannot by little and little exhale, being ſtraitned within, and ſo brought into their exaltation, they are able to joyn more one to another, and mutally to incite themſelves: then afterwards, being very much heaped together, they unfold themſelves more largely, and begin to break the Dens of the Subject, and ſo produce a burning. For it is to be obſerv'd in any Subject, when the Particles of Sulphur, being more ſlowly moved, fly away by degrees, neither heat, nor fire, but only a drineſs, and leanneſs ſucceed. But if they are more rapidly moved, than that they may be able to exhale leiſurely, a heat is ſtirred up in the Subject: then if yet they are agitated more vehemently and impetuouſly, and being more thickly agglomerated, or heaped together, they break forth in heaps, a deflagration or flame follows the heat.

Fire being enkindled in any Subject, enters and enkindles whatever Sulphureous thing is next it. For as Saline *Menſtrua*, *viz.* Stygian waters, aſſault Metals, ſtuffed with Mineral Salt, and looſen their ſaline Particles, as being of kin, from the mixture; ſo alſo the ſulphureous Particles, being enkindled, break whatever ſulphureous particles are next them, and ſtir them up into the like motion of Burning, with themſelves.

Thus much concerning the Nature and Production of Fire: it remains that we next enquire into the Effects of Fire, and alſo concerning its Virtue and Efficacy; to wit, what kind of Bodies it diſſolves, and by what means; and alſo what uſes it ſerves for. The chief Effects of Fire are Heat and Might; either of them are excited by Emanations or *Effluvia*, ſent from an enkindled Body; but after a far different manner; for truly, Heat is moſt often produced at a diſtance, without Light; alſo Light, without any ſenſible Heat.

Heat, foraſmuch as it belongs to the Senſe of the Touch, is conceived, when a certain Paſſion is induced in the skin, or any other Organ of the Touch, whereby the little Fibres and nervous parts are drawn aſunder, moved into light ſpaſms or convulſions, and ſometimes (if the ſtroke be vehement) ſuffer a ſolution of the Union. This is wont to be done, either by the bringing near of Fire, or of another Body made hot by Fire, or by ſome other means: For from either, the ſulphureous or warming particles being excited, into a more rapid motion, and breaking forth by heaps, ſpread abroad, which, as ſo many little darts, being thruſt into our skin, or other Senſory of the Touch, either by tickling gently, they bring to it a pleaſing ſenſe of heat, or by ſtriking it more grievouſly, the troubleſom ſenſe of burning or ſcorching.

For the effect of Heat, Fire is applied to Bodies, either immediatly, and ſo either for the ſake of burning, roaſting, or boyling; or mediatly, *viz.* by the interjection of another Body. Bituminous things, Coals, and other things dug out of the Earth, alſo Vegetables, and chiefly their Leaves, and Woods, are burnt, for heat, neceſſary for human Uſes, and for the producing, and conſerving it. Stones are burnt for Lime; Vegetables for the preparing of Salts. The Fleſh of Animals is wont to be roaſted, and the Fruits of Vegetables; whereby they may become better food for men: For by roaſting, the ſuperfluous humidity is evaporated, and the ſulphureous parts being ſtirred by the neighbouring heat, are placed in their vigor and exaltation, by which means, they afford a more grateful food to the Palat, and of better digeſtion to the Stomack. By Fire Metals are fuſed or melted, and moſt Minerals, whereby they are either very much purified, or they are better formed into various figures by Smiths. Metals, and very many Minerals, alſo Salts, although they are not enflamed, and take a firing (becauſe they abound with leſs Sulphur, than Salt) yet by a violent fire, they glow, and ſuffer a fuſion; for that the ſulphureous particles of the Fire, enter the ſaline little Bodies, though moſt compact, and diſſociate them for the time; which however pulled one from another, preſently the Fire being exhaled, come again together, and are ſtrictly united.

Secondly, When Fire is mediatly adminiſtred, the particles of the ſoluted ſulphur, and heaped together into fire, are diſſociated, as when a Cloud is diſperſed into moſt little drops of Rain; wherefore they lay aſide the form of fire; but though diſperſed, they eaſily paſs through any impediment, and induce a ſufficient ſtrong heat to every Subject. By this means, Fire is accommodated to very many uſes, the chief of which, and the more accuſtomed, are, elixation or boyling, digeſtion, and diſtillation.

In Boyling, the Particles of heat do paſs into a watery *Menſtruum*, and being united with its particles, inſinuate themſelves deeply into the thing to be boyled: whoſe ſuperfluous humidities they carry away, digeſt the crudities, and carry them into a ſtate of maturity. Boyling is inſtituted, either that the Liquor might be impregnated with the ſtrength of the thing to be boyled, or that the thing to be boyled might be made tender, by the Liquor entring into it, and its Particles exalted: for Meats and all eatable things are rendred more grateful to the Palat by boyling, even as well as by roaſting.

Digeſtion is very much uſed in Medecines, that their more ſlow Particles may be carried to a greater activity; and ſometimes, that they being too fierce, might be fixed, and rendred more mild.

The moſt noble uſe of heat, or of mediat fire, is had in diſtillations; for the Particles of heat

heat, do pull away ſome Particles of the ſubject from others, (as it were by a Spagyric Anatomy) they reſolve all Bodies, into their parts and principles. But the conſideration of this thing, is too laborious and hard, to be inſerted into this Tract.

As heat reſpects the ſenſory of the touch, ſo light that of the ſight, and affects it ſo after a proper and peculiar manner, that nothing at all is diſcerned, beſides the rays of light, direct, or reflected: for the various appearances of Colours, and the divers proportions of Bodies, and whatſoever we ſee with our Eyes, is only light; to wit, either proceeding directly, or ſtrait from a lucid Body, or retorted from another Body, to the Eye, & ſo formed into various figures & colours. The conſideration of Light, contains in it ſelf, very many ſtupendious things, and is of deep ſpeculation; which are not however proper for this place: It will ſuffice to take notice here, of a few things, concerning its Original, Motion, and Perceptibility.

Light is wont to be diſtinguiſhed, either that it is Etherial, which flows from the Sun and Stars; or Elementary, which only proceeds from a fired Body, enkindled into a flame. It ſeems, that either is only flame enkindled in a greater dimenſion, and dilated into a moſt thin compoſition: for it appears to the ſenſe, that from ſulphureous things being inflamed; (as for example) from a burn-Candle, moſt thin *Effluvia's*, or moſt ſmall divided little Bodies perpetually do ſpring; which being diffuſed into an Orb, and ſtretched forth into right Lines, as it were from the centre to the circumference, are ſtill expanded on every ſide, in a great heap, and fill all the ſpace within the ſphear of its activity, with a luminous ray. The Particles of the flame, which firſt fall away or depart from a lucid Body, are ſtill driven forward by thoſe following behind; and ſo theſe alſo by others; and ſo by a continued ſeries of Particles of the flames ſtill ſucceeding, the beams of light are formed, and are thickly or cloſely directed into all parts.

The motion of theſe is exceeding ſwift; like ſtreams of water, breaking forth with a force, they paſs through the medium in the twinkling of an Eye, and, as thoſe waters, if the motion be cut off near the Spring, moſt ſwiftly vaniſh. When the Rays of light come directly from a Luminous Body, they conſtitute a medium, only clear or lucid, without the appearance of any colour or image: when the ſame Rays meet with a ſolid Body, they do not paſs rightly through it, but being either broken off, they are drowned or loſt, or elſe they are reflected and leap back or rebound, as when a Ball being caſt againſt a Wall, with a continued motion is ſtruck back, upon other parts, according to the Angles of what ſtopped it. The Rays of light, reflected from other Bodies, being fallen into the Eye, repreſent the Images of viſible things, and the varieties of colours. For as the ſuperficies of viſible Bodies are rough, and endued with little pores, and innumerable eminences, or riſings up, hence the Rays of light, being moſt thickly impacted in them, and reflected from every part, according to all the ways of inclinations, and directions, as far as they go, do meet together round about, into very many tops of Cones, in which the beams proceeding from the whole object, as from a baſe, repreſent the image or ſimilitude of the whole; and in theſe kind of images, the medium is every where planted, that wherever the Eye is placed, it beholds the image of the ſame thing, though not wholly after the ſame manner. But foraſmuch, as the beams of the ſame light, being impacted in every Body, and variouſly refracted and diſtorted, about its rough and unequal ſuperficies, from thence reflected as it were with turnings and windings into the Eye, they cauſe the diverſe Phænomena, or appearances of colours, to appear. For colours, and images of things, do not exiſt in their own nature, but as it were ſpectrums, only from another place, change their apparitions by the Rays of light. When dark night brings thick darkneſs to this inferior World, things are not perceived, but by the Touch, and loſe all their appearances: when the Sun reviſits the Hemiſphere, he brings forth a new Creation of things; and the whole Atmoſphere is filled at once, with a ſudden and manifold progeny; to wit, with infinite images of Bodies, and appearances of colours.

Therefore Light does not only illuſtrate the medium, that ſight may be made, as ſome would have it; but it alſo creates the very objects of ſight, and introduces them into the Penetralia or inward parts of the Eye, yea, to the moſt inward receſſes of the Brain. This doth the ſame Office for the Eye, as the Intellect doth for the Soul, to wit, it forms the *Idea's* or Images of Bodies, and renders them perceptible by the viſive faculty. Light only is able to penetrate the Coats and Humors of the Eye, to move the little Fibres of the Optic Nerve, and to ſtir them up into an act of ſenſation. Becauſe the Images of things, being forged by the Rays of light, variouſly reflected, and meeting together on the tops of the Cones, are ſtayed within the Pupil, or dark ſpot of the Eye; they ſeem as objects in a cloſe Chamber, admitted by a ſmall hole, to be repreſented to the life: and the Concave or Convex Glaſſes, whereby the parallel beams are broken, or the inverſe reduced or brought back, do egregiouſly ſupply the humors placed in the Eye, beyond the induſtry of human Art; by the help of which, the image of every object is painted, near the thin skin of the Eye, in its juſt figure and proportion: and then, from the motion, which this Image impreſſes on the little Fibres of the Optic Nerve, the act of ſight is performed in the Brain. Thus much for Heat and Light, the Speculation of which, tho' it may ſeem to be altogether beſides the Doctrine of Fermentation, yet foraſmuch as by the motion of

theſe kind of Sulphureous Particles, many other Phyſical Operations are alſo performed, a brief mention of them ought not to have been overpaſs'd in this place. But before we ſhall lay aſide quite the conſideration of Fire, it will be here worth our while to inquire concerning ſome Subjects, as it were irregular, to wit, in which fire ſhews admirable vertues, and beyond its common manner: of this ſort, are among Simples, common Sulphur, and *Sal Nitre*; among Compounds, Gun-Powder, and *Aurum Fulminans*.

Concerning common Sulphur we may obſerve, that it quickly catches fire, heat it immediately breaks forth into flame, ſuch (as nothing beſides) that by its deflagration it puts out the Kitchen-fire, that it ſends forth a bluiſh flame, and whitens all objects with its ſmoke or ſoot. If you behold the matter of this Subject, or the parts of which the mixture is compoſed, its Spagyrical Analyſis will exhibit great plenty of pure Sulphur, a moderate quantity of Vitriolic Salt, a little of Spirit, Water and Earth. For when common Sulphur is diſſolved, by the Spirit of Turpentine, the Sulphureous part impregnates the *Menſtruum*, with a very deep Tincture, and the Saline grows into Cryſtals: or when it is fired under a Bell, the Sulphur wholly burns, in the mean time the Salt being reſolved, and having taken a Flux, is fixed about the ſides of the Veſſel, and ſo exhibits a Liquor, moſt like the Spirit of Vitriol, or rather the very ſame. To which add, if you mingle the Oyl of Vitriol, and Antimony together, and diſtill it in a Retort, a Yellow Sulphur, juſt like the common, will be Sublimed in the neck of the Retort.

I ſay therefore, becauſe there are very many Particles of Sulphur in this Concrete, and that they lie looſe and unbound in the mixture, (to wit, neither divided and ſeparated by the coming between of Earth, or Water, nor much bound together by Salt) therefore they are of a moſt prompt motion: wherefore by the leaſt ſpark of fire, they break forth from the looſe frame; and becauſe very many run forth adoors together, therefore not a naked fire, as in every combuſtible thing beſides, but firſt of all and immediately a flame is inkindled. Its flame becomes bluiſh, becauſe 'tis almoſt pure Sulphur that burns, not mixed with the Particles of Water and Earth, as it is in Wood or Straw. The very ſame thing happens to Spirit of Wine being inflamed. It extinguiſhes the Kitchen fire, by reaſon of the little Bodies of Vitriolic Salt left behind; and the ſame being eventilated with the flame and fume of Sulphur, gives a white colour to things; the like to which, the *Effluvia's*, exhaled from the Spirit of Vitriol, or Stygian Waters, do effect.

Concerning *Sal Nitre*, we will take notice, that it is not to be inkindled at all by it ſelf; but to be melted by an intenſe fire: but being mixed with any Sulphureous things, it breaks forth into a flame, with a certain force and exploſion: For being added to common Sulphur, Antimony, or Tartar, it burns with a thundering noiſe; alſo if you put into melted Nitre, a burning Cole, or Wood, the flame is exploded round about, with a wind, ſo that the matter put in is flung up and down here and there, and often times flung clear out of the Veſſel: by this kind of deflagration, what is Nitrous is conſumed, the fixed Salt (which is Tartar) remains. When Nitre is diſtilled, Sand or Brick duſt, is mixt with it in a double quantity at leaſt; otherwiſe the Nitre melting is not at all looſened into a vapor. In the diſtilling the vapor ſent forth is very red; ſo that the Receptacle ſhines with a ſplendor, as if a flame were ſhut up within it: a ſharp corroſive Liquor is ſtilled forth, which diſſolves moſt Metals, alſo Gold.

Theſe things being truly weighed, it ſeems that this mixture conſiſts chiefly of abundance of Salt, and a little Sulphur, but theſe not fixed and idle, but either exalted, and ready for motion, and not without a certain reſiſtance bound together: to wit, the ſulphureous little Bodies, being rouled about by the ſaline, and as it were ſtrictly preſſed, ſtill endeavour to get forth; but being ſtrictly bound within, they are not able to riſe forth by their own ſtrength, or endeavour: but as ſoon as, by the mixture and inkindling of another ſulphureous Body, the Particles of the Salt are disjoyned, and their Priſons unlocked, preſently the included little Bodies of Sulphur, as it were breaking Priſon, fling themſelves forth with violence, remove every Obſtacle, and ſtrike the Air violently with a ſudden eruption.

The reaſon why fire doth not inkindle Nitre, being incloſed in a Veſſel, but only melts it, when in the mean time, any ſulphureous matter being fired, makes it to flame forth with a noiſe, is, becauſe the little Bodies, which fall away from the fire, enter the Nitre, make it a little looſe, and diſſociate the concretion of the Salt, but not ſo looſen it, that a way may be made for the included Sulphur: but by the addition of ſulphureous things, the ſaline compaction is more diſſolved, and is ſo far unlocked, that the Particles of the incloſed Sulphur fly away all together, and being freed from their ſtraightneſs, do hugely ſtretch themſelves abroad, and ſeek greedily an immenſe ſpace.

That there is plenty of Sulphur in Nitre, beſides its deflagration, the Geneſis of it ſufficiently teſtifies; for it is begot chiefly in places, where the ſulphureous Excrements of Animals abound. The uſe of it in agriculture argues the ſame thing, becauſe the fertility of the Earth depends very much upon it: And to this alſo, the flaming colour, ſhining in the diſtilling may perſuade.

From theſe premiſes, it will not be difficult, to unfold the nature of Gun-Powder, uſed in Warlike Inſtruments. For the ſudden firing, and vehement exploſion of it ariſe, for that thoſe very

very many, and almoſt infinite Particles of Sulphur, which conſtitute that fire-dilating Body, being fired, fly away together in a moment; all which breaking forth at once, a force being made, and deſiring a moſt free and ample ſpace, for their expanſion, violently move the Air, and all obſtacles, and ſo are exploded, or thruſt forth with a noiſe. There is in this mixture, common Sulphur put, becauſe its Particles are looſe, and ready for motion, and therefore apt to move a quick inkindling: there is added Charcoal duſt, becauſe in that alſo, the little ſulphureous Bodies (as is ſeen in Tinder, that is made of half-burnt Linnen) are brought to the very top of eruption; and therefore theſe preſently conceive an inkindling, and both theſe being fired, and oppoſed to the Nitre, they quickly looſen its frame, and ſend forth the ſulphureous Particles incloſed in it; which indeed break forth from their impediments with a force, and as the blaſt of a Bellows, encreaſe the ſtrength of the whole in firing. The Charcoal duſt is added in a moderate quantity; though it abounds with Terreſtrial matter, yet by reaſon of the Sulphur being carried forth in it, it accelerates the deflagration of this mixture: For the Coal and Nitre being beaten together, is ſooner fired, and with a greater exploſion, than Nitre and Sulphur: but if the Coals be added to this Compoſition, (as they are wont to make it for Cannon and great Guns) in a greater quantity than it ought, and improportionate to the Nitre, the immediate firing is ſomewhat retarded, by reaſon of the interjection of the Earthy matter; and it happens, that the ſulphureous little Bodies therein, apt to be too haſtily inkindled, are a little disjoyned, and ſo the ſubſtance of the infuſed powder, takes fire ſucceſſively, and by parts, and not all at once.

The reaſon of *Aurum Fulminans* does not ſo manifeſtly appear: but it ſeems wonderful, that the Calx of a Metal, otherways inviolable by fire, ſhould be brought into a powder, one grain of which, if it be but lightly heated by fire, is exploded with ſo great a force, and yields ſuch a noiſe, that is an hundred fold beyond Gun-powder. I know many deduce the cauſe of this, as in Gun-powder, from a Nitrous-Sulphureous mixture: For they ſuppoſe the Nitre drawn forth from the ſolvent *Menſtruum*, to joyn together with the Sulphur of the Metal, and ſo the powder from thence prepared, to get that fulminating force. But in truth, if this matter be better thought on, it will appear far otherways; becauſe this golden thundring powder, is not at all inkindled, as preparations of Nitre with Sulphur: for if fire be put to it, it goes off only ſucceſſively, by grains, nor as in Gun-powder, doth the whole fulminate at once; but being put into an Iron, Silver, or other convenient Veſſel, and for ſome time heated, by a ſudden fire, at length all the Particles being ſtirred together into motion, it is exploded with a mighty noiſe; but yet being exploded, it yields neither flame nor ſparks, neither is the Gold loſt. For if this powder fulminates in an open Veſſel; whatſoever is of Gold, remains after the thundring, in the form of a purple powder; and may be gathered up. That the genuine cauſe of this may be extricated, there are ſome things to be obſerved, concerning its preparations, which will give no ſmall light.

For the making of this powder, it is altogether requiſite, that a ſolution of Gold be made with a *Menſtruum*, impregnated with Sal Armoniack, or at leaſt Analogical to it: for I have tryed it in vain with the Spirit of Nitre, Salt, with the Bezoartic Spirit, and ſome others. Then next it is requiſite, that the Calx be precipitated with Oyl of Tartar; for if the ſame be brought into a powder, with Silver or Mercury being caſt in, it loſes its thundring force. Alſo, if the Liquor of the Tartar, be too precipitately poured in, that with the great heat, a repercuſſion of the thing ſoluted be made, it often loſes its fulminating vertue: but a precipitation being leiſurely made, the powder ſetling in the bottom is waſhed away, by the often pouring on of warm water, which, though it be moſt often waſhed and dryed, far exceeds the weight of the diſſolved Gold.

According to theſe poſitions, it ſeems moſt likely, that whilſt the Gold is diſſolved by an appropriate *Menſtruum* for this buſineſs, ſome little Bodies of *Sal Armoniack*, (or ſome other reſembling it) being greatly akin to the Gold, do moſt ſtrictly cohere with its Particles; which then by the Salt of Tartar leiſurely in the precipitating infuſed, are more fixed, and more ſtrictly tyed faſt together: and then the exploſion of this powder, or ſolary Calx, is nothing elſe than a violent eruption of thoſe kind of Salts, from the Coheſion or Embrace of the Gold. For when the powder prepared after this manner, is brought to the fire, or is otherways made hot, the heat cauſes the *Sal Armoniack* Particles, or others of the ſame nature affixed to the ſolar, to diſſociate; which notwithſtanding, (when they hardly depart one from another) are not pulled aſunder, but by a ſtrong and continued heat: yet afterwards being pulled aſunder with a certain force, by reaſon of the ſudden and violent breaking off, they ſtrike the Air impetuouſly, and ſo cauſe a moſt ſtrong noiſe, for their bulk. But in the mean time, if the exploſion be made under a Silver Spoon, you will ſee a ſeparation made of either Particles, here the ſolar of a Purple colour, there the ſaline of an Aſh colour. But that this powder doth not make a noiſe, unleſs it be leiſurely precipitated with the Oyl of Tartar, it is becauſe ſome Particles of the Salt of Tartar, being before bound together with the *Sal-Armoniack* Particles, do couple together, by which means all are more ſtrongly combined: For the Salt of Tartar being pounded with the mixture of Nitre and Sulphur, fixes their Particles for a time; that this Compoſition is not pre-

ſently inkindled by heat; but afterwards is exploded with a ſtrong noiſe. And powder prepared after this manner ſeems to imitate the nature of *Aurum Fulminans:* and it is probable that from other Minerals diſſolved and precipitated by reaſon of the ſtrict Coheſions of the Salt with the Metallick matter, and their violent abruptions, thundering Calxes may be prepared. That truly the preparation of this chiefly depends on the Combination of the Salts, it appears, becauſe, if in the precipitating (as I have known it ſometimes to have hapned) the Oyl of Tartar, being too haſtily infuſed, the Complexion of the Salts is diſſolved with the Metallic matter, the powder falls in ſmall quantity to the bottom, and of a very Purple colour, whoſe grains are fragments of almoſt moſt pure Gold, and therefore they do not fulminate at all: afterwards in that precipitated Liquor, very many ſlender Cryſtals grow together, which are indeed the Salts, having ſuffered a Divorce from the Metal. Beſides, that the Salt of Tartar, brings ſomething to the preparation of this powder, it is a ſign, becauſe thoſe things which take away the fulminating force from this, are of the ſame Nature, which chiefly work upon the Salt of Tartar; as a beating it together with common Sulphur, Spirit of Salt, Oyl of Vitriol, or of Sulphur: for theſe grow hot, and greedily deſire to be joyned with the Salt of Tartar, and ſo they call it away from the Embraces of the Gold; by which means the Combination of the Salts, with the Particles of the Gold, is looſned, and therefore loſes its Gun-like force. What is commonly ſaid, that this powder will be preſently inkindled, or exploded, by a moſt light heat, or by ſhaking it in an Iron Ladle is nothing true, as appears to me, for I have often tryed it. Nor is it more worthy of belief, what is ſaid, that this only forces downwards, and breaks the thickeſt hollow Pipes with its force; in the mean time, that it doth not move or ſhake any thing laid over it, becauſe long ſince I made tryal after this manner; Two grains of this being laid in a Silver Spoon, I covered with a Doller, then a Candle being held under the Spoon, upon the exploſion of the powder, there followed a great noiſe, and there was a little hollow made in the bottom of the Spoon, almoſt through, and the piece of mony was carried up with a force to the Cieling, wherefore, when this *Aurum Fulminans* is exploſed, its force is diffuſed round.

Altho' vehement heat, and incited, and alſo the emiſſion of Smoke and Soot, depends for the moſt part upon fire; yet ſometimes we perceive it to be produced in ſome ſubjects, and that in a very high degree, without its being actually inkindled. A moſt known inſtance of which thing is, quick Lime ſprinkled with water: which alſo Stygean waters ſhew, being mingled with Iron, the Butter of Antimony, and with the Salts of the ſtagma of Vegetables. The learned men, *Gunter*, *Conringius*, *Hogelandus*, and almoſt all that have touched on the Doctrine of Fermentation, have delivered the effects of this Nature, as eſpecial examples of Fermentations, wherefore it will be worth our labour, to inquire ſomething concerning each of them: but on this condition (which I alſo have obſerved in other diſquiſitions) that I willingly let alone the opinion of others; for a Traveller had rather drink at the Fountains themſelves: I will then as briefly and ſuccinctly as I can diſpatch the buſineſs.

Quick Lime is made of the Lime Stone, alſo of many others (excepting only ſuch which conſiſt of a reddiſh, and as it were ſandy grain) being Calcined in a cloſe Furnace for many days, with a reverberating fire: by this means, the frame of the mixture is looſned, that it goes into a friable matter, or that may be crumbled, which by reaſon of the high aſtriction or binding nature, in which it excels, ſerves moſt excellently for the making of Cements for Walls: This Calx or Lime being taken from the Furnace, retains ſtill the form of ſtone, and ſeems cold to the touch, but water being poured thereon, it ſwells up, and grows wonderfully hot, ſending forth ſmoak, that it burns all Bodies that are put into it, beſides it falls of it ſelf into a white duſt: To which Particles this motion and heat ought to be aſcribed, *viz.* whether to thoſe implanted in the Lime-ſtone, or to the others acquired by the fire, doth not eaſily appear: but that we may looſe this knot, if we can, I have inſtituted this Analyſis of quick Lime. I put about half a pound of it into a large Cucurbit, then water being poured thereon, I fitted the little Head with a capacious Receiver; by and by, within five minutes of an hour, the matter began to ſwell, and to grow very hot; then a ſmoak, and a breath being raiſed, all the Veſſels became ſo hot, that I could ſcarce touch them with my hands. A clear water diſtilled forth into the Receiver, about ſix Ounces, which was not ſharp, but of a Stypticor Aſtringent ſweetiſh taſte; the remaining powder in the Cucurbit, I boiled with common water, and the Lye thereof made, I endeavoured to boil away with a gentle fire; while it did evaporate, there gathered together on the ſuperficies of the Liquor, a white and crufty little skin, alſo of a ſweetiſh taſte, and the ſame being taken away, preſently a new one ſucceeded; the humor being at laſt wholly exhaled, there remained in the bottom nothing that was ſharp or ſalt.

We may collect from this, that this heat doth not proceed from the implanted Principles of the Lime-ſtone, *viz.* either ſaline or ſulphureous however moved within themſelves: for only a ſweetiſh Salt was to be found in it, which was alſo Volatile; and it is a ſign that there is not much Sulphur in the Lime-ſtone, becauſe by a long Calcination, the form of the mixture is not quite deſtroyed, nor its ſubſtance wholly broken: wherefore, it is very likely, that whilſt theſe ſtones are burnt in the Furnace, ſome Particles of fire do ſtrictly cleave to the ſaline, and ſo reſide

in

in that mixture, as it were ſtrangers; which whilſt they lie aſleep, and continue idle, and being ſeparated one from another, by the coming between of Earth, although they are very many, do not raiſe up heat; For all heat depends upon motion: but when water is poured to it, thoſe fiery Particles, being thruſt out of their Cells, flow together, and fly away by heaps from that Inn; ſo breaking forth by Troops, they cauſe a very intenſe heat, and becauſe diluted with water, only a ſmoak, and not an actual fire.

It is a ſign that little Bodies of fire, or fiery Particles, do ſtick a long while in matters Calcined, becauſe Iron Inſtruments, according as thoſe Particles are driven forth of their pores, more or leſs, leiſurely or by heaps, become ſoft or hard; tough or brittle: moreover, it is obſerved, that Bricks, or freſh Earthen Veſſels, being dipped in water, cauſe a certain hiſſing; alſo Tobacco Pipes, if one end be put into water, and the other brought near to the Ear, yield a certain ſharp noiſe and rumbling: add to theſe, that fixed Salts being calcined, or having ſuffered a flux by the fire, become far ſharper; alſo Stygian waters, by reaſon of thoſe kind of little Bodies involved therein, which afterwards leiſurely evaporate, perpetually ſend forth ſharp fumes: and when theſe are poured upon ſaline Calxes, not only an Ebullition is raiſed, by reaſon of the diſagreeing Particles of the Salts, which ſtrike one another mutually, whereby they might be more ſtrictly combined; but beſides, heat and ſmoak ſucceed, which for the moſt part ariſe from the fiery Particles being ſhuck out of their Dens. But it is not eaſie to give a reaſon why quick Lime, and no other Concretes, retain ſo copiouſly thoſe kind of fiery Particles, and yield a ſtrong heat, water being poured on them.

'Tis plain enough, that when the ſulphureous Effluviums of fire, (foraſmuch as they are moſt penetrating) enter all Bodies whatſoever, brought near, affect them after divers manners: thoſe which are more lax, and ſtuffed with active Principles, are deſtroyed wholly by burning, and becauſe their ſubſtance decays, the fiery Particles, as Soldiers in a City ſpoiled by themſelves, do not continue long in the ruined place, but go farther, and move their Tents: but where the Concretion of the Subject is very compact, and that its Elements cannot be ſo pulled in pieces by the fire, that they rather grow ſtiff, as is ſeen in Metals, Glaſs, Bricks, and other things made hard, either by boiling, or fuſion; the fiery Particles entred in, being received in an incommodious Inn, preſently go forth again; and therefore few are wont to ſtay in mixt things of this kind, or in things fuſed, or calcined: but if fire be ſo applied to the more hard Concretes, of which ſort are moſt ſtones, and ſhelly Concretes, that the bond of the mixture be unlocked, ſome parts, *viz.* the watery and ſulphureous are driven away, and ſo ſome ſpaces are made hollow, very fit for the receiving any ſtranger; in the mean time, that the frame of the matter be not wholly deſtroyed, but that it may continue its compacted and ſtony form, which flows not away together with its Particles, and ever threatens its ruin; in ſuch a Subject, chiefly the Particles of fire, poſſeſſing the ſpaces of the parts flown away, copiouſly remain; and there cleaving cloſe to the ſaline little Bodies, being detained one from another, by the coming between of the earthy, lie quiet; which notwithſtanding afterwards, being violently driven from thoſe Inns, are able to produce by their eruption, an intenſe, and almoſt fiery heat: in the mean time thoſe ſaline little Bodies, are ſo looſned, by the long familiarity of the fiery, and by the embrace of one another, and of the ſtrangers, that they become Volatile, and being diluted with Water, for the greateſt part evaporate with it; and the remaining Salt, becauſe alſo Volatile, and having ſuffered almoſt a divorce from all the reſt of the Principles, is both ſweetiſh, and becomes deſirous of conjunction, and aſtringent; and therefore alſo is of excellent uſe for plaſtring of Walls.

But that Stygian Waters, being poured upon the Stagma's of fixed Salts, produce heat, and the ſame mixed with Iron, or the Butter of Antimony, ſtir up a mighty ardour, with a blackning ſmoak, the reaſon ſeems plain. As to the Stygian Waters, and fixed Salts, it may be ſaid that both theſe Concretes are only Salts, having got divers ſtates by the fire, and ſo either being very much ſtuffed with fiery Particles (which are the moſt minute atoms of Sulphur:) But they being confuſed together, do forthwith ruſh into mutual embraces, and becauſe the Particles of either, are made unlike, therefore, whereby they may be more ſtrictly united, there is made a great attrition of parts, and together an excuſſion of the fiery Particles, from whence the great ebullition, with a heat is excited: when the ſame *Menſtrua*, are poured on Iron, or the Ice of Antimo, the Salts of either come together, and ſhake forth the fiery Particles, and alſo the ſulphureous Particles, before implanted in either Subject; which flying away in heaps, cauſe a ſmoak with a heat, but not a flame.

CHAP.

CHAP. XI.

Of the Motion of Fermentation, as it is to be obſerved, in the Precipitation of Bodies.

WE have hitherto treated of the Solutions of Bodies; it remains now, that we ſpeak of Precipitation: This is performed only in Liquids, which, when as they are ſtuffed with Heterogeneous Particles, are compelled by a matter Precipitating thoſe Particles, to ſeparate one from another, and to obtain for their ſubſtance, divers places and conditions: wherefore, ſince in this operation, there is an agitation and motion of parts, its conſideration ought to be referred to the Doctrine of Fermentation.

Precipitation is performed, either in Natural things, as chiefly in Milk, Blood, Urin, and perhaps in ſome others; or in Artificial things, which are of a divers kind and nature: but they may be deſcribed and ranked in a certain order, according as the Liquor to be Precipitated, or Precipitating, is either Spirituous, Sulphureous, Watery, or Saline: beſides, according as the Particles ſeparated from the reſt, are either Elementary, (*viz.* either Sulphureous, Earthy, or Saline) or Integral, which participate of the nature of the whole mixture, and are only very ſmall portions of it very much broken.

There are two common and known ways of Precipitation, whereby is made from Milk, both Cheeſe, and Butter: As to the firſt, if any ſharp thing be poured into warm Milk, the thicker and Cheeſie parts, preſently ſeparate from the ſerous and thinner, and are gathered together into a thick ſubſtance. The reaſon of which conſiſts in this: Milk has a ſomewhat thick conſiſtence, and its pores and paſſages are very much beſet, with the thicker (to wit, the Cheeſie) contents; wherefore when ſomething more ſubtil and penetrating, (as is Rennet) paſſes through the Liquor, it eaſily thruſts forth the more thick Particles, with which the pores were poſſeſſed; which then mutually Embrace one another, and are ſeparated apart from the thin, and Wheyie Liquor. When Milk is kept long to a ſourneſs, it is Precipitated after the ſame manner, without Rennet, by warming it over the fire. For in ſtale Milk its Saline parts get a Flux, then being ſtirred up by the fire, ſupply by their own ſourneſs the turn of Rennet; yea, it is not improbable, that the fluid Salt in the Rennet provokes the Saline Particles of the Milk, into a Flux, and that for this reaſon chiefly its Coagulation ſucceeds: for that the Saline parts having gotten of their own accord a Flux, ſo bind the pores of the Liquor, that the more thick Contents are willingly exterminated from them: wherefore we do ſay, for that reaſon, the ſame thing happens, when a Flux of the ſame Salt is cauſed by ſome thing elſe put into it. But that the Coagulation of Milk happens, not only by reaſon of the paſſages and pores being poſſeſſed by a ſtrange Body, the ſign is; becauſe the Salt of Tartar, tho' exceeding Precipitatory, effects nothing of this, and this effect is excited almoſt only by four things. Sugar hinders the Precipitation of Milk, and many other Liquors, becauſe it reſtrains the Flux of the Acetous Salt, and as it is eaſily ſoluble, and its Particles are ſoft and blunt, they extrude not the former Contents implanted in the Liquor, but fill all vacuities, that afterwards there is no ſpace whereby another Precipitating Liquor may unfold it ſelf, and break into anothers quarters.

But Country People are wont to make Butter of the Flowers or Cream of Milk, kept for the moſt part to a ſourneſs, only by ſhaking or Churning it. The reaſon of which (as it ſeems to me) is this: In Cream there is great plenty of Sulphur, with which alſo a mean portion of Salt and Earth is mixed, as may be conjectured, both by the ſourneſs of the Liquor remaining of the Butter, or the Butter-Milk, and by its thicker conſiſtency. In this mixture, the parts both Saline and Sulphureous are in motion, and a flux: but as the Liquor is thicker they cannot preſently fly away: wherefore it remains, that if the bond of the mixture be further looſned, they will ſeparate into parts, and that firſt the ſulphureous Particles, which exceed the others in power, are congregated together with a mutual embrace; wherefore theſe two things, the Churning of the Cream performs, *viz.* it brings the ſulphureous parts by their often obvolution together, whereby they do the better intangle themſelves, and mutually enſnare one another; beſides, it breaks their mixture with the reſt. For this reaſon, in the Winter time, (when Cream is thinner, and abounds leſs with Sulphur) Butter is hardly made. Beſides, the admixtion of Salt or Sugar wholly hinders its making; becauſe by the coming between of thoſe little Bodies, the Sulphureous parts are hindred, from a mutual adheſion.

The

The chief Precipitation of the Blood, which is performed within a living Body, is made in the Reins; where, not without the ſtrength of a certain Coagulum, or Rennet, the ſerous matter is ſeparated from the reſt of the Blood; juſt as Whey from Milk: For which reaſon Diuretical things are of the ſame nature, as thoſe which bring a Coagulation to Milk; and therefore, becauſe they more Precipitate the Blood by fuſing it, they cauſe a large profuſion of Urin. The Blood being ſent forth of the Veſſels, ſeparates into various ſubſtances, by its own diſpoſition: whilſt it is warm, it is variouſly Precipitated, by ſome Liquors poured to it, (in like manner Urin) not without a pleaſant ſpectacle. If you pour upon warm Blood the Spirit of Wine, Harts Horn, Soot, Vitriol, or other Liquors, chiefly Spirituous or Saline, a wonderful Ebullition, and heat is ſtirred up; whence we may conjecture, after what manner is grows turgid, in Feavers. But before the reſt, the Salt of Tartar, and a Solution of Alum, procure both in Blood and in Urin, a great perturbation of the Liquor, and falling down of the parts: for theſe diſturb all the Contents in the pores and paſſages of the Liquor, and by their aſtriction, very much lock them up for a long time.

Precipitation in Artificial things is of greater note and uſe: for this for the moſt part follows Diſſolutions, and ſucceeds them as it were by a certain right of Order; becauſe this takes out of their Jaws, and, as it were, lays by the prey, which all *Menſtrua* take by diſſolving. According to the diverſity of the *Menſtruum*, and of the Body diſſolved, Precipitation alſo variouſly happens: but in ſome Subjects there are two chief remarkable things, concerning the manner of Precipitation; to wit, the ſoluted Particles, immerſed in the pores and paſſages of the *Menſtruum*, are wont to fall out of them; either by reaſon of the narrowneſs of the containing ſpace, or elſe by reaſon of the Contents being increaſed in weight and bigneſs: for in ſome the pores of the Solvent, being either leiſurely bound up, or beſet with a ſtrange Body, ſhut forth from their Cells, the little Bodies of the thing ſoluted, and ſend them to the bottom; as may be obſerved in Sulphureous Solutions, or ſuch as are made of the whole mixture of integral parts, in a thin Liquor; which are diſturbed, and lay away their Contents by external cold, ſimple water, or at leaſt by any Acid infuſion. After this manner, reſinous Tinctures, alſo of Sulphur, Olibanum, Benzoin, and the Infuſions and Decoctions of Vegetables, alſo Urin, Milk, and Blood, are wont to be Precipitated: but in ſeveral others, beſides that the pores, and paſſages of the *Menſtruum*, are either leiſurely drawn together, or poſſeſſed by a new gueſt, alſo ſomething new grows to the Particles of the thing ſoluted from the Precipitating matter, whereby being increaſed in weight and bulk, they can be no longer ſuſtained; but that they are neceſſitated to ſink to the bottom. This is chiefly ſeen in the Saline Solutions of Minerals, which are only Precipitated by the Salts; whoſe Particles preſently cleave to the little Bodies of the thing ſoluted, and increaſe their ſubſtance, that preſently they deſcend to the bottom by their own weight: For in Saline Solutions, the little Bodies of the thing ſoluted, are ſtrictly bound together by the fluid *Menſtruum*, with the Saline Particles; and the Particles run haſtily and are heaped together into the Embraces of the ſame fluid Salt, from the Precipitating infuſion of the fixed Salt: wherefore, when theſe three, (to wit, the little Bodies of either Salt, and of the ſoluted matter) do cohere together, they conſtitute greater grains than can be contained in the narrow ſpaces of the *Menſtruum*, and therefore being thruſt out, they fall down towards the bottom: That this does truly happen after this manner, the great affinity, both of the fluid and fixed Salt, is a ſign; that the Particles of both being placed near, or mixed together, are preſently combined in one: alſo, becauſe many Solutions of Minerals, are preſently Precipitated by a fixed Salt, but not by Vitriol or Alum being put in, which do much more bind, and ſtop up the pores of the Liquor. Thirdly, It appears clearly even to ſenſe, becauſe that the matter put for a Precipitate, far exceeds the thing ſoluted in bulk and weight, and is impregnated by the fixed Salt adhering to it. But theſe being thus diſpoſed, we will deſcend to the particular caſes of Percipitations, foraſmuch as Precipitation is made manifold; to wit, according to the diverſity of the *Menſtruum*, of the ſoluted matter, and the Precipitating infuſion.

Simple Water, though it do not well ſuſtain the Particles of the mixture which it receives into it ſelf by Infuſion, or Coheſion, yet hardly ſends them away by Precipitation. For the pores of this *Menſtruum* are too open and looſe, wherefore the Precipitating matter, doth not eaſily ſtrike the little Bodies of the thing ſoluted: in the mean time, by reaſon of the more looſe frame of the *Menſtruum*, ſome parts of the ſoluted Body ſink down; others of their own accord evaporate, from whence that Liquor doth not long keep the Vertues or Tincture, with which they are impregnated by another. As ſome more thick parts and Terreſtrial may be thruſt down to the bottom, or otherways ſeparated, we put in the Juice of Limons, or ſome acid thing, or boil in it the whites of Eggs, to wit, that whatſoever is thick might cleave to their viſcous ſubſtance.

Spirituous and Sulphureous *Menſtrua*, being impregnated with the Sulphureous Particles of the thing ſoluted, eaſily lay by their burden; for they are Precipitated by common, or any

diſtilled

diſtilled Water; as is ſeen in Sulphureous and Reſinous Tinctures of Sulphur, Scammony, Benzoin, Frankincenſe, and others of that kind, prepared by the Spirit of Wine, or Oyl of Turpentine, which preſently grow Milky, by Water or Phlegm being infuſed. For in theſe ſort of Solutions, the pores are wholly poſſeſſed, that they admit nothing beſides the thing ſoluted; and beſides, both the Liquor, and ſoluted Matter are ſo thin, that they eaſily give place to any thing elſe being infuſed.

When *Menſtrua's* of this kind are filled with Saline Particles, as we may obſerve in the Tinctures of the Salt of Corals, of Tartar, and ſuch, Precipitation does not preſently ſucceed from Common Water, but from an Acid Liquor, as the Spirit of Vitriol, Salt, *&c.*

Saline *Menſtrua's* impregnated by the Solutions of Stones or Metals, are moſt eaſily Precipitated by Saline Particles, and ſcarce by others. The chief Precipitatory Liquor, is the Salt of Tartar, or of Herbs burnt to Aſhes, deliquated or melted; for this ſtrikes back the Particles of every ſoluted thing whatſoever, and ſends them headlong to the bottom; to wit, foraſmuch, as it paſſes through every where, the little ſpaces of the ſolvent, and ſticking to the Contents, increaſes them in bulk, that they more eaſily fall out of the pores of the *Menſtruum*, bound alſo together with their own weight.

What fluid Salt (as Vinegar, Stygian Waters, *&c.*) diſſolves, the ſame a fixed Salt precipitates; and on the contrary: becauſe Salt of Tartar being melted, moſt excellently penetrates common Sulphur, and receives the Tincture; which then is precipitated by a fluid Salt, *viz.* by the Spirit of Vitriol, and the like: which indeed does not happen, by reaſon of the diſagreeing Particles of the Salts, and mutually oppoſing one another; but for that the ſame are greatly of kin, and ruſh into mutual Embraces: for from hence, the little grains of the thing ſoluted, by reaſon of the cohering of both the Salts together, being increaſed in bulk and weight, are more readily thruſt out of the little ſpaces of the *Menſtruum*, and deſcend to the bottom. We will in this place, more ſparingly inſiſt upon inſtances of this nature, becauſe the more full handling of them belongs to the Chymical Work.

Precipitation is not only obſerved in the ſeparation of a more thick matter, from a ſerous *latex*, and in the ſetling of the diſturbed parts towards the bottom; but ſometimes the Particles ſhut up within the pores and paſſages of the Liquor, are ſo ſmall and ſubtil, that being Precipitated, they are not diſcerned by the ſight, neither do they quickly deſcend to the bottom; but from their ſituation and poſition, being variouſly changed, the colour, and conſiſtency of the Liquor, are diverſly altered. I was wont in times paſt, to ſport with the Solutions of Vegetables and Minerals, which being made by themſelves, were clear, like Spring Water, and appeared bright, being commixed, ſhewed now a Black colour, now a Milky, Red, Green, Blue, or ſome other kind. The Solution of Saturn, (or Lead) being made with diſtilled Vinegar, appears bright like common Water, if you add to this Oyl of Tartar, like clear Water, the mixture ſtraight grows White, like Milk. If Antimony calcined with Nitre, be boiled in Spring Water, the ſtraining ſeems clear, and almoſt without ſmell, which yet being daſhed by any Acid thing, preſently acquires a deep yellow colour, with a moſt wicked ſtink. Common Water fleing imbued by an infuſion of Mercury ſublimate, is preſently tinged with yellowneſs, by Oyl of Tartar dropped into it. Quickſilver, and *Sal Armoniack*, being beaten together, and ſublimated in a Matrace, by the heat of Sand, go into a white powder; this being ſoluted by melting, ſhows like to clear Spring Water, which yet being ſmeared upon Braſs, or Copper, appears like Silver; and being lightly rubbed on braſen Veſſels, renders them as if they were perfectly ſilvered. A Solution of Calcined Tin, being put to melted Salt of Tartar, becomes bluiſh. A clear infuſion of Galls, being mixt with a ſolution of Vitriol, makes Ink; if you add to this, Spirit of Vitriol, or Stygian Water, the black Liquor is by and by made clear, like Spring Water; and this Oyl of Tartar reduces again to Ink. And what is more wonderful, if you write on Paper with the clear infuſion of Vitriol, and frame any Letters; what you ſo write preſently vaniſhes, nor is there any marks of the Characters left: but if you ſmear over the Paper with an infuſion of Galls, preſently the Letters may be read, if wrote with Ink; which yet, with a Pen run over, dipt in Spirit of Vitriol, you may put quite out at once wetting, and then again render them, with wetting them with another Liquor of Tartar. The Sky-colour Tincture of Violets, being daſhed with Oyl of Vitriol, becomes of a Purple colour: to which, if you add ſome drops of the Spirit of Harts Horn, that Purple colour is changed into Green. *Braſil* Wood, being infuſed in common Water, leaves a very pleaſant Tincture, like to Claret Wine; if you pour to this a little diſtilled Vinegar, the Liquor appears clear, like White Wine: a few drops of Oyl of Tartar reduces it to a deep Purple colour: then if the Spirit of Vitriol be poured in, it becomes of a pale yellow, like to Sack; if you add the Salt of Lead, being ſoluted by deliquation, the mixture grows preſently Milky: by this means you may imitate that famous Water-drinker, who having ſwallowed down a great deal of Spring Water, was wont to vomit forth into Glaces placed before him, diverſly coloured Liquors, reſembling

the

the *Idea's* of divers kinds of Wines: for Glaſſes being medicated with the aforeſaid Tinctures, (ſo lightly that they may not be perceived by the ſtanders by) will not only cauſe the Water poured into them, to imitate every Wine, but will exhibit the very *Proteus* himſelf of the Poets, changed into Waters, and from thence putting on all colours, and infinite forms.

If a Reaſon of theſe kind of appearances be asked, it ought to be ſought in the minute Particles, contained within the pores of every Liquor; which as to their ſite and poſition, being diverſly altered, by another Liquor infuſed, tranſmit variouſly the Rays of Light, many ways break or reflect them, and ſo make divers appearances of colours. For when the Rays of Light paſs through almoſt in right Lines, they make a clear colour, like Spring-water; but if in their paſſage, they be a little broken, the Liquor grows yellowiſh; but being more refracted, they cauſe a red colour; if they are bowed back, ſo as to be drained, or that they cannot ſhew themſelves, a dark or black colour ariſes; but if they are again reflected, to the outmoſt Superficies of the Liquor, they create the image of Whiteneſs: after this manner we might variouſly Philoſophiſe about other colours, and their appearances, the diverſity of which, and ſudden alterations in Liquids, depend chiefly on Precipitation: becauſe, as the Particles contained in the Liquor, are driven ſometimes more near by another infuſion that they claſp themſelves together; ſometimes are ordered into other ſeries of poſitions, the diverſe repreſentation of colours is made. For Liquor being impregnated with little Bodies or Atoms, or this Nature, moſt minutely broken, ſeems as an Army of Soldiers placed in their Ranks, who now draw into cloſe Order, now open their Files and Ranks, now turn to the left, now to the right hand, as is diverſly ſhown in the exerciſing of Tacticks, or the Art Military. When two clear Liquors being mixed together ſhall make Ink, it is becauſe the Particles contained in either, approach near one another, and as it were placed in their cloſe Orders hinder the paſſage of the beams of light: when afterwards, this Ink is made clear by another Liquor poured in, it is becauſe the new Bodies of the thing put in, diſperſe abroad the former cloſe joyned Particles, and drive them as it were into their open Orders.

Chap. XII.

Of the Motion of Fermentation, as much as it is to be obſerved in the Coagulation, and the Congelation of Bodies.

Coagulation and Congelation of Natural Bodies, no leſs than their Solution, depend only on theſe our Principles. The improportionate mixture of theſe, and the exaltation, and powerfulneſs of ſome above others, are the cauſe of either. Spirit and Sulphur being looſned from the bond, do not only pull aſunder the proper Subjects, but they ſet upon whatever is next them; and where they are mighty in number and ſtrength, they affect nothing more than divorces and ſeparations from the reſt of the Principles, and ſuffer no delay: but on the contrary, Salts love to be united to the reſt, and to be made into hard and ſolid ſubſtances; and being deſtitute of the Company of the reſt, preſently to enter into new Friendſhips, and deſire only not to be joyned to any oppoſite. If at any time they are more impetuouſly moved, either by their own diſpoſition, or being ſoluted, they deſtroy the ſubſtance of others, this thing ſeems to be done for this end, deſtinated as it were by Nature, that they might find out ſubjects agreeable to themſelves, and having through War obtained Peace, they might at length be more ſtrictly united unto them: wherefore when ſaline *Menſtruums* corrode Stones or Metals, they are Coagulated with their Particles, and grow together into diverſly figured Cryſtals.

When we here treat of Coagulation, we do not take this word after the uſual manner: to wit, as it is wont to be vulgarly uſurped, when Milk is become congealed, that is, departs from its ſimple and equal Liquor, into Heterogeneous ſubſtances, *viz.* Cheeſe, or Curds and Whey, or thick and then; in like manner, when Blood or other Humors go into parts after that manner, they are ſaid to be coagulated: alſo, we have elſewhere given this ſenſe, to this word, tho' to ſpeak properly, theſe ſort of motions ought rather to be referred to Precipitation than to Coagulation. But here we would have to be underſtood, by the term Coagulation, an alteration in Bodies of the ſame kind, as when things at firſt tender and ſoft, grow hard, into a ſtiff, and as it were ſtony matter: or any thing is ſaid to coagulate, when ſaline little Bodies being diſperſed abroad in any ſubject, begin to be congregated and joyned

 together,

together, and from thence united, either among themſelves, or with Earth, produce out of a ſoft and fluid ſubſtance, a hard and compacted. This may be perceived in the ſhells clearly ſtony, of Fruits and Seed; in Bones and Horns of living Creatures, in ſhells and ſhelly ſcurffs of Fiſhes; all which indeed very much abound with an Alcali Salt, or the ſame Volatilized. Among Handicrafts, or Preparations from Human Induſtry, the Cryſtaliſation, Vitrification of Salts, or making of Glaſs, alſo the baking of Pots and Earthen Ware, ought to be referred to Coagulation.

But it is properly called Congelation, when the Saline Particles, coming from elſewhere, ſtrictly bind together the ſubjects on which they fall, fix the Particles variouſly moved within the ſubſtance of the mixture, and gather them together, that by that means the whole becomes ſtiff, and as it were ſtony. We may behold theſe kind of effects in Ice and Froſt, by which ſoft Mud, or fluid Springs of Waters grow ſtiff, into a very Marble ſubſtance. Alſo the ſame is manifeſtly beheld, among the Operations of Art, in the confuſions of ſome Salts, and mutual Concretion in Sublimating; by which means, they go into a ſubſtance, now like to Ice, now to Snow. To which may be added the Artificial turning of Water to Ice, which is performed by the mixture of Salt and Snow; but the inſtances which we have remarked in either of theſe, about the Works of Art, we will in this place briefly run through, and a little conſider the reaſons of them, and the ways of being done.

The Cryſtaliſation of Salts, is procured after this manner; Salts of every kind are throughly diſſolved in common Water, and their Particles being diſperſed through the whole Maſs of the Liquor, wholly diſappear; afterwards, if this Liquor be ſomewhat evaporated, that its paſſages and pores be ſomething bound together, the little Bodies of the Salt cloſe one with another, and mutually take hold of themſelves, and joyn together, the outward cold binding them, and are figured in the midſt of the Water, into Cryſtals proper to their Nature. By this means *Sal* Nitre into Pyramids, Sea Salt into Cubes, Alum into eight cornered Figures, *Sal* Armoniack into ſix cornered, and other Salts are formed into other Figures of their own accord, after a conſtant manner.

If the Reaſon of this be ſought after, we ſay that theſe kind of Salts are not ſimple Elements, but Bodies made up of abundance of Salt, with the other Elements mixed with them in ſmall quantity; which even as other Natural Concretes, are allotted by the firſt Creator, peculiar manners of figurations, according to the ſurpaſſing ſtrength of Salt and Spirit, and commixion with the reſt. For in determining the Figures of Natural Bodies, Spirit and Salt are as the Rule and Compaſs in deſcribing Mathematical Figures: Spirit, as the moveable Foot of the Compaſs, or as a Penſil in the hand of an Artiſt, variouſly excurs and draws here and there diverſe faſhioned lineaments. But Salt (as the applyed Rule) moderates the excurſions of the other, and determinates them, and reſtrains them within the confines deſigned by Nature: when the Spirit is more powerful than the Salt, there happens a greater variety in the Figuration of things, as in Vegetables and Animals; becauſe the Spirit running forth more largely, forms very many Marks of its Pourtracture, and deſcribes Bodies not in right Lines, but intorted, and very much variegated. Where the Salt lords it over the Spirit, as in Mineral Concretes, and chiefly ſaline; Bodies grow together in leſs adorned Figures, and are accounted the firſt and more ſimple, and of that ſort, as the Mathematical deſcriptions in right Lines or Circles. For thoſe Salts, are as it were ſecond Elements; and from the implanting of them in Bodies, the proper and native Figures of things, very much depend; and therefore they themſelves are primitively imbued by Nature with a certain Elementary Configuration, (ſo that according to *Plato*, God in truth exerciſes Geometry) and the firſt regular Figures are formed in the more ſimple, that things compounded of them, might ariſe furniſhed with all manner of variety of figures.

The fixed Salts of Herbs being prepared by Calcination, becauſe they are almoſt deſtitute of the Fellowſhip of Spirits, do ſcarce go at all into Cryſtals, nor are they coagulated, but by a long evaporation. Sea Salt containing a very little Spirit, with great Labour goes into Cubes. Next to this Alum, gifted with a little more Spirit, is more eaſily coagulated, and grows into more elaborate Figures, *viz.* eight cornered. *Sal* Nitre, ſwelling with ſpirit, is moſt eaſily coagulated, and is framed into a more perfect Figure, *viz.* Pyramidical; which conſiſts of both ſpherical, and right Lines. But Volatile Salt, (ſuch as is diſtilled out of Urine, Blood, and the Horns of living Creatures) being aſſociated with a plentiful Spirit, is drawn into Concretes, very much varying, which imitate now the Horns of Staggs, now the Figures of Plants. Out of Mercury, with Salt, or the Calx of Silver, by an Amalgama, in the midſt of the waters a Silver Tree is formed, with Stock, Trunk and Branches, painted to the Life. It is a uſual thing in the Winter-time, for the Air, impregnated with ſaline Vapors, and fallen on the Glaſs Windows, to be condenſed into moſt fair Figures of Trees and Woods. So much for the Cryſtalliſation of Salts: The other Species of Coagulation, is Vitrification, of which we will ſpeak next.

Vitrification

Vitrification (which is alſo ſaid to be the laſt mutation of Bodies, of which Nature is capable, and from which there is no going back) depends upon a fuſed Salt, and united to an Earthy Matter, even to its ſmalleſt Particle: for when either Matter is fuſed, by a moſt vehement fire, and divided in its ſmalleſt parts, the Bodies of either, being put into a Flux, are by ſo ſtrict a marriage joyned together, that afterwards they are never to be pulled aſunder.

There are many ways, and diverſe proviſions of Vitrification; to wit, of *Sal Alcali*, with Sand or a ſandy matter fuſed together by a violent Fire, common Glaſs is made; which is tranſparent, both by reaſon of the abundance of Salt, and of the clearneſs of the Sand; for if you behold the little Sands of which Glaſs is made, with a Microſcope, each of their little Globes appear, (as they were Glaſſie Gems) clear and ſhining. Wherefore Salt promotes the fuſion of that clear matter by fire, and then is admitted into its moſt ſtrict embraces being fuſed.

Beſides Glaſſes of diverſe Colours and Conſiſtences are made of Minium, the Calx of Tinn, Antimony, and ſome other Minerals, (when the ſulphureous part doth firſt fly away) fuſed, now by themſelves, now with Flint or Sandy matter. The reaſon of all which conſiſts in this; that Salt and Earth, being moſt ſmally broken by a violent fuſion of fire, and being divided as to their laſt Particles, catch hold of one another, and ſo are bound together, by the moſt ſtrict bond of the mixture. The Coalition or Coupling of theſe, is never to be diſſolved, becauſe there is wanting within in the mixture, other Principles, which might unlock the frame of the ſubject: yea, Salt and Earth, being joyned by the mediating fire, do ſo intimately cohere, that they affect not divorces of themſelves, nor ſuffer them from another.

The baking of Earthen Pots and Bricks, is of kin to Vitrification (or making of Glaſs) whereby moiſt and ſoft Clay is ſtifned into a very ſtony hardneſs: But in theſe, there is greater plenty of Earth, and leſs of Salt; wherefore they are leſs brittle, and not tranſparent. Concerning theſe we ſay, that by the fire mediating, and as it were handying the ſmalleſt, broken, and divided Particles of Salt, are married to every Particle of the Earthy matter, and with them grow hard, into as it were a ſtony ſubſtance, and that not eaſily to be reſolved. Alſo in theſe kind of matters, prepared by human Induſtry, we imitate indeed, with an excellent Artifice, the Concretions of Bones and Stones, made by Nature in divers Families of Animals, Vegetables, and Minerals.

As to what reſpects Congelation; Salts of a diverſe kind, do often meet together, and grow ſtiff, into as it were a new ſubſtance: But this happens many ways. Of theſe, ſome Salts being mixed together, preſently grow together into Cryſtals: for the Acid Spirits of Minerals being added to the Salts of Tartar, or thoſe made of the incineration of Vegetables, turn into a white Coagulum, like Snow, and with a ſpumeous or frothy Heat: The reaſon of which is, that the Particles of the Salt, having gotten a Flux, take hold of other Salts in the Spirit, Alcaliſate by melting; but by reaſon of the firſt Particles of either, being made unlike, there ariſes a ſtrife; then from the ſame confociate in one, that white ſettlement is made.

Not unlike the ſame manner, theſe Acetous Spirits, to wit, of Vitriol, Nitre, Salt, and others being mixed with Metals, while they corrode them, are Cryſtalliſed together with their ſaline Particles: ſo the Spirits of Vitriol, Nitre, alſo Stygian Waters, (which are only Salts having gotten a Flux) are formed into moſt elegant Cryſtals, in the diſſolving of Silver, Iron, Copper, and other things. For Salts, even as Sulphur, being looſned from the mixture, diſſolve other mixtures, and greedily deſire to be united with the Homogeneous Particles of the ſame ſubject.

There is another manner of Congelation, when Salts being mixed with ſome other matter, are elevated by ſublimation out of their ſubjects, and then congeal the Particles of that new matter, which they carry away with them, and grow together with them (like a Meteor) on high: after this manner the Salts of Vitriol, Nitre, and Sea Salt, being ſublimated with Mercury, are congealed as it were into a ſnowy ſubſtance: The ſame being ſublimed with Antimony, go into a matter like Ice. After this manner the Natural Congelations, by which ſome Minerals, and chiefly Vitriols and Sulphurs, are begot in the Bowels of the Earth, may be imitated. For of Iron and Copper are prepared factitious Vitriols, which are very like the Natural: Of Antimony Sulphur is made, which anſwers to an hair our common Sulphur in taking fire, colour and ſmell: For example, Pour Oyl of Vitriol, to the height of a finger's breadth, upon pulveriſed Antimony; and let it be diſtilled in a Retort in a Sand Furnace, a yellow Sulphur will be ſublimed in the Neck of the Retort, that cannot be diſcerned from the common Sulphur: which is a ſign that the Concretion of Sulphur is made in the Earth, when ſome ſulphureous Mineral is corroded by the Salt of Vitriol, whoſe ſulphureous parts are congealed by the ſame Salt. This alſo is an Argument, that Oyl of Sulphur, which is ſeparated, by inkindling under a Bell from the ſulphureous matter, is nothing elſe but Vitriolic Salt, nor doth any thing differ from Oyl of Vitriol.

Artificial Congelation concludes Inſtances and Examples of Congelations: to wit, whereby common Water, or any Liquors being put over the fire, or in an Hot Houſe, are ſuddenly congealed into Ice: 'tis a common way, and vulgarly known. Salt being mixed with Snow and Ice, and agitated or ſhaken in a Veſſel put into Water, ſuddenly the Water about the ſides of the Veſſel will be frozen. This will be done, if you make tryal of it, either with common Salt, or Sea-Salt, Nitre, or alſo with Vitriol, Alum, *Sal Armoniac*, or Mercury ſublimate: For Salt of every kind, being put to Snow or Ice, looſens their mixtures, and ſends away the Nitrous and Congelative Particles from the ſubjects; which preſently being immerſed in the neighbouring Water, congeal it, as if they were freſhly blown from the North.

What is more admirable; let a Diſh with Snow be placed over hot Coals, and in the middle of the Snow put a Glaſs full of Water: as the Snow is melted by degrees by the fire, the Water ſhall be frozen: for the Nitrous Particles, being driven away by the heat, by their departure, they are daſhed againſt the neighbouring Water, and congeal it.

And thus much for FERMENTATION in general, and briefly of its various parts; it had been almoſt an infinite Labour, and from our purpoſe, to heap up Inſtances in ſo diffuſe a thing. Thoſe hitherto brought, however choſen out of Natural Philoſophy, were fit to wait upon the following Medical Diſſertation, that we may more happily know the Original, Progreſs, and State, as alſo the Remedies and Cure of Motions, and Mutations, in Cauſes, which variouſly happen to all kind of Bodies, and ſomewhat reſpecting the Tumults, which from thence are begot in the human Body, from the Blood being irritated, and the reſt of the humors; to which exerciſe, God willing, we will now proceed.

FINIS.

THE PREFACE TO THE Treatiſe of Feavers.

To the Friendly Reader,

TO *Inſtitute in this Age a new Doctrine of Feavers, may perhaps ſeem the ſame thing, as if any one ſhould go about to deſcribe the midſt of our Country, for a Land before unknown. For what reſpect the* Diagnoſis *of this Diſeaſe, ſeem to be firmly Eſtabliſhed already, by the Precepts and Practice of the Antients and Moderns; yea, by long Experience, they are ſo generally in the mouth, and known of all Men, that nothing can be more. However I deſerve pardon, if I a little receed from the Vulgar Opinion concerning Feavers, as a way mightily worn out; and go on in a leſs trodden Path; becauſe I am not the firſt, or only Man that directs his courſe againſt the received Opinion, as againſt a Stream. For in truth, in the Medical Art, (and that deſervedly) thoſe things have not pleaſed the Men of our Age, which did thoſe of the former: becauſe the Antients relying on a falſe Poſition concerning the Motion of the Blood, proceeding as it were through ſlippery and moiſt places, often fell foully and dangerouſly: wherefore it is no wonder, if thoſe who come after ſhould take care for the thorough Inſtauration of Phyſick, and for the Re-Edifying the Building, (as they ſay) even from the Ground, the Antient Props being fallen down, on that which our moſt Famous* Harvy *hath laid, the Circulation of the Blood, as a New Foundation in Medicine But in this Work, Learned Men of other Countrys, but chiefly of our own, have happily laboured, not only in removing the Rubbiſh of the former Building, but for the ſupplying this plenfully with Stone, Planks, and other Matter. In times paſt, among the Antients, as the Diſtribution and Natural Motion, of the Nutritious Humor, of the Blood and Nervous Juice; ſo the Feaveriſh Heats, and Preternatural Motions of them, were wholly hidden and lay in the dark: but now new Lights have ſhined forth, and it is granted us to know the Cauſes of things before hidden, it doth not become prudent Men, and profeſſing Philoſophy, even to ſhut their Eyes and remain blind in the Light it ſelf; but eſpecially about a Diſeaſe by which the third part of Mortals have ſtill fallen to this day, to be rather willing to Err with the Antients, than to underſtand the Truth with the Moderns, or to believe what is more likely, argues a mind guilty of notable ſtubbornneſs. When therefore the Puretology, or Feaver Tracts of former Medicine, had no firm and ſtable Baſis, and that it is eaſie to ſhew that it was built upon very many, and plainly falſe Errors, what ſhould hinder, but that we having gotten more certain Principles, ſhould endeavour to erect a better Science coucerning Feavers? Truly I think it would hardly be, altho' the Pleas of the Antients, ſhould be yet openly maintained in the Schools, but that many Phyſicians, who have a mind to look within the Bark, would frame new Hypotheſes to themſelves from their own Ratiocination, by which they might more exactly quadrate the Phænomena of Feavers, than by that of the Antients. But it may be objected, that Feavers have been happily Cured by the ſame Remedies, and the like Method of Curing, from the times of* Hippocrates *and* Galen, *even to our days; and therefore it may ſeem a raſh Work, and little ſafe, that we ſhould endeavour new things, after having had the Experience of ſo many Ages, eſpecially ſince it is about the Human Body.*

Body. To this it will be eaſie to anſwer, that Medicine was at firſt Empirical, and Remedies were not invented by general Precepts, or by Rule, but by the frequent trial of ſeveral things: And if led by the Example of Hippocrates, *his Followers had only poliſhed his Obſervations and Experiments, without doubt the Medicinal Art had grown up better, more handſomly, and with greater benefit to the Sick. But that the Light, clearly inkindled by the Antients, did ſo ſuddenly ſhut up, and darkned the Eyes of Poſterity, it was, the prepoſterous ſtudy of thoſe, who too haſtily framed, almoſt out of their own Brain, Phyſick into a general Method, after the manner of ſome Speculative Science: for by this means, before they had laid a firm Foundation, a ſufficiently ſpecious, and deceitful Pile of unſtable Doctrin was erected. That therefore in the Cure of Feavers, ſome Indications being more antiently received, remain yet confirmed, and are to be perpetually obſerved, is to be aſcribed wholly to Experience, the firſt Miſtreſs of this Art, and not to the Precepts of Scholars. And from hence, I hope for my ſelf, to have gotten a defence ſufficient enough; for if the Opinions wholly erroneous of the Antients, had not hindered, but that the Practice of Medicine, at firſt inſtituted by a certain induction of obſervations, had proceeded commodiouſly enough; the Theory being joyned with Truth, would have brought much leſs hurt to the Sick; or have leſs carried away thoſe exerciſing Medicine, quite contrary from that Path, which Antiquity had left commended to us. In the mean time, 'tis not to be diſſembled, that naked Experience, without the helps of Method and Reaſon, avails little, yea very often doth much hurt; for neither are the ſame Diſeaſes, every where to be driven away by the ſame Remedies. But he ſeems to have hit the mark, who joyns both together, that Reaſon may not pervert Experiments, and Nature it ſelf, not that this may remove Reaſon from its place. Altho' that I know well enough, I have not obtained it, yet I will freely profeſs, that I have aimed at this Mark; and perhaps I may have deſerved ſome praiſe, even in failing in theſe ſort of Adventures; for after I had not found in Books, what might ſatisfie a mind deſirous of Truth, I reſolved with my ſelf, to ſearch into living and breathing Examples: and therefore ſitting oftentimes by the Sick, I was wont carefully to ſearch out their Caſes, to weigh all the Symptoms, and to put them, with exact Diaries of the Diſeaſes, into Writing; then diligently to meditate on theſe, and to compare ſome with others; and then began to adapt general Notions from particular Events: and when by this means, for a long time, obſerving the Accidents and Courſes of Feavers, I had buſied my ſelf, for the finding out forms of Reaſons for their Cure, at length a new Pathology of this Diſeaſe was conceived in my mind; which afterwards, by the frequent increaſing Concourſe of Obſervations, as it were the Juice and Blood, was formed by degrees into a Child, ſuch as it now appears. But the Infant, which I had ordered to be kept cloſely, in our private houſe, being remarkable for Paradoxes, as it were a monſtrous ſhape, the importune diligence of Friends has taken care to bring abroad, being gotten forth of my hands, and to be publickly beheld. What therefore is there ſaid concerning Feavers, beſides the common manner, I would not have any one eſteem it brought forth by me, as from a Doctor in the Chair: doubting, I bring theſe thoughts into Publick, and ſubmit them to the Examination and Emendation of the more Learned. That others before me have not ſpoken all things truly concerning this thing, ſhall be an Argument that I may Err, yea (if you pleaſe) that I have Erred: however, if I ſhould have rightly traced forth any marks, in this, at leaſt new ſearch of Truth; and ſhall have incited others (who are far better able) by this occaſion, to the full finiſhing of it; it will not repent me altogether of this, tho' raſh beginning.*

OF

OF FEAVERS.

CHAP. I.

The Anatomy of the Blood; and its Reſolution into five Principles: A comparing it with Wine and Milk.

HE Doctrine of Fermentation being explicated, it remains that we handle the chief Inſtance or Example of it, to wit, *Feavers*. For it ſeems that a Feaver is only a Fermentation, or immoderate Heat, brought into the Blood and Humors. Its Name is derived from *Februo* (or *Purgament*, which alſo is derived from *Ferveo*, to be Hot) which Word indeed is commodiouſly put to every *Feaver*; for that the Blood in this Diſeaſe grows hot; and beſides, by its fervor, as working muſt, it is purged from its filthineſſes. But that this Fermentation or feaveriſh Effervency may be rightly explicated, theſe three things are to be conſidered. Firſt, What the fermenting Liquor is; whether only Blood, or any humors beſides. Secondly, In what Principles in the mixture, and in what proportion of them this Liquor conſiſts. Thirdly, and laſtly, By what motion and turgeſcency of thoſe Parts or Particles, of which the Blood is made, the Feaveriſh Effervescency is ſtirred up. Theſe being thus premiſed, the Doctrine of Feavers ſhall be delivered, not from the Opinions of others, but according to the compariſons of Reaſons, picked (though from ours, yet) from diligent and frequent Obſervation, and confirmed by certain Experiments; all which however, I willingly ſubmit to the Judgment of the more skilful.

It plainly appears, even to the Senſe, that the Blood doth hugely boil up, and rage in a Feaver; for every one (though rude and unskilful) being in a Feaver, complains of the Blood being diſtempered, and of the ſame growing hot in the Veſſels, and as it were, put into a fury. Alſo, beſides the Blood raging in the Veins and Arteries, it may be lawfully ſuſpected, that that Juice with which the Brain and Nervous Parts are watered, is wont oftentimes to be in fault; for when this Liquor is ſeen to be carried back from the Blood, into the nervous ſtock by a conſtant motion, and certain Circulation, and from thence through the Lymphatick Veſſels, into the boſom of the Blood, it is probable, if by reaſon of a Taint contracted from the Blood, that humor be depraved in its diſpoſition, or is perverted from its equal motion, that from thence the Rigour, and Pain, Convulſion, Delirium, Phrenſie, and many more Symptoms of the Nervous kind, uſual in Feavers do ariſe.

After the Blood and Nervous Liquor, two other Humors, for that being apt to grow hot, fall into our conſideration, *viz.* The Chyme or nouriſhing Juice, continually coming to the Maſs of Blood, and the ſerous Latex, perpetually departing from the ſame, which, though they be the firſt and laſt Liquors ſeparated from the Blood, and diſtinct from it, yet being confuſed with it, they ought to be eſteemed as its aſſociate parts or complements; for the nouriſhable Juice being freſh brought, is accounted the crude part of the Bloud, and to be aſſimilated; and the *Serum*, it's ſtale part, and to be carried away. And after this manner, ſo long as either are circulated with the Bloud it ſelf, in the Veſſels they participate of the heats of the firſt begotten Bloud, and oftentimes occaſionally begin them, or increaſe them being begun; but by what means theſe things come to be be done, is declared hereafter in their proper places. As to the reſt of Humors, which are only the Recrements of the nutricious Juice, or the bloud, when they are included, either in their proper Receptacles, or conſtrained in the narrow ſpaces in the *Viſcera*, neither waſh the ſeveral parts of the Body with a continual luſtration, as the Bloud or Nervous Liquor, or the other Humors but now recited, are to be exempted from this Rank; ſometimes perhaps they may be the occaſional Cauſe that the Bloud doth conceive an undue Effervency, or that it perſiſts in it longer; but it is only the Bloud, (with the the Nervous Liquor, the alible Juice, and *Serum* Aſſociates) which

which boiling up above meaſure, with its heat, and ſtirred up with a rage through the Veſſels, diffuſes the preternatural heat, and induces the formal reaſon of the Feaver: but how this comes to be done, is not to be known plainly, but by a more near beholding the Nature of Blood, and as it were an Anatomy made of its Liquor.

There are in the Blood, (as in all Fermentative Liquors) Heterogeneous Particles, which as they are of a diverſe Figure and Energy, remain a long while in the mixture, by their mutual oppoſing one another and ſubaction, the motion of Fermentation is continually conſerved; as is perceived in Wine, Beer, and other Liquors: then, if the mixtion of the Liquor be ſomewhat unlocked by the adding of Ferments, the Native Particles being freed from their bonds, do yet more ſwell up, and induce Fermentation, with a more rapid motion and heat: which is ſeen in a familiar Experiment of the Chymiſts, *viz.* when fluid Salts are mixed with ſaline Liquors of another kind; from thence a great heat and ebullition are ſtirred up. Wherefore we ought to inquire concerning the Blood, of what Particles it conſiſts, that it ſhould be fit to Ferment, (as Wine, Beer, and other Liquors) of its own Nature: then by the help of what kind of Ferments, both its Natural and Feaveriſh heats are performed, with warmth, and a more quick motion.

The Maſs of the Blood, by the Opinion of the Antients, was thought to conſiſt of four Humors; to wit, Blood, Phlegm, Choler, and Melancholy: and it was affirmed, that according to the eminency of this, or that Humor, diverſe temperaments are formed; and that by reaſon of their fervors or exorbitances, almoſt all Diſeaſes do ariſe. This Opinion, tho' it flouriſhed from the time of *Galen*, in the Schools of Phyſicians, yet in our Age, in which the Circular motion of the Blood, and other affections of it were made known, before not underſtood, it began to be a little ſuſpected; nor to be ſo generally made uſe of, for the ſolving the *Phænomena's* of Diſeaſes: becauſe theſe ſort of humors do not conſtitute the Blood, but what are ſo called (except the Blood) are only the recrements of the Blood, which ought continually to be ſeparated from it: For in truth the Blood is an only humor; not one thing about the Viſcera, and another in the habit of the Body; nor is it moved at one time by Phlegm, and another time with Choler, or Melancholy, (as is commonly aſſerted) but the Liquor growing hot in the Veſſels, is only Blood, and whereſoever it is carried through all the parts of the Body, it is ſtill the ſame, and like it ſelf. But becauſe by reaſon of the abundance of the implanted heat in ſome, and becauſe of the ſmalneſs of it in others, the Coction of the Aliment is now quicker, now ſlower performed in the Bowels, and in the Veſſels; therefore the temper of the Blood (tho' but one, and always the ſame Liquor) becomes diverſe: and according to the various diſpoſition of this, it may be ſaid that men are Choleric, Melancholic, or of another temperament. Beſides, becauſe whilſt the Blood is made in its Circulation in the Veſſels, ſome parts continually grow old, and others are ſupplied anew, hence from Crudity, or too much Coction, there is a neceſſity that what is excrementitious ſhould be heaped together: which notwithſtanding by its efferveſcency, (as by the working or depuration of Wines it comes to paſs) it is ſeparated from its Maſs, *viz.* the watry humor, fixed in the Bowels, or ſolid parts, is it which is called Phlegm: ſome Reliques of aduſt Salt and Sulphur, being ſeparated in the Liver, and received by the Choleduct Veſſels are called Choler; the Earthy feculences being laid up in the Spleen, are termed Melancholy. In the mean time, the Blood if rightly purified ought to want Choler, Phlegm and Melancholy: even as when ſome Wines, or Beer are purified, the more light Particles are carried upwards, which conſtitute its Flowers or Head; and the dregs are preſt down to the bottom, which grow together into Feces or Tartar: yet none can truly ſay it, Wine or Beer is compoſed of Froth, Tartar, and a Vinous Liquor. But as theſe humors, commonly ſo called, are made out of the other Principles, *viz.* Choler out of Salt and Sulphur, with an admixtion of Spirit and Water; and Melancholy, out of the ſame, with an addition of Earth; and as the Blood is immediately forged out of theſe kind of Principles, and is wont to be reſolved ſenſibly into the ſame, I thought beſt, the common acception of humors being laid aſide, to bring into uſe theſe celebrated Principles of the Chymiſts, for the unfolding the Nature of the Blood and its affections. There are therefore in the Blood, as in all Liquors apt to be Fermented, very much Water and Spirit, a mean of Salt and Sulphur, and a little of Earth. The Blood being looſned by putrefaction, exhibits the ſame ſeparated and diſtinct. Alſo in the Blood contained in the Veſſels, or being freſh let out from them, we may diſcover their energies and effects: beſides, when in the Food, whereby we are fed, by the Juice of which the Liquor of the Blood is made, theſe ſame are implanted, no man will go about to deny that the Blood alſo is made from them: wherefore I will briefly run through theſe, and endeavour to ſhew by what means the Conſiſtency, the Properties, and the Affections of the Blood are made by them.

1. Spirits (which readily obtain the chief place) are a ſubtil, and greatly volatile portion of the Blood. Their Particles, always expanſed, and endeavouring to fly away do move about the more thick little Bodies of the reſt, wherewith they are involved, and continually detain them in the motion of Fermentation. The Liquor of the Blood continually boils up with their efferveſcency or growing hot, and equal expanſion in the Veſſels, and the reſt of the

the Principles are contained in an orderly motion, and within the bond of the exact mixture; if any Heterogeneous thing, or unagreeable to the mixture, be poured into the bloody Maſs, preſently the Spirits being diſturbed in their motion, rage, ſhake the blood, and force it to grow hugely hot, until what is extraneous, and not miſſible, is either ſubdued, and reduced, or caſt out of dores. By the irradiation, or rather the irrigation or watering of theſe, the Bodies of the Nerves are inflated, the Functions of the Viſcera, and alſo the Offices of motion, and ſenſation are performed: from the want of Spirits, alſo from their motion being depraved or hindred, ariſe great vices of the Natural œconomy or Government. The more quick motion and effervescency of theſe in the blood, (above what is in Wine) chiefly depends upon the Ferment of the Heart; becauſe, whilſt the blood paſſes through the Boſom of the Heart, its mixture is very much looſned, ſo that the Spirits, together with the ſulphureous Particles, being ſomewhat looſned, and as it were inkindled into a flame, leap forth, and are much expanded, and from thence they impart by their deflagration, a heat to the whole. By reaſon of this kind of expanſion, and ſuffuſion of heat, there is made a continual expence of Spirits, which being rarified, as it were inkindled, continually fly away, and are evaporated forth adoors: and as long as we live there is made a continual reparation of theſe by aliments, chiefly the moſt delicate; which contain in themſelves very much of Spirit and ſwelling matter: from which juice being drawn by digeſtion, and collated to the blood, is aſſimilated to it and fills up its defects. When the Blood of Animals is diſtilled, the Spirits (like *Aqua Vitæ*) aſcend of a limpid colour, they are made very ſharp and pricking, by the adheſion of the Salt; yet they are not ſo eaſily drawn off, as the Spirits of Wine, but that there is need of a more intenſe fire to force them, becauſe they are hardly driven from the fellowſhip of the thicker parts, with which they are involved.

2. That there is plenty of Sulphur in the Blood, it is plainly ſeen, becauſe we are chiefly fed with fat and ſulphureous Aliments, alſo the Nutriment from the blood, carried to the ſolid parts, goes into Sulphur and Fatneſs. It is moſt likely, from the diſſolution of this, that the red Tincture of the Blood doth ariſe: for ſulphureous Bodies, before any others, impart to the ſolvent *Menſtruum*, a colour highly full of redneſs; and when by reaſon of too great Crudity, the Sulphur is leſs diſſolved, the blood becomes watery and pale, that it will ſcarce dye a Linnen Ragg red. The Maſs of blood being impregnated with Sulphur, and together with Spirits, it becomes very Fermentable: which however, whilſt it enters the Ventricles of the Heart, there ſuffers a greater effervescency, or rather accenſion; and on the Particles chiefly ſulphureous, being inflamed; and thence diffuſed through the whole, the lively and vital heat in us depends. When the ſulphureous part is carried forth, and doth too much luxuriate in the blood, it perverts its diſpoſition from its due ſtate, that therefore the blood being either depraved, or made more bilous or Cholerick, doth not rightly Cook the nouriſhing Juice; or being inkindled throughout, it conceives heats and ardours, ſuch as ariſe in a continual Feaver. For the Sulphur being too much exalted; and ſwelling more than it ought, ſtirs up great heats in the blood: and they whoſe blood is more plentifully impregnated with Sulphur, are moſt obnoxious to Feavers. By reaſon of the Particles of this being incocted with the Nutritious Juice, and from thence carried to the ſolid parts, fatneſs, ſoftneſs and tenderneſs, come to our Body. From the Fleſh or Blood putrefying, by reaſon of the abundance of evaporated Sulphur, a moſt evil ſtink breaths forth: In the diſtillation of Blood, Sulphur aſcends under the form of a blackiſh Oyl, which alſo by reaſon of the Empyreuma, ſtinks moſt wickedly.

3. That Salt is in the Blood, is evinced by the Salt; which, tho' fixed, is drawn forth, by being eaten, from Vegetables, and from other eatable things, at firſt leſs volatile, afterwards by the moſt excellent digeſtion of Nature, and Circulation, is highly volatiliſed; that it paſſes through, not only without a remaining *Caput Mortuum*, all the members and parts of our Body, but alſo the blood being expoſed to diſtillation, aſcends the Alembic, and leaves the dead Head as inſipid earth: If at any time the ſaline Particles are not rightly exalted in the Blood, by reaſon of ill digeſtion, but remain crude, and for the moſt part fixed, from thence the blood becomes thick and unfit for Circulation, ſo that Obſtructions are begot in the Bowels and ſolid parts, and ſerous Crudities are every where heaped together: But if the Salt be too much carried forth, and ſuffers a Flux, the Spirit being depreſſed, or deficient, a ſour and bitter diſpoſition is given to the blood, ſuch as is obſerved in Scorbutical People, and thoſe ſick of a Quartan Feaver. Alſo from the Salt, for this reaſon being variouſly coagulated, the Stone, Kings-Evil, Gout, Leproſie, and very many other Chronical Diſeaſes ariſe. But when Coction being rightly performed in the Bowels and Veſſels, the Salt is duly exalted, and being aſſociated with the Spirit, is volatiliſed, then by reaſon of its mixture, the Liquor of the Blood more equally ferments; alſo is defended from Putrefaction, Stagnation, and Coagulation: Alſo the ſaline Particles, bridle the fierceneſſes of the Spirits, and eſpecially of Sulphur; wherefore, thoſe who have their blood well filled with a Volatile Salt, are leſs obnoxious to Feavers: alſo hence thoſe who often are let blood, are more apt to Feavers.

4. Beſides, There are in the Blood, (as it is a thick Humour, and hath a groſs conſiſtence) many Earthy Particles: from hence alſo, its too great Volatiliſation is as it were ſupported, and its too haſty accenſion hindered: even as Charcoal-duſt, is added oftentimes to Gun-Powder in a greater proportion, that all its parts may not take fire at once, and too ſoon. Further, from the Terreſtrial Particles of the Blood, and Nutritious Juice, the bulk and increaſe of the Body proceeds. Laſtly, from the diſtillation of the Blood, a light and friable *Caput Mortuum*, is left in great plenty.

5. Upon the watery part of the Blood depends its fluidneſs; for from hence its ſtagnation is hindered, and the Blood is circulated in the Veſſels, without growing thick or ſtiff: alſo its too great conflagration, and aduſtion is reſtrained, and its heat attempered. When Blood is diſtilled a clear and inſipid Water is drawn off, at leaſt in a double proportion to the reſt; for from hence the matter of Urin, Sweat, and every humid Excrement, for the moſt part proceeds.

What things were but now aſſerted, concerning the Principles of the Blood, and the affections to be deduced thence, will better appear, if we conſider a little the Blood, according to its ſenſible parts, and ſhall compare it with other Liquors which are in daily uſe amongſt us. Thoſe ſort of Liquors, which have a very great Analogy with the Blood, are, *viz.* Rich Wine and Milk. As to the Reaſons of Fermentation and growing Hot, it is moſt fitly compared to Wine; as to its conſiſtency, coagulation, and departure of the parts one from another, it is likened to Milk.

In the firſt place therefore, it is obſerved of Wine, that ſo long as it is ſhut up in the Veſſel or Pipe, its ſubtil and ſpirituous Particles, do perpetually agitate, or very much ſhake others more thick, break them, and render them fit for an exact mixtion; what is heterogeneous, and and unfit for ſubaction or mingling, is ſeparated by its growing hot: In the mean time the purified Liquor greatly fermenting, is in perpetual motion, whereby all the parts (as Atoms, variouſly moved up and down, in a beam or ſtreak of light) do ſtretch themſelves forth on every ſide, and contend with a conſtant rowling about, from top to bottom, and from thence to the top again. By the attrition and refraction of the Particles, very many *Effluvia* of Atoms, go away from the Liquor, which if the Veſſel being cloſely ſhut, they are kept within; the Liquor grows too exceſſively hot, and oftentimes cauſes the containing Veſſel to burſt in pieces. Blood, much after the ſame manner being ſhut up within the Veins and the Arteries, is urged with a conſtant Circulation: The Vital Spirit makes ſubtil, breaks, and exactly molds the more thick Particles; what is heterogeneous, and not mixable, it expels forth of dores; in the mean time by the refraction and kneading of the parts, *Effluvia* of heat do conſtantly ſtream forth, and evaporate through the pores; which being ſhut in, if tranſpiration be hindred, preſently by reaſon of the too great boiling of the Blood a Feaver is inkindled.

Secondly, We will obſerve concerning Wines, that they grow turgid, or ſwell up, if any extraneous thing, and of a Fermentative Nature, be poured to them; yea ſometimes, that they are moved more than ordinary of their own accord. For, when by a long digeſtion, the ſulphureous part of the Wine is too much exalted, it conceives a greater heat than it ought, and (unleſs preſently appeaſed) perverts the diſpoſition of the whole Liquor, with its ſwelling up. It ſeems to be for the very like reaſon, that the Feaveriſh heat which is wont to be introduced by reaſon of the ſame Cauſes, is ſtirred up in the Blood, as ſhall be ſhown in the next Chapter, where we treat of the Motion and Heat of the Blood.

The third Obſervation, or comparing of the Blood with Wine, ſhall be of this ſort: Wines (as alſo many other Liquors, as for example, Beer, or Sider) have their times of crudity, maturation, and defection. For when they are firſt made, the ſpirituous parts are ſo obvolved by the others more thick, that they ſhew themſelves but little, and put forth almoſt nothing of ſtrength or vertue: and as the other Particles, are not yet ſubtiliſed, nor truly concocted, the whole Liquor remains crude, and of an ungrateful taſte; and if put to diſtillation, not any Spirit aſcends. From this ſtate it comes by degrees to perfection, and when the Spirits being extricated from their intanglements, obtain their own right, and have ſubtilized and exalted the more thick Particles of the reſt, the whole maſs of the Liquor becomes Clear, Spirituous, Sweet, and Balſamick. Laſtly, When by a long Fermentation, the Spirits are conſumed, and begin at length to fail, the ſtate of defection is induced, whereby Wines, and other Liquors, either paſs into a taſtleſneſs, or at laſt the Salt and the Sulphur being too much exalted, are made ſowr or unſavory. In like manner the Blood alſo, while it is Circulated in the Veſſels, may be conſidered according to this kind of threefold diſpoſition: Firſt, in the making or crudity, which has relation to the Chyme new made in the *Viſcera*, and freſhly poured to the Blood; the Particles of which, like to unripe Fruit, are crude and undigeſted. Secondly, In the perfect ſtate or maturation, which belongs to the Blood being ſufficiently wrought, and made Volatile, according to all its Particles after it is inſpired by Ferments, and its inkindling in the heart exalted. Thirdly, In its defection, which reſpects the Blood; after it hath burned forth, and its ſpirituous parts are very much flown away, and the reſt growing old and poor, have need to be removed; and ſo they are either

either the Reliques of Salt, which are with the *Serum* ſtrained forth continually by the Urine; or they are Particles of Salt and Sulphur, boiled and baked together, which are ſtrained forth by the virtue of the Liver into the choleduct Veſſels: or laſtly, they are dregs and earthly recrements of the Blood it ſelf, which are carried into the Spleen, and there (as it were a *Caput Mortuum*, exalted by a new digeſtion) go into a Ferment, at length to be tranſmitted to the Blood. Whilſt after this manner, the generation of the Bloud, and its due maturation are truly diſpatched, it is pleaſingly circulated within the Veſſels, neither wanting in motion or heat, nor inordinately troubled with them. But if either the ſupplement of the nouriſhing Juice, be not made agreeable with the reſt of the Bloud, nor aſſimilated with it, but that either by reaſon of the defect of Concoction, it is waſhed into a very crude humour, or becauſe of its exceſs, it is roſted into a burnt matter; or if the Bloud growing old, does not lay aſide what it caſts off, and give way to a new nutritious Humor; I ſay, by reaſon of theſe kind of Vices, concerning Sanguification, or the making of Bloud, the Bloud is variouſly perverted from its due temper and equal motion, and now becomes watery and cold; now ſharp or ſalt; now acid, auſtere, or by ſome other way degenerate; and ſometimes obnoxious to ſtagnations, and ſometimes to immoderate heats.

We may obſerve theſe kind of degrees of Crudity, Coction, and Defection in the Bloud, both of the ſound and of the ſick; in healthful perſons after a more plentiful Repaſt, Surfeit, or hard Drinking, when too much of *Serum* or of Juice, is poured to the Blood, its whole Maſs being too much diluted with a crude humor, becomes more watery, and leſs ſpirituous; wherefore men are rendred ſluggiſh, and unfit for motion or exerciſe. In ſick perſons the Phlegmatic Conſtitution of the Body, induces ſuch a crudity of the bloody maſs, as is diſcerned in the white Dropſie, the Dropſie, *Pica*, or longing Diſeaſe, and the *Chloroſis*, or Green Sickneſs. Alſo the ſtate of this kind of crudity, comes in an intermitting Feaver, and in truth is the cauſe of the Feaveriſh acceſſion, *viz.* by reaſon of the dyſcraſie of the Bloud; the nouriſhing Juice being heaped up, is not aſſimilated to it, but for the moſt part goes into a crude, or otherwiſe degenerate matter; with which, when the Maſs of Bloud is filled to a plenitude, ſwelling up, it brings on the Fit.

The ſtate of Maturation, concoction being finiſhed, happens in healthful perſons, ſome hours after Eating, eſpecially in the morning, to wit, when the ſupplement of the Chyme is ſpiritualized, and as it were enkindled in the whole, by reiterated Circulations; for then men are made more nimble and lively, and more ready for ſtudies, or any buſineſs.

The ſtate of Defection is in the blood of ſound men after faſting long, hard labour, and want of Food; for then the Vital Spirit being very much evaporated, the maſs of the Blood begins to become as it were lifeleſs, wherefore they preſently languiſh, and are made weak. Moreover, the blood by a too long coction is burned, and grows bilous, from whence thoſe accuſtomed to want Food, or faſting, for the moſt part become ſad and melancholic. Some Diſeaſes habitually induce ſuch a diſpoſition of the blood; ſuch are the Scurvy, the yellow Jaundies, the Cachexia (or evil ſtate of the body when the nouriſhing Juice turns to ill humors) long Feavers, and moſt Chronical Diſeaſes, in which, the whole maſs of blood paſſes from a ſpirituous, into either a ſowr, ſharp, or auſtere Nature.

So much for the comparing of bloud with rich Wine; what follows, being a ſimilitude of it with Milk, conſiſts in the diverſity of the parts, and their ſetling apart, which is chiefly ſeen in its being let forth from the Veins, and grown cold in the Diſh. For when the heat and vital Spirit, which conſerve all things in the mixture, are flown away, the remaining parts depart from one another of themſelves, and a ſeparation of the thin from the thick, and of the *Serum* from the fibrous bloud is made. This ſort of ſeparation of the parts, ſucceeds almoſt after the ſame manner, as in the coagulation of Milk. There are in Milk, Buttery, Cheeſie parts, and Whey. The like is in blood, ſo long as it doth not much recede from its natural temper: for it is good, when being let forth of the Veins, it grows cold in the Porringer, its parts do ſettle after the ſame manner; to wit, the more pure portion, and ſulphureous (like Cream) comes together on the Superficies, which in healthful people, looks brightly red, and this anſwers to the flowering or head of the Milk: under this lies a purple thick ſubſtance, which conſiſts of little Threds and Fibres joyned together, and as it were concreted into a clotty ſubſtance or parenchyma, ſuch as the Liver: For the heat being conſumed, and the bond of the mixture looſned, the Fibrous parts lay holdon one another, and by their weight, ſettle into a more thick Coagulum, which anſwers to the Cheeſie part of the Milk: In the mean time, the Serous or Wheyey parts, being thruſt forth from the reſt, get their own Nature, and conſtitute a clear Liquor, like water; which as it is thinner, aſcends to the top, and ſwims upon the reſt. Further, as the Whey of Milk is wont to be further coagulated, and doth yet contain in it ſelf ſome parts both Buttery and Cheeſie; ſo this Liquor ſwimming on the Blood, if it be expoſed either to the fire, grows thick, like the White of an Egg a little roſted, or if an acid Liquor be powred to it, it will be precipitated into a white Coagulum. This being ſeen, ſome have thought this watery Latex, to be the nouriſhing Juyce, which imparts nouriſhment to the whole Body, from the maſs of

the blood, in the time of its Circulation, and that the reſt of the blood is only the Vehicle of Heat and Spirits, and ſerves for no other uſe. But to me it ſeems more likely, that in this watery Liquor is contained the nouriſhing Juyce, which is employed on the Nerves, and the commonly termed Spermatic parts, for nouriſhment is ſupplied to the Muſculous ſtock, from the fibrous blood of the Parenchyma, or the Liver, Lights and Milt. After this manner, blood being not much vitiated, goes into parts like Milk; but if it be exceedingly depraved, when it ſettles, it ſhews a far different diſpoſition, and as to its ſingle Contents, is allotted into various appearances; for the Cream growing together on the top, is ſeen to be ſometimes white, ſometimes green, now yellow, or of livid or Lead colour; alſo it becomes not tender, but very viſcous or clammy, that like a Membrane, it can ſcarce be pulled in pieces. When the blood long growing hot with a Feaveriſh Diſtemper, is let forth from the cut Vein, in its Superficies, inſtead of a Scarlet Cream, there grows together often a white Skin, or of ſome other colour; the reaſon of which is, becauſe the blood is throughly roſted, by two great Ebullition, and its more pure portion, as it were by a certain elixation, is boiled forth from a red and tender ſubſtance, to a white and tough; but if in the mean time the bloody maſs be not ſufficiently purged from the aduſt recrements of Salt and Sulphur, the colour of this little Skin becomes yellow or livid, and therefore the Water ſwimming over it, is often tinged by the ſame means. Further, the Purple Craſſament or thick ſubſtance is alſo various, *viz.* ſometimes it is of a blackiſh colour, when the blood is ſcorched too much, by a long effervescency. When the Fibres are vitiated, as in the Liver, they grow not together, but the Liquor like Beaſting Milk, remains ſomewhat thick, and yet fluid; which indeed argues a great corruption of the blood; as uſes to happen in a putrid Feaver, a very great Cachexy, ſometimes the watery Latex is wanting, as in Hectical people, and in too great a Diaphoreſis. Sometimes it ſuperabounds, as in Dropical people, neither will the whole go into a white Coagulum, by heat: In ſome Cachectical people, the blood being made more watery, appears like watered fleſh. I knew one endued with a vicious habit of Body, that was wont to have blood of a whitiſh colour, and like to Milk when it was let forth, and afterwards, when he grew better by Chalybeat Medecines, his blood was moderately red; but concerning the ſetling of the blood, and its appearances, there is enough. But as blood being emited from the Veſſels by its coagulation and departure of the parts one from another, imitates the various ſubſtances of congealed Milk, ſo ſometimes being ſhut within the Veins and Arteries, like ſome fuſed by a Coagulum, enters all together into the like mutation from Morbific Cauſes; by reaſon of which change, being hindred in its Circulation, or ſomewhere congealed and fixed according to its portions, it produces many Diſtempers: for it ſeems, that from hence the Pleuriſie, the Squinancy, the Inflammation of the Lungs, the Dyſentery, take their Original, and to this Cauſe the Peſtilent Diſeaſes ow chiefly their deadlineſs, as ſhall be ſaid hereafter in its place.

It is ſufficient that we have hitherto drawn a parallel of the blood, from which compariſon with Wine and Milk, may be gathered what ſort of Particles and Subſtances it comprehends in it ſelf, *viz.* Spirituous, and very agil or nimble (ſuch as generous or rich Wine has) for the heat and motion; and beſides ſoft and tender (ſuch as are in Milk) for the nouriſhment of the Body. Yea alſo, this Analogy of it with Wine and Milk, is yet further confirmed by the uſe of them in our Diet, out of which the blood is generated; foraſmuch as Milk is the beſt and moſt ſimple Aliment, and with it Infants, and Children, who have need of a plentiful proviſion of blood, are nouriſhed chiefly: But Wine copiouſly begets Vital Spirits before all other things, and being weak and fallen, excellently reſtores them; wherefore it is wont to be eſteemed inſtead of Nectar for old men, or thoſe of ripe years.

The Nature and Analyſis of the blood flowing within the Veſſels, being opened after this manner, the nutricious Juice deſerves yet our conſideration, being ſupplied from the blood, and ſeparated out of the maſs of blood, for the nouriſhment of the ſolid parts, and cleaving to them (whereby it may be the better aſſimilated) like Dew. For the Nerves, tendons and the reſt of the ſolid parts of the whole Body, are waſhed with a certain alible Juice. The Vital Spirits, having obtained the Nervous Bodies for a Vehicle of this, blow them forth at length, and expeditiouſly execute the actions of Senſe: alſo that Humor coming upon the ſolid parts, and aſſimilated with them, enlarges their Bulk and Growth. This is not a place to enquire after the Origin, Birth, and manner of the Diſpenſation of this: It ſhall ſuffice only that we have noted, that it is ſupplied from the maſs of blood, and (as it is rendred highly probable by the moſt Learned Dr. *Gliſſon*, and Dr. *Wharton*) after it hath paſt through the Nervous part by a certain Circulation, what remains, being now made as it were poor and lifeleſs, is ſent back by the Lymphatic Veſſels, to the blood. Whilſt this Juice, being little cocted, or purged from dregs, is ſent from the depraved blood, to the Nervous parts, 'tis wont variouſly to irritate them into Cramps and Convulſive Motions; alſo, no few Symptoms in Feavers, ariſe by reaſon of the depravation, and irregular Motion of this Juice, as ſhall be more largely laid open in another place.

CHAP.

Chap. II.

Of the Motion and Heats of the Blood.

So much for the Anatomy of the Blood, as to its primary Elements and conſtitutive parts, into which it is ſenſibly wont to be reſolved; alſo as to its Affections, which appear clearly, by the comparing it with Wine and Milk: it remains for us next to enquire concerning the motion of the blood, both Natural, *viz.* by the help of what Ferment, and by what ſwelling up of parts, it is Circulated in a perpetual motion through the Veſſels) and preternatural, *viz.* for what Cauſes, and what fury of parts, when it boils up above meaſure in the Veſſels, and conceives Feaveriſh Effervescences. Theſe being rightly unfolded and premiſed, we will enter upon the Doctrine of Feavers.

Concerning the Natural Motion of the Blood, we ſhall not here enquire of its Circulation, *viz.* by what Structure of the Heart and Veſſels, it is wheeled about after a conſtant manner, as it were in a Water-Engine; but of its Fermentation, *viz.* by what mixtion of parts, and mutual action of them together among themſelves (like Wine fermenting in the Ton) it continually boils up. And this kind of motion (as it were truly an inteſtine war of the Blood) depends both on the Heterogeneity of the parts of the Blood it ſelf, and on the various Ferments, which are breathed into the maſs of the Blood from the Bowels.

As to the firſt: thoſe things which have altogether like Particles, do not ferment, wherefore neither diſtilled Waters, Chymical Oyls, Spirits of Wine, or other ſimple Liquors are moved, as hath been already obſerved: but I have ſaid, that Blood, according to the Nature of things quickly irritable, doth conſiſt of a proportionate mixture of the Elements; in which Spirits, for that they are very nimble, continually ſtrive to expand themſelves and to fly away: but being entangled by the more thick Particles of the reſt, they are detained in their flight. And being detained after this manner, they toſs about, break to pieces, and very much ſubtilize the more thick little Bodies, by which they are hindred; they volatilize the Salt, otherwiſe fixed; by a moſt minute kneading, and by the adheſion of it, they perfectly diſſolve the Sulphur, compacted in it ſelf, and not miſcible with the reſt, and boil it in the *Serum*. They break the Earth, even to its ſmalleſt parts, and mingle it with the reſt. But in the mean time, by the ſtriking and molding the Salt and the Sulphur, *Effluvia's* of heat plentifully proceed, which being mixed with the reſt, and on every ſide diffuſed, increaſe the motion of the Fermentation. And after this manner all being moſt minutely broken and diluted with watery Particles, they conſtitute the Liquor of the Blood, , which whilſt in the Veſſels, as Wine ſhut up in a Pipe, continually ferments, and according to all its Particles is in perpetual motion.

But the Fermentation of Wine and of Blood, differs in this; that in Wine there is no waſting of the old parts, and a coming again of new; but the Liquor being ſhut up in the Veſſel, remains ſtill the ſame: but 'tis otherwiſe in Blood, in which ſome parts are continually deſtroyed, and in their place others are always generated anew. In Wine, the times of crudity, maturation, and defection, are diſtinct, and are ſucceſſively performed in the whole: In Blood, that threefold ſtate is celebrated at the ſame time and by parts: Fermentation being once begun in Wine, is continued even to the end; but in Blood, becauſe it is waſhed ſtill with crude Juices, it ought ſtill to be renewed; by which means, the Nutritious Particles, not of kin, are aſſimilated to the reſt of the Latex; wherefore, for this work, beſides the Fermentation once begun in the Blood, there is need of ſome Ferments, which may continue the ſame, otherwiſe about to leave off.

That Ferments are required for the making of Blood, this is an Argument; that when they are wanting by Nature, they are with good ſucceſs ſupplied by the work of Art: for fixed Salts, Alkali Salt, Extracts, Digeſtives, Openers, and eſpecially Chalybeat Remedies, help for this reaſon, that, as it were by a certain Ferment, they reſtore anew, the weak, or almoſt extinct Ebullition, or boyling of the Blood.

As to what reſpects the Natural Ferments, very many may certainly be formed, and in divers parts, or hid in the Bowels; for any Humor in which the Particles of Salt, Sulphur or Spirit, being much exalted, are contained, puts on the Nature of a Ferment: after this manner, the flowring or dregs of Beer or new Wine, being kneaded with Meal, and the Maſs kept to ſowrneſs, come under this rank, by which new Beer, and the like Liquors, as alſo the Maſs of Bread, are more excellently fermented. In like manner in the Ventricle, a ſowriſh Humor participating of exalted Salt, there helps Concoction: and in the Spleen, the feculencies of the Blood from Salt and Earth being exalted, go into a Ferment-

How

How much vigor comes to the Blood from the Womb and Genital Parts, appears from hence, becauſe by the privation, or evil diſpoſition of them, follow, in Maids the Green-ſickneſs, in Men, Barrenneſs or loſs of Virility, want of Beard, and a ſhrill Voice. But the chief Ferment, that ſerves for ſanguification, is eſtabliſhed in the Heart; for this is the chief fire-place, in which the cruder Particles of the Chyme, are as it were inkindled, and acquire a volatileneſs: which thing may be confirmed by many reaſons, but eſpecially by its effects, which we ſuffer in the Precordia, as often as the Blood ferments more or leſs than it ought to do: for when it is too much inkindled in the Heart, it is agitated impetuouſly, as it were by fires put under it; the ſigns of whoſe immoderate Ebullition are, a deep pulſe and vehement, then almoſt an intolerable heat in the Precordia, with a vehement thirſt; on the other ſide, when the Fermentation of the Blood is leſſened in the Heart, we are affected with an anhelous, and difficult reſpiration upon any motion; as may be perceived in the Dropſie, Cachexia, and Yellow Jaundice: the reaſon of which is, not becauſe the Lungs are ſtuffed, or filled full of a tough or clammy matter; but becauſe the Blood doth not rightly ferment, in that Repoſitory of Fermentation; wherefore, being fallen into its Boſom, it is not preſently Rarified; nor doth it ſoon leap forth into the Lungs, but being apt to ſtagnate, and remain there, cauſes an oppreſſion of the Heart it ſelf; for the helping of which, frequent breathing is made, that the Blood being let forth into the Lungs, ſuccour might be brought to it: but if by motion or exerciſe, the Blood be more provoked into its Ventricle, than can be derived by reſpiration, or the pulſe, into the Pneumonic Veſſels, there is danger of choaking. The like happens in thoſe that are dying: when the pulſe is very ſmall, and the Blood being heaped up in the Heart for want of Fermentation, begins to ſtagnate and to clodder, we then breath deeply, with a noiſe and elevation of the breaſt; to wit, the Blood with the ultimate endeavour of Nature, and the whole force of the Lungs, as long as it is able to be done, is emptied forth into the Lungs, leſt reſiding in the Heart, it ſhould wholly choak it.

Therefore, Motion and Heat, in the Blood, depend chiefly on two things, *viz.* partly on its own proper diſpoſition and conſtitution, by which, it being forged very greatly with active Principles of Spirits, Salt, and Sulphur, of its own accord ſwells up, or grows turgid in the Veſſels, even as Wine in the Ton: and partly on the Ferment implanted in the Heart, which very much rarifies the Liquor paſſing through its Boſom, and makes it to leap forth with a frothy heat: that the Blood, which is quietly inſtilled to the Heart through the Veins, running gently like a River, from thence leaping forth through the Arteries, (like a Torrent) with noiſe and rage, might be carried forward, to all the parts of the whole Body. By what means this is done, though it is not eaſie to explicate Mechanically, yet the manner, and ſome not improbable reaſons of this thing, are delivered by moſt Learned men, *Ent*, *Cartes*, and others. They ſuppoſe indeed, as it were a fire to be ſet in the Chimny of the Heart, which preſently inkindles the Blood infuſed through the Veins, (even as a flame put to Wine burns it) which being ſo inkindled, by its deflagration (like lightning) paſſes moſt ſwiftly through the Arteries: ſo that heat, a moſt rapid motion, and *Effluvia* ſent by Perſpiration, are wont to proceed from the accenſion of the Blood in the Heart only. *Hogelandus* affirms, that there is a Ferment hid in the Boſom of the Heart, that compels the Liquor of the Blood to boil up, and to grow hot, with heat, and a plentiful emiſſion of Soot, juſt like Spirit of Nitre, when it is poured on the Butter of Antimony: ſo that the Blood, flowing in gently through the Veins, being forthwith Rarified into ſpume and vapour by the ferment of the Heart, runs very impetuouſly through the paſſages of the Arteries. 'Tis almoſt the ſame thing, whether it be ſaid to be done, either by this, or by that way: for the alteration which the Blood receives in the Heart, may be equally deduced from a flame, or a Nitrous Sulphureous ferment, there ſuppoſed to be placed. Becauſe, whilſt the Blood ſlides into the Ventricles of the Heart, preſently the frame of the Liquor is looſned, and the active Particles, eſpecially the Spirituous and Sulphureous, the bond of the mixture being broke, do leap forth from the reſt, and ſtrive to expand themſelves on every ſide; but being kept in by the Veſſels, and being forced together with the remaining Liquor, through the open paſſages of the Arteries, they ruſh with violence, and ſwelling up by the way they can find, and by that means, diffuſe *Effluvia* of heat, through the whole body: there is little difference, whether the expanſion of the Particles of the Blood, and exertion into the liberty of motion, be ſaid to be done by Accenſion, or by Fermentation, foraſmuch as by either way, the frame of the Blood may be ſo unlocked, that from thence the Particles of Spirit, Salt, and eſpecially of Sulphur, being incited into motion, (as it were by an inkindled fire) may impart heat to the whole Body.

But this Rarefaction, or Accenſion of the Blood in the Heart, very much depends upon the diſpoſition and conſtitution of the Blood it ſelf: for if its Liquor be rightly cocted, being made volatile, and (like rich Wine) brought to maturity, it then Ferments there after its due manner, whereby the ſoluted Particles of the Spirits and Sulphur, diffuſe an equal, and moderate heat to all parts. But if the blood, by reaſon of an ill manner of feeding, and want of Concoction, be crude and watry, then it is leſs inkindled in the Heart; and from thence follow a

frigid

frigid intemperance of the whole, difficult breathing and wheesing, with a weak pulse, and languishing; as in Cachectical people, those distempered with the Green-sickness, and such as are about to die, may be perceived: but if the Blood becomes too luxuriant, and apt to grow turgid, by reason of plenty of Sulphur being carried forth, or of its *Effluvia* being restrained, or of eating hot things; either its Accension or Fermentation in the Heart, is very much increased, so that from thence a Feaverish heat, and greater effervescencies than usual, are stirred up in the whole. This various Fermentation of the Blood in the Heart, according to the various temper of the same, may be illustrated by the example of Wine: fresh Must, that is yet crude, though it be boiled, or put on the fire, will not burn; but this being purified and brought to maturity, is easily inkindled, but sends forth a small flame, and quickly out. The same at first growing hot, or otherwise warmed, if inkindled, is greatly inflamed, and for the most part is consumed by its burning.

Whilst the Blood, after this manner being rarified, or inkindled in the Heart, and from thence growing hot, through the passages of the Vessels, is resolved into minute parts, some little bodies depart from its loosned frame, which refuse at last to be united, and fitted with the rest of the Liquor: but these are of a twofold Nature; either thin, which like smoke from the burning fire, or *Effluvia* from a Fermenting Liquor, do evaporate from the Liquor of the Blood, by a constant Diaphoresis, through the breathing holes of the Body; or more thick, which like ashes left after burning, or the settling dregs after Fermentation, ought to be soon strained from the mass of Blood, and to be carried forth of dores: for otherwise, by their confusion, they produce notable perturbations in the Blood. Whereby the Blood growing more hot, is dissolved in the Heart, therefore these Recrements, both Fuliginous and Earthy, are more plentifully heaped together; and when by reason of too great congestion, they cannot be presently subdued and secluded from the mass of Blood, they bring forth a swelling up of the Blood and Feaverish Heats.

Concerning the Motion, Heat, and Natural Fermentation of the Blood, in the equal tenor of which, the means of our Health consists, what hath hitherto been spoken, shall suffice. We will treat a little more largely of the preternatural, or too great effervescency, on which the Types, and Paroxysms of Feavers depend: I call that too much, or Preternatural Fermentation, when the Blood, (like a Pot boiling over the fire) grows hot above measure, and being rarified with a swelling spume, distends the Vessels, excites a more quick pulse, and like a sulphureous Liquor, having taken fire, diffuses a burning heat on every side.

This kind of motion or Fermentation of the Blood, will be best of all illustrated by an example of Wines growing hot. For Wines, besides the gentle and equal Fermentation, by which they are at first purified, at some times do so remarkably grow hot, and boil up, that they fly out of the mouth of the Vessel, and if they are closely stopped up, cause it to burst in pieces. After this manner, as if struck with fury, unless they are immediately drawn away from the Tartar; or their Lees into another Vessel, they will not cease from growing hot, until the Spirit being very much loosned, and the Sulphur or Salt too much exalted, they are either made unsavory, or degenerate into a sowrness.

Such an Effervescency is wont to be stirred up for two causes chiefly: First, When any extraneous thing, and not miscible, is poured into the Ton, (so some drops of Tallow, or Fat, being dropped into the Cask, will produce this motion) or secondly, when Wines being enriched with too rich a Lee or Tartar (by reason of the sulphureous parts being above measure exalted) conceive heats of their own accord, and exceedingly boil up. For in whatsoever substance Sulphur abounds, and its Particles being loosned from the mixture, consociate together, and are bound close in one, there such immoderate heats are procured.

After a like (tho' not wholly the same) manner, whereby Wines grow hot, the boiling up of the Blood is induced; to wit, either what is forein, and not akin to the Blood, is mixed with it, that when it is not assimilated, is wont to cause a Perturbation, and growing hot, until that Heterogeneous thing, is either subdued or cast forth of dores; and the Particles of the Blood being confused and troubled, are at last shaken forth, and that they get again their former place and position in the mixture. Or, Secondly, the Blood grows hot above measure, because some Principle, or its constitutive Element, (*viz.* Spirit or Sulphur) is carried forth beyond its Natural temper, and becomes enraged; whereby indeed the Particles of this or that, being not agreeable to the rest, are loosned from the mixture; being loosned, they become more violent than they ought, shake much the Liquor of the Blood, and bring forth a heat, which is not allayed, till the Blood being as it were inflamed, burns forth with the long fire of a Feaver. By either way, whether the Blood grows hot in the Vessels, by reason of the pouring in of a thing not miscible, or by reason of the rage of the Spirit, or Sulphur being carried forth, because from thence its frame is more loosned, therefore it is more inkindled in the Heart; and the active Particles first loosned from the Ferment there implanted, do grow exceeding hot, leap forth from the mixture, and disperse on every side by their motion, a strong heat, and as it were fiery: but yet with this difference, that the Effervescency, which depends upon the mingling

mingling of ſome extraneous thing with the Blood, is for the moſt part ſhort, or renewed, which, when what was Heterogeneous is ſeparated or ſubdued, is quieted of its own accord, and the ſhaken parts of the Blood, and put out of order, eaſily return to their Natural ſite and diſpotion. But the Ebullition which ariſes from the inordination of the Spirit or Sulphur being enraged, is continual; to wit, here the whole maſs of the Blood is ſo looſned, and diſſolved from the ſtrict bond of the mixture, that as an Oily Liquor having taken fire, it ceaſes not to grow hot, or to be inflamed, till the Particles of Spirit, or Sulphur, or the combuſtible matter, be for the moſt part burnt out.

There remains yet a third manner of Preternatural Fervency, whereby the Blood is ſubject to alteration, which happens not to Wine, but moſt often to Milk; *viz.* when at any time, from a Morbific cauſe, a coagulation of its Liquor is induced, ſo that its ſubſtance is poured forth, and goes into parts, and there is a ſeparation made of the thick and earthy from the thin; by which means the Blood is not fitly circulated in the Veſſels, but that its congealed portions, being apt to be fixed in the extream parts, or to ſtand ſtill in the Heart, do interrupt the equal motion, or grievouſly hinder it: For the ſake of the reſtoring of which Effervency, greater are wont to be ſtirred up in the Blood, to wit, ſuch as happen ordinarily in a Pluriſie, the Plague, Small Pox, or the Venereal Diſeaſe.

CHAP. III.

Of Intermitting Feavers or Agues.

BY the Premiſes which we have ſpoken of already, concerning the Anatomy, Motion, and Heats of the Blood, there now lies open an eaſie paſſage to the handling of Feavers. The Notions which are commonly ſet forth, concerning a Feaver, out of the force and Etymology of the word, I here purpoſely omit: It may be deſcribed after this manner, that it is, An inordinate motion of the Blood, and a too great Heat of it, with burning and thirſt, and other Symptoms beſides, whereby the Natural œconomy or Government, is variouſly diſturbed. As we have remarked already, concerning the growing hot of the Blood, ſo now we do of a Feaver, that indeed, its acceſſion is either ſhort, and by fits, which is therefore termed Intermitting; or elſe great, and long protracted, which is called a continual Feaver. We will firſt ſpeak of the Intermitting Feaver.

Tho' an Intermitting Feaver, in our Popular Idiom, is known by a proper Name, and is diſtinguiſhed contrary to a Feaver commonly taken, yet becauſe it hath too great Effervency of the Blood joyned to it, it is to be called a Feaver. It is peculiar to this, from a continual Feaver, that it hath certain remiſſions, or times of intermiſſion; that every fit begins with cold or ſhaking, for the moſt part, and ends in ſweat; that the acceſſions or coming of the fits, return at ſet Periods, and certain intervals of times, that a Clock is not more exact. Wherefore, we will firſt diſcourſe concerning this Feaver in general, what ſort of heat of the Blood it is which continues its fit, and from whence it is raiſed up. Secondly, Wherefore the fit appears equally with cold and ſhaking, as with ſweat following. Thirdly, What may be the cauſe of the Intermiſſion, as alſo of its certain ſet Periods. Fourthly and Laſtly, Are added ſome irregularities of Intermitting Feavers, as when now cold, now heat or ſweat is wanting; or when the Periods are wandring and and uncertain, when the Remiſſion or ſpace of Intermiſſion, is not equal, but now comes ſooner, now later, and ſometimes redoubled: and I will endeavor to ſhew the reaſons of theſe, and of other Phenomena or appearances, which variouſly happen in this Diſtemper. Theſe being laid open, we will go on to unfold in the next Chapter, the diviſion of an Intermitting Feaver, and the kinds of it.

As to the firſt: The Effervency of the Blood in an Intermitting Feaver, (or Ague) for the time of the fit, is as violent and ſtrong as in a continual Feaver: wherefore, it is concluded, that the parts of the Blood, among themſelves, or ſome heterogeneous thing being mixed with it, do ſtrive together, and ferment above meaſure. But there is required, that they may ferment, or too greatly boil up among themſelves, that ſome Principle, as chiefly Spirit or Sulphur, being too much exalted and enraged, do appear above the reſt; which, when it cannot be yoaked with them, brings in a continual ſtrife and heat: but from this cauſe, a continual Feaver draws its riſe, becauſe ſuch an Ebullition of the Blood, being once begun, is not ſuddenly allayed, and when it is appeaſed, it does not afterwards preſently return. Wherefore for an Intermitting Feaver, 'tis to be ſuppoſed, that ſome heterogeneous thing is mingled with the Blood, whoſe Particles, when they are not aſſimilated, make ſo long an Ebullition of the ſame, till either being kneaded, they are rendred miſcible, or being ſubtiliſed, are ſhut forth of dores. Wherefore, ſuch a matter being brought under, or

ſhut

ſhut forth of dores, the fit ceaſes, and when this matter ſprings again, it ſtirs up a new Ebullition, and ſo a new fit is brought on.

Concerning this Matter, which being mixed with the Blood, induces the periodical Heats, and the other Symptoms of an Intermitting Feaver, 'tis very ambiguouſly, and diverſly diſputed among Phyſicians, where it is generated, in what ſeat or place it lodges, and by what means it ſo exactly obſerves the times of its Motion, and Ebullition. But it would be a work of too much labour and tedioufneſs, to recount here all the Arguments, of the Ancients, and Moderns, to reduce them into order, and to weigh their reaſons; Wherefore, doubting, I propoſe what has come into my mind, when I thought deeply of the matter, and ſubmit to the Judgment of others.

Of neceſſity there is ſomething, which brings in the Heat of the Bloud exactly periodical, that is generated in our Body at the ſeveral periods, or acceſſions of the Feaver, always in a ſet meaſure, and equal proportion, and is communicated to the maſs of Bloud; with which when the Bloud is filled to a plenitude, it forthwith grows turgid, and conceives an heat: But this is ſuppoſed to be either an Excrementitious humor, ſliding down into ſome Mines, which by de-degrees, and at a ſet time, being brought to an increaſe, and moved, Ferments with the Bloud: or it is the nutritious Juice, ſupplied from the matter of Food, and delated in weight and meaſure, which, when it is not aſſimilated, by reaſon of a defect in ſanguification, being heaped up to a fulneſs, for its own expulſion, induces a turgency in the Bloud. The reaſon of Intermitting Feavers, is commonly explicated by the former way, and the cauſes of the Intermiſſion, and ſet times of approach, are fetcht from the nature of the Humor, and the ſeat, or place where it is cheriſhed. The Neſt, or Mine of this Diſeaſe, almoſt by an unanimous conſent, is fixed on the firſt ſhop of the Body, and from hence the reaſon of the Intermiſſion is fetched, and the continual difference of an Intermitting Feaver: but they affirm the matter to be Choler, Phlegm, and Melancholy; and as theſe humors are ſaid to putrifie ſlower, or ſooner, ſo the Feaveriſh courſes, are ſaid to be abſolved, in the ſpace of one or more days. But this Opinion, after the Circulation of the Bloud hath been made plainly known to all, is deſervedly rejected. For when the Bloud never ſtagnates in the Veſſels, but waſhes every place with a perpetual motion, and continually carries away their filth, it is impoſſible that the Mine of this Diſeaſe ſhould ſubſiſt in the Meſaraick, where it is commonly aſſerted to be: as to what belongs to the cavities or dens, for the heaping up of the humors in the Viſcera, it neither appears, by what means ſuch ſhould be formed without a Tumor or Impoſthume; nor by what inſtinct, ſuch humors, ſhut up in their Neſt, do increaſe, are conſumed, and laſtly ſpring forth again, at ſo exact intervals of times. Beſides, what is affirmed concerning Bile, Phlegm, and Melancholy, and of their periodical motions, we hold wholly ſuſpected; becauſe theſe ſort of humors, are not afforded ſincere, ſuch as are deſcribed in the Schools: but the Bloud, having gotten a various diſpoſition, now being hotter, now colder, its nature imitates the qualities of ſuch humors; or in its Circulating, it lays aſide its Recrements, which being depoſited in little Cheſts or Veſſels, are falſely believed to be Morbific, and Preternatural humors. Wherefore, as the nutritious Juice, is the only humor wherewith the maſs of Bloud is daily refreſhed, and its ſupplements are made ſtill in meaſure, and proportion, without doubt, the periodical heats of the Bloud, are to be drawn from the acceſſion and commixtion of this.

I have already remarked concerning the Particles of the Bloud, a triple ſtate of crudity, maturation, and defection: to wit, the nouriſhing Juice, ſupplied from the daily Food, comes crude, is mixed with the Bloud, and being for ſome time Circulated, is aſſimilated to it, and is ripened into a perfect humor: afterwards growing ſtale, it goes into parts and is laid aſide. Whilſt after this equal manner, the Bloud is continually reſtored, and its loſſes repaired, it very quietly Ferments, without any trouble, or immoderate heat, and is Circulated within the Veſſels; but if the ſupplement of the nouriſhing Juice, is not (as before) ripened, nor goes into Bloud, by a perfect digeſtion, its Particles being confuſed with the Bloud, remain as it were ſome Heterogeneous thing, and not exactly akin, in the maſs of Bloud; with which, when it is filled to a plentitude, the Bloud forthwith grows troubled, and conceives a Feaveriſh heat, whereby the freſh ſupply of this depraved Juice, is either overcome, or caſt forth of dores. I ſay, therefore, from the firſt inſtant, in which the nouriſhing Juice is not aſſimilated with the Bloud, its Particles, though mixed with it, are as yet Circulated with it, without any great tumult or perturbation, and ſo afterwards, till the maſs of the Bloud is filled with them to a turgency: but then it quickly boils up, and conceives a heat: almoſt after the ſame manner, as new Beer put into Bottles, which, if they are cloſely ſtopped, that nothing may evaporate, is at firſt contained in thoſe Veſſels, without heat, or force; afterwards, when the *Efflivia* being ſtill reſtrained, the maſs of the Liquor ſwells up, notably Ferments, and by reaſon of the force of Fermentation, oftentimes makes the Bottles fly in pieces: alſo this happens at a ſet time, and in the ſpace of ſo many hours, as in an Intermitting Feaver, the Liquor ariſes to its height of turgeſcency.

There yet remains a difficulty, for what cauſe the Nutritious Juice, being confuſed with the Bloud, is not aſſimilated, but degenerates into an Heterogeneous, and Fermentative Matter: I ſuppoſe this to be done, for the moſt part, not by the default of the Aliments, nor yet of the Bowels, but by the vice of the Bloud it ſelf. For the Bloud, even as Wine, ſometimes paſſes from its native and genuine diſpoſition, into an acid, ſowr, or auſtere diſpoſition; and becauſe the Bloud makes Bloud, it comes to paſs, that when it is departed from its due temper, it eaſily perverts the proviſion of the Nutritious Juice, by which it ſhould be repaired. What that diſpoſition of the Bloud is, and by what means contracted, ſhall be told hereafter, when we ſpeak of the kinds of Intermitting Feavers, and of their evident, and Procatarctick Cauſes. The Heat, or Effervescency therefore of the Bloud, which conſtitutes the fit of an Intermitting Feaver, depends only upon the aſſimilation of the nouriſhing Juice being hindered; the Particles of this being commixed with the Bloud, are not (as before) ripened, nor are made into perfect Bloud; but by the mixture of theſe, the maſs of Bloud (as it were new Drink) is imbued with little bodies greatly Fermentative; when the which are more thickly heaped together, and the Bloud is filled with them to a ſwelling up, it preſently grows hot, and a mighty agitation, and ſtriſe of the Particles is made, by which, they break, and ſubtiliſe one another, till at length the Vital Spirit getting the dominion, and the reſt being brought under, what is extraneous is thruſt forth of dores, from the company of which, the Bloud being freed, the remiſſion, and intermiſſion of the aguiſh fit follows; but afterwards from a new ſupply of this Juice, a new fit is brought on.

Secondly, As to the ſhaking, or cold preceding the heat, in this Diſtemper, I ſay, when the Particles of the nouriſhing Juice, do proceed from a ſtate of crudity, towards maturity, but do not attain it, they contract a notable ſowriſhneſs, with which they greatly prick, and haule the nervous parts, and cauſe the ſenſe of cold: even as new Beer, which being ſtopped cloſe in Bottles, paſſes from a ſweet into an acid and nitrous taſte, that for the cuttingneſs and cold, can ſcarce be ſwallowed. When therefore, the Particles of this ſort of crude Juice, being indued with a Nitrous ſowrneſs, do fill the maſs of the Bloud to a fulneſs, or to a ſwelling up, and when they being more thickly heaped together, begin to enter into a Flux, they firſt of all ſtrike down the Vital Spirits, with their ſharpneſs, and ſomewhat overthrow their heat; wherefore the Bloud becomes colder, and is more ſlowly circulated: yea, and by reaſon of the defect of heat, the ſenſe of cold is perceived in the whole body, and a pulſe very rare exiſts. Moreover, When the nervous and ſolid parts, are watered with this ſort of acetous Juice, for their laſt nouriſhment, by the Flux of this, which happens together with the turgeſcency of the Bloud, theſe ſenſible parts are pulled, and irritated into Tremblings, and Convulſions. And this, without doubt, is the true and genuine Cauſe of the cold and ſhaking, which are excited in a fit of the Intermitting Feaver; to wit, the Flux, and ſwelling up of the nouriſhing Juice, degenerated into a Nitrous Matter, with which the Spirits and heat being ſuffuſed, are blunted, and the Nervous Bodies, being provoked, are moved into Tremblings. But afterwards, when theſe Nitrous Particles being thruſt forth, from ſome part, into the Superficies of the body, the Bloud is ſomewhat freed from their weight and oppreſſion, the Vital Spirits recollect themſelves, and begin to ſhine forth; but from thence a moſt intenſe heat ſucceeds; becauſe, both the maſs of Bloud, by reaſon of the growing hot with the Feaveriſh Matter, being looſened, and alſo it mixture being laxed, the Sulphureous Particles are more plentifully inkindled in the Heart; and becauſe (the Pores of the Skin, being poſſeſſed by the ſame Matter, thruſt forth towards the circumference of the body) the vaporous *Effluvia* are reſtrained within, which do more ſhake, and make hot the the Bloud; that heat perſiſts ſtill in the Bloud, until that Fermentative Matter being wholly burnt out, and together with the aduſt recrements, remaining after the burning, being fully brought under, and ſubtiliſed, and involved with the *Serum*, inſenſibly evaporates by ſweat, or tranſpiration.

Thirdly, Theſe things being premiſed, it will not be hard to ſhew the Reaſons and Cauſes of the Intermiſſion, as alſo of the ſet Periods, *viz.* the Intermiſſion follows, becauſe all the Morbific Matter is diſperſed in one fit, and ſo till new be ſubſtituted, there is a neceſſity that a remiſſion follow. But new Matter begins to be begot, of which the laſt fit failed; to wit, the maſs of Bloud being now emptied, receives the nouriſhing Juice, and perverts it (as before) by reaſon of its defect of due making of Bloud, and of Concoction, into a Fermentative Matter; but its little plenty ſtirs up little or no trouble, or Fermentation; but when the Bloud is filled to a ſwelling up, it preſently Ferments, and is in Flux, even as when new Beer, or new Wine, ſhut up a long while in a Veſſel, at length, at a certain time, boils up, and leaps forth at the mouth of the Veſſel.

But that the Fits, or Acceſſions, do for the moſt part come again, at ſet intervals of times, and that ſo certainly, that a Clock is not more exact; the reaſon is, becauſe the nouriſhable Juice, is

for

for the moſt part ſupplied from the Viſcera, to the Blood flowing in the Veſſels, in an equal meaſure and manner; for though we do not daily take exactly ſo much meat and drink in weight and dimenſion, yet, becauſe we for the moſt part eat at ſet hours, for the ſatisfying the Appetite, from the things eaten, and the maſs of the Chyme heaped up in the Bowels, an equal portion of the nutritious Juice is conveyed to the Blood through the Milky Veſſels; wherefore, if at ſuch hours, ſo much of the nutritious humor is poured into the Blood, which encreaſing to a fulneſs, and ſwelling up, it brings on the Fit that day: certainly, this being finiſhed, in the ſpace of the ſame time, ſufficient matter is laid up, for the following fit: But if Errors in feeding be committed, and that the ſick indulging their Appetite, eat more plentifully or inordinately, the approach of the fit anticipates the wonted hour, by reaſon of the Bloods being filled ſooner with the Feaveriſh Matter; if that the ſick are abſtemious, and more ſparingly take their food, the intermiſſion is drawn out longer.

If it be yet asked, wherefore the periods of intermitting Feavers be not of one kind, and of the ſame diſtance, but that ſome repeat, and come again daily, others on the third and fourth day? The cauſe is the diverſe conſtitution of the Blood, to wit, whereby it is perverted from its due temper, now into a ſowriſh, now into an acid or ſharp,, or into an auſtere or harſh diſpoſition. By reaſon of the diverſe evil conſhitution of this, the alible Juice, being freſh carried, departs more or leſs from maturation, and is perverted into matter, apt ſooner or later to ferment. When the Blood has acquired a ſowr, hot, and bilous diſpoſition, I ſuppoſe that ſome part of the nouriſhing Juice is ripened into perfect humor, and is aſſimilated with the Blood, and ſo goes into food, to be carried to the ſolid parts, and is affixed to them; but the other part of it, from the Blood being too much cocted, and depraved, is changed into a feaveriſh matter, and ſuppoſing that half of the nutritious Juice is after this manner perverted, in double the time, in which it is ſaid to have a full concoction in our Body (that is, after eight and forty hours) this kind of fermentative matter riſes to a plenitude and turgeſcency, and then induces the fit of a Tertian Feaver. If that, by reaſon of the auſtere, and pontic nature of the degenerated Blood (in which a fixed Salt, with an earthy *Faces* is exalted too much) and therefore apt to ferment more ſlowly, only a third part of the nutricious Juice is corrupted, then in three times the ſpace of the aforeſaid time, the fit is induced; that is, after ſeventy two hours, in which, the period of a Quartan is wont to be concluded. But, if by reaſon of a greater infection of the Blood, almoſt the whole ſupplement of the nutricious Juice is perverted into a Feaveriſh matter; then in the ſpace of that time, in which the plenary coction ought to be abſolved in the Veſſels and habit of the body (that is, after twenty four honrs) this matter ariſes up to the motion of turgeſcency, and brings on the quotidian fit. And hence it comes to paſs, that in a Quartan Feaver, ſtrength and courage do not preſently fail, whilſt in a Tertian, the ſick are wont to become more weak; but in a Quotidian Feaver, they are ſooner brought into languiſhing, and greateſt weakneſs: to wit, in each, as more or leſs of the nutricious Juice goes into the food of the Diſeaſe, ſo much alſo is drawn away from the ſtrength and firmneſs of the Body. But more fully of theſe, when we treat of the ſeveral kinds of Intermitting Feavers, and the Cauſes of them.

Againſt the equal Circuits of theſe Feavers, it is argued, that for the moſt part, the fits do anticipate the ſet time of the day, by the ſpace of ſome hours, and ſometimes alſo come after it. But in truth this Objection is taken away, if the times of Intermiſſion be computed, not by days, but by hours; for ſo the intervals which but now ſeemed to be now ſooner, now longer protracted, will appear for the moſt part equal, by this Rule; foraſmuch as in reſpect of the day, it is ſaid a Tertian Feaver, ſometimes prevents the wonted time of its acceſſion, two, three, or more hours, or comes after it; in the mean time, every Circuit exactly repeats or comes again, every time after ſo many hours. Wherefore the chief differences of Intermitting Feavers conſiſts in this only, that the time of the acceſſion in one Feaver, comes more ſwiftly, and in another more ſlowly, *viz.* now at twenty four hours diſtance, now at thirty four, now at ſeventy, or the like.

From what hath been ſaid (unleſs I am deceived) it clearly appears, what the Efferveſcency of the Blood is, which conſtitutes the fit of an Intermitting Feaver, from whence the fore-runners of cold and ſhaking, and laſtly, what may be the reaſon of the Intermiſſion, and of the ſet periods. But that theſe, and many other Appearances of this Diſtemper, depend upon the evil diſpoſition of the Blood, and becauſe of the depravation of the nutricious Juice, and not from humor, lurking in ſome Mine, will yet more manifeſtly appear from the collation of the Signs and Symptoms, which are to be met with, worthy of note, in this Diſtemper: then ſecondly, from the Procatartic, or more remote cauſes being truly weighed, which are wont to induce this Diſtemper: And thirdly, and laſtly, from the ways of the Criſis, and Cures, by which this Diſeaſe either ceaſes of its own accord, or is driven away, by the help of Medecines.

Firſt, Among the Signs, the Pulſe and Urine deſerve the chief conſideration: The Pulſe, the cold fit coming on, is very rare and low; which clearly argues, the Heat, and Vital Spirits

in the Blood, to be as it were overwhelmed by ſome crude matter, not eaſily combuſtible; juſt as a fire enkindled on the Hearth, and then covered with green wood, glows very ſlowly, and flames forth very little, which afterwards, the crude humor being blown away, breaks forth into an open and very ſtrong flame; ſo alſo, the Blood, the crude matter, which is in Flux, being ſomething overcome or diſperſed, is very much enkindled; and what remains in the Blood is burnt up, when fermenting with the Particles of it, and induces a moſt violent heat, with thirſt; wherefore the Blood growing impetuouſly hot, is urged with a vehement, and moſt ſwift Pulſe; otherwiſe it being too much heaped together in the Heart, might cauſe the danger of choaking.

As to the Urine; that is imbued (eſpecially, in a Tertian Feaver) with a deep colour, and as it were enflamed, alſo when the contents are wanting; which ſeems to denote a ſcorching of the Blood, and too aduſt temper: moreover, in this Diſtemper, different from others, the Urine, for the moſt part is ill, when the Patient is pretty well, and on the contrary; foraſmuch as all the time of the Intermiſſion, it is at a great diſtance from its natural ſtate, it becomes filled with a red colour, and thick, being expoſed to the cold, and lays down a plentiful ſediment, like to Bole-Armoniack; which is of neceſſity to be ſo done, becauſe in the whole interval of the remiſſion, the Feaveriſh matter is circulated with the Blood, and there riſes to maturity, with a ſecret increaſe. But in the middle of the fit, when the heat and burning are at the greateſt, the Urine is laudable, and comes more near to the natural, *viz.* the fermentative matter, being ſent to the circumference of the Body.

The Symptoms preceding the fit, confirm the ſame thing; for many hours before the fit begins, a perturbation of the humors, and blood, is perceived; an Head-ach, Vertigo, ſparkling of the Eyes, unquiet Sleep, *&c.* which plainly ſhew the Blood firſt infected with the fermenting matter, and the aſſault of the fit to be only ſo long deferred, until the maſs of the Blood is filled to a ſwelling up, with the ſame kind of matter: the fore-runners of the approach of the fit, are, now a paleneſs at the ends of the Fingers, or Toes, or in the Nails, ſometimes a convulſion or numneſs; now a coldneſs, and pain in the Loins and Thighs, and ſometimes a ſhivering and trembling invade the Body, which clearly ſhew, the Blood in the Arteries and Veins, and alſo the thin Liquor in the Nervous parts, firſt to conceive the motion of Fermentation, and this Effervency not to be excited from any other Fire-place, or Mine. If it be objected, that the ſick are moſt often infeſted with Vomiting, about the time of the fit; from whence it may ſeem to be concluded, that the chiefeſt hurtful matter is eſtabliſhed in the Ventricle, and in the firſt paſſages, eſpecially when this Diſtemper is chiefly cured, by the timely taking of a Vomit; I confeſs, very great Vomitings are ſometimes ſtirred up in the fit of an Intermitting Feaver; but this more often happens, becauſe in the Feaveriſh ſhivering, the membranes of the whole body are pulled; wherefore the Ventricle alſo. as it is a very Nervous part, is diſtempered with a Convulſion, and having from thence contracted a Spaſm, caſts forth upwards whatſoever lurks in its boſom. Beſides, if that the choler-bearing Veſſels ſwell up with Bile or Choler, by the ſame Convulſion alſo of the Viſcera, the Bile is preſſed forth into the Duodenum by the galliſh paſſage, and is emptied into the Ventricle, and there by its fierceneſs, provokes yet to a more cruel vomiting, wherefore for the moſt part, the vomiting which is excited for this reaſon, follows the ſhaking only. But that the Choler was not in the Stomach before the fit troubled it, but only preſſed forth from the Choleduct paſſage, by the Spaſm and convulſive motions of the Viſcera, and poured forth into the Ventricle, appears from hence, becauſe if a Vomit be given in the midſt of the interval, between the two fits, little or nothing of bilous matter will be drawn forth; beſides this bitter humor is of that fierceneſs, that it cannot be long contained in the Ventricle, but preſently it will procure the pain of the Heart, and Vomiting. Beſides this ſort of Vomiting, excited in the ſhaking fit, ſometimes a Vomiting is provoked in the midſt of the burning fit, or in the ſweat, the cauſe of which is the redundancy of the biliſh humor in the Blood; of which if there be greater plenty, than what diluted with *Serum* may be ſent forth by Sweat, a great part of it, whilſt the Blood is circulated about the Creviſes of the Liver, is laid aſide in the Choleduct Veſſels; which, when being filled to a diſtention, exonerate themſelves, and ſend away the Choler to the Inteſtines and Ventricle, and there a Convulſion being preſently ſtirred up, ſometimes Vomiting is provoked, and ſometimes the belly becomes looſe, and the Stools liquid. In this Year 1657. I obſerved very many affected after this manner, for when after an hot and dry Summer, about the middle of Autumn, an Intermitting Feaver generally raged, the ſick were wont ſuddenly to grow very ill, in the middle of their hot fit, and ſometimes alſo in their Sweating, and the Sweat being ſtruck in, to be taken with Swooning; but ſhortly after, when a Choleric Vomiting followed, they were eaſed.

Not only the ſigns and ſymptoms, but the Procatartic or more remote Cauſes of this Diſeaſe, clearly indicate, that it takes its riſe from the temper of the Blood being changed; becauſe Intermitting Feavers are moſt frequent in the ſeaſon, and places, in which the Blood receives the greateſt alteration from the Air, *viz.* either in the Spring, when the Vernal heat ſhutting out the Winters Cold, cauſes the Blood, before benummed, and apt to be more ſlowly moved, to begin

to

to flouriſh, and luxuriate in the Veſſels, and from thence, to get a bilous and hot temper: or in the Autumn, when the Blood being torrified, or roſted by the Summers heat, and therefore its Spirits very much depreſſed, and Salt and Sulphur exalted, acquires now a ſharp and Choleric, now a binding and auſtere diſpoſition; wherefore, at this ſeaſon, Feavers, now Tertian, now Quartan, are frequent; beſides, in ſome places, there is that conſtitution of the Heaven, that on all men whatſoever, there comes either a Tertian or (more frequently) a Quartan Feaver; although in the firſt Offices, where the Mine of the Diſeaſe is commonly believed to be lodged, there be no congeſtion of humors, by reaſon of an ill manner of living, or ſickly diſpoſition. Yea, they moſt eaſily fall into this Diſeaſe, who have their Inwards firm and ſtrong, and who abound with a lively heat: on the contrary, thoſe who by reaſon of a weak concoction, heap up Crudities in the firſt paſſages continually, that they are prone to the Dropſie, or Cachexia, remain free, for the moſt part, from this Diſtemper, to wit, the Blood being made more watery, (like Wine degenerated into a taſteleſs ſubſtance) is altogether unapt to be fermented.

No leſs doth the Cure of Intermitting Feavers ſeem to prove this our Aſſertion, whether it be Natural and Critical, or Artificial, and performed by the help of Medecines. As to the firſt, Intermitting Feavers are wont to be terminated after a twofold manner. The firſt is, when from the fits themſelves the temper of the Blood is altered, and oft-times is reduced into its natural diſpoſition. For when in every coming of the fit, very much of Sulphur, and aduſt Salt is burnt out, and exhaled by Sweat, the Liquor of the Blood, by that means becomes more temperate, and leſs torrid: wherefore, oftentimes this Diſeaſe is cured, at ſix or ſeven periods, and of its own accord ceaſes; but if it be longer protracted, and that the Blood being ſomewhat changed from the ſharp and bilous temper or diſpoſition, is not reſtored to its natural temper, ſometimes it degenerates into an acid, watery, and alſo pontic or ſaltiſh temper, from whence a long Tertian Feaver paſſes into a Quotidian, or a Quartan; alſo oftentimes, becauſe the Blood is greatly depraved, by the long continuance of this Feaver, the Jaundies, or the Scurvy, or the Cachexia follow. The other manner, whereby this Diſeaſe is terminated, is, when the change of the Air, or the Country, brings a notable alteration of the Blood; for ſo Feavers begun at the times of the Equinoxes, are ended about the time of the Solſtices; alſo the ſick, travelling into another Region, often grow well.

As to the Cure of it, by the Inſtitutions of the Medecines, it uſes to be done two ways, *viz.* Empirically, and Dogmatically; and in this Diſeaſe, Empirical Remedies, ſought from Quack-ſalvers, and old Women, are more eſteemed, and oftentimes do more than the Preſcriptions of Phyſicians, adminiſtred after the exact method of Curing.

Empirical Remedies, which are ſaid to cure Intermitting Feavers or Agues, are of that ſort, which drive away the approaching fit, without any Evacuation, and are either taken inwardly, or are outwardly applied, where the Pulſes chiefly beat, *viz.* For the moſt part, they are bound either to the region of the Heart, or to the Hand-wriſts, or to the Soles of the Feet; theſe ſometimes are ſo commonly known to help, that ſome have warranted the ſudden Cure of this Diſeaſe, by theſe Remedies, under the pain of ſome forfeiture: Wherefore it is worth our enquiry, how theſe operate, and by what way or means they ſtop the Feaveriſh acceſſions. It is clear, Firſt, that thoſe which are outwardly applied, do immediately impart force and action to the Blood and Spirits; and when they drive away the fit, by preventing, without the evacuation of humor, or any matter of neceſſity, the reaſon of this effect conſiſts only in this, that by the uſe of theſe ſort of Medecines, the turgeſcency or ſwelling up of the Blood, with the feaveriſh matter, and Fermentation are ſtopp'd; to wit, from the Medecine tied about the Body, certain little Bodies or *Effluvia* are communicated to the Blood, which do very much fix and bind together the particles of it, or alſo, as it were precipitate them, by fuſing and ſhaking them; and by either way, the ſpontaneous growing hot of the Blood, is hindred; as when cold water is put into a boiling Pot, or as when Vinegar, or Alum is flung into new and working Beer, preſently Fermention ceaſes. and the Liquor acquires a new taſte and conſiſtency, whereby it becomes fit to be drunk, as if it had been kept to ripen along time. But that theſe Ague-ſtoppers do work after this manner, it is plainly ſeen, becauſe thoſe which are of principal note, do excel in a Styptic, and binding force, or elſe with a precipitating virtue; hence Sea-ſalt, Nitre, Sal-gemmæ, the Juice of Plantane, Shepherds-burſe, any binding herbs pounded with Vinegar, and the like, bound to the wriſts, the root of Yarrow, Tormentil, alſo Camphire hung about the neck, are ſaid to take away this Diſeaſe: yea, thoſe alſo which are taken inwardly, are of the ſame rank; the Juice of Plantan, Red-Roſe water, Alum, for that they fix, and conſtrain the Blood, a decoction of Piper, Sal Armoniac, or of Wormwood, Spirit of Vitriol, alſo a ſudden paſſion of anger, or fear, foraſmuch as they precipitate the Blood, by fuſing and ſhaking it, do oftentimes hinder the Agues approach: even as the concuſſion, and ſhaking much any Liquor, or the infuſion of aſtringent things into it, hinder its ſpontaneous effervescency and rage. It is uſual with ſome Empiricks, for the cure of Agues, to tie a little knot in a Linnen Rag, or a piece of Paper rolled up, ſo ſtrictly to the wriſts, preſſing hard upon the beating of the Pulſe, that the circulation of the Blood is ſomewhat hindred, and by this means, the Aguiſh fit coming on, is

driven

driven away. Very many by this way, I have known to be cured of a tedious ſickneſs; the reaſon of which ſeems to be, that whilſt the Blood is hindred from its motion in any part, it grows more tumultuous in the other parts; and ſo by this perturbation, ſtirred up in the whole Blood, the ſpontaneous Effervency of the Liquor, being about to follow, is hindred. But that the fit, by this, or any other means, being once hindred, does not afterwards eaſily return, the reaſon is, becauſe, if this feaveriſh and depraved matter be contained longer in the Blood, it is afterwards cocted, and in ſome meaſure ripened; and therefore the Blood does not (as before) altogether pervert, either this, or the proviſion coming to it anew, but begins to digeſt and aſſimilate it; beſides, when the fit is once ſtopp'd, its cuſtom is broke, by the inſtinct of which alone, Nature oftentimes repeats thoſe her Errors: for, as when it has once made a fault, it is wont more readily to do ill after the ſame way; ſo when it once omits its fault, it more eaſily accuſtoms it ſelf to do better.

The dogmatical Cure is inſtituted for the moſt part, by Vomitory and Purging Medicines, alſo with the letting of Blood; with which the ſick are miſerably tormented, and the Diſeaſe ſeldom profligated or driven away, that deſervedly, this Diſtemper is called the Shame of Phyſicians; but Tertian Feavers are ſometimes carried away by a Vomit given juſt before the coming of the fit, which indeed happens (as I think) for the reaſon before mentioned. For I have ſaid, That the cauſe of a Tertian Feaver, is an evil diſpoſition of the Blood, whereby it paſſes into a ſowr and bilous Nature; and therefore it doth not rightly aſſimilate the nutritious Juice brought to it, but changes it into a fermentative Matter; wherefore, if the Bile or Choler be copiouſly drawn forth of the Blood, that Choleric and hot Intemperance is very much taken away, and that fermentative power ceaſes of it ſelf; But Emetick Medecines do chiefly perform this; for if they operate ſtrongly, a Convulſion is not only brought to the bottom of the Ventricle, but alſo the *Duodenum*, with an inverſe motion, is drawn together towards the Pylorus, and the Choler by a continual thruſting forward, being ſqueez'd forth from the Choleduct paſſage, is poured into the Ventricle, which is preſently caſt out by Vomit; which being copiouſly performed, the galliſh Bladder is almoſt emptied, and after that, it becomes a receptacle, that draws forth, and ſeparates the bilous humor, or the Particles of aduſt Sulphur and Salt plentifully poured into the Blood; the next fit ſometimes is by this means prevented, not becauſe the Mine of the Diſeaſe is extirpated by Vomit, but becauſe an Evacuation and Motion is excited, contrary to the Feaveriſh motion, and for that reaſon, the ſpontaneous Effervеſcency of the Blood is prevented. Alſo by this means, ſometimes the Diſeaſe is taken away after the Fit, becauſe this way, the Blood is fully cleared from the bilous humor. It is worthy obſervation, that in a Quartan Feaver, Vomits profit nothing, and ſeldom in a Tertian, unleſs adminiſtred preſently at the beginning, whilſt the Feaveriſh diſpoſition is yet light, and not fully confirmed.

Concerning Intermitting Feavers in general, there yet remain ſome Irregulars of them, to be explicated, which vary from the wonted manner: for unleſs theſe unuſual appearances be ſolved, this our Hypotheſis will ſeem to be defective, and to halt in one part. Firſt therefore, they are wont ſometimes to lack the cold or ſhaking fit. This intermitting Feaver is frequent in Autumn, whoſe fits are wont to exerciſe the ſick only with heat. and that moſt violent, and in many they come with great Vomiting, but no Sweat or Cold; then after four or five periods, upon the coming on of the fit, the ſick are wont to be chill, and preſently after to quake, and in the declination to ſweat: The reaſon of this was, becauſe, from the very hot Summer, the conſtitution of the Blood was become ſharp, and very much burnt; wherefore the Particles of the crude Juice, being commixed with it, were preſently torrified, or made hot, and ſcorched; that they did not at firſt, like (new Beer) grow hot with an Acrimony, and then afterwards blaze forth; but a turgeſcency being ſtirred up (like dry wood laid upon a fire) preſently took fire, and broke forth into flames; but afterwards, the Liquor of the Blood being fired by ſeveral fits, became leſs torrid, that the depraved alible Juice was not preſently torrified, but paſſed into a Nitrous matter, and fermenting with ſharpneſs, which at firſt ſwelling up, induced the ſenſe of Cold to the whole Body. When the cold fit was begun, for the moſt part Sweat concluded it: which indeed hapned, becauſe the Blood being made more watery, is more eaſily reſolved into vapour, with the Feaveriſh matter, even as a watery Liquor is more eaſily drawn forth by diſtillation, than what is Oily, or of a more thick conſiſtency.

It often happens, in the declination of this Diſeaſe, when the Fits begin to leſſen, that the ſenſe of Cold and ſhaking, by litle and little are diminiſhed, and at length vaniſh, and the Fit only troubles the ſick with a light burning: The reaſon of which is, becauſe at this time, the Blood being ſomewhat reſtored towards its natural ſtate, begins to concoct and ripen the crude Juice; ſo that a great part of it is aſſimilated: but ſome Excrements being heaped together in the Blood, bring forth as yet a light burning: but when the Feaveriſh Particles do not participate of the Nitrous Acrimony, the Fermentation of the Blood is induced without any ſhivering, by which, what was extraneous, burns forth, is either ſubdued, or carried forth of doors. Sometimes alſo, in the declination of this Diſeaſe, the Fits appear without any burning, only

with

with a light cold: The reaſon of which is, becauſe the Morbifick matter, being rather Nitrous, than Sulphureous, when it is in Flux, does ſomewhat blunt the Natural Heat; and by that means is diſſipated, and vaniſhes, without any great deflagration.

There is yet a great doubt concerning the intervals of the periods, which ſometimes ſeem to be double in the ſame Feaver, that the firſt Acceſſion anſwers to the third, and either perhaps comes in the morning; and again the ſecond to the fourth, and both happen in the Evening; and ſo forward: wherefore, the Feaver bearing this figure, is wont to be named a double Tertian, or Quartan, of which it doth not eaſily appear, how they ſhould be done, if the fits depend upon the evil diſpoſition of the Bloud, and from thence on a Congeſtion to a Turgeſcency of the depraved nouriſhing Juice: for which cauſe, they commonly affirm, that this double figure is ſtirred up, or draws its original from a double Neſt, or Mine; but to me it ſeems moſt likely, that in this caſe, ſometimes it happens for the Feaver to be ſimple, and of one kind, alſo its types or figures to be alike, and all congruous one to another, but the error to ariſe, becauſe the interſtitia of the periods, are not computed by hours, but days: For when as, the beginnings of the fits are diſtant one from another, not exactly twenty four hours, but either ſixteen, or thirty hours, in a Quotidian; and in a Tertian, not forty eight, but forty, or fifty ſix, more or leſs, or thereabouts; it comes to paſs, that every other fit, happens before, and the others after Noon. To which alſo may be added, that the different manner of eating, which the ſick uſe very often, produces great inequalities of figures: that ſometimes the fit is redoubled twice in a day, as I have often obſerved in Cachectical men, or full of ill humors, and living diſorderly: but it doth not ſeldom happen, that Intermitting Feavers, repeat fits, which do neither obſerve the ſame diſtance, nor bear altogether the figure of the ſame mode. I have many times obſerved in a Quartan Feaver, that beſides the ſet comings or Acceſſions, returning on the fourth day, about the ſame hour; ſome wandring and uncertain fits, did infeſt the ſick; that ſometimes on the day preceding, the wonted fit, ſometimes on that following it, another fit (tho' lighter) was excited anew, with Shivering, Heat, and Sweat, exactly like the figure of an Intermitting Feaver; and nevertheleſs, the primary Acceſſion returned at its accuſtomed time. This, for the moſt part, is wont to happen, either from Diet evilly inſtituted, chiefly from ſurfeit, and drinking of Wine; or elſe from Medicines wrongfully adminiſtred: The reaſon of which (unleſs I am deceived) conſiſts in this: The Maſs of Bloud, being wont to be filled to a ſwelling up, with the Fermentative matter, at a ſet time, often, by reaſon of ſome errors in eating and drinking, heaps up more matter, than can be eaſily diſſipated in one fit; and when it unequally Cooks the ſame Fermentative matter, it often happens, that it firſt ſhakes off its ſuperfluous, or more thin part, as it were by a certain skirmiſh, in a more light fit, but diſpels the more thick, (after the primary Acceſſion) as yet remaining in the Bloud, by a Feaveriſh Fermentation ariſing anew. And when the fits, in an Intermitting Feaver, redouble after this manner, either become more remiſs, for that the ſame matter in either, is only divided; and eventilated by two acceſſions. Beſides, when this Fermentative Matter, or Nutritious Juice, depraved in its circulation, is continued, partly in the Arteries and Veins, with the Bloud, and partly in the Nervous ſtock, and ſolid parts, it may happen, that both humors do not ferment at once, but a great part of one may be diſperſed in one fit, and then a great part of the other, in another fit.

Chap. IV.

Of the kinds of Intermitting Feavers; and firſt of a Tertian.

WE ſhall eaſily accommodate to our Hypotheſis, delivered in the former Chapter, concerning the nature and beginning of Intermitting Feavers, all the Phænomena which belong to it, and the reaſons of them. But as thoſe which are of this ſort, do not obſerve the ſame ſpace of Intermiſſion, or of return, and their figures, as to the appearances of their ſigns and ſymptoms, do not altogether happen after the ſame manner; therefore according to the diverſities of theſe, and eſpecially from the diſtance of the fits, the various ſpecies and differences of Intermitting Feavers, are aſſigned. The chiefeſt diviſion of them is, into Tertian, Quotidian, and Quartan: We ſhall here remark the chief things worthy of note concerning each of them.

It is called a Tertian Feaver, not which is accompliſhed at the diſtance of three days; but incluſively from the day in which one Fit begins, from thence the other returns on the third. In the mean time, if the Fits be ſometimes longer, *viz.* protracted almoſt to twenty four hours, and the Remiſſions anticipated alſo by their acceſſions, or comings of the Fits, the ſpace is oftentimes

times leſs by a night and a day. This Diſeaſe is commonly diſtinguiſhed into exquiſite and ſpurious; The exquiſite or exact Tertian Feaver is, which begins with a vehement ſhaking, to which ſucceeds a ſharp and biting heat, which goes off in ſweat, and its Fit is finiſhed in twelve hours, and that the perfect intermiſſion follows; In the ſpurious or baſtard Tertain, the cold and heat are more remiſs, but the Fit is often extended beyond twelve hours, yea, often to eighteen or twenty. Theſe differ as to the various diſpoſition of the Bloud, which is in the former more torrid and ſharp; therefore perverts the alible Juice from Crudity, towards an aduſtion, wherefore a more vehement Effervescency is ſtirred up; but as the matter more equally burns forth, it is ſooner finiſhed. In the latter, beſides the aduſtion, the Blood abounds with too much ſerous humidity, wherefore, the nouriſhing Juice degenerates into a Crude matter, and therefore leſs apt to be overcome, and to burn forth; wherefore, its Fit is gentler, and more unequal, but is not finiſhed but in a longer ſpace.

The Eſſence therefore of a Tertian Feaver conſiſts in this; That the Bloud (like Beer brew'd with too high dry'd Mault) being too ſharp, and torrid, does not rightly ſubdue, and ripen the alible Juice, which is taken in from crude things eaten, but very much perverts it into a nitrous, ſulphureous matter; with which, when the maſs of Bloud is filled to a ſwelling up, like new Beer ſtopp'd up in Bottles, it conceives an heat: From the flux of this nitrous matter, which blunts the heat, and vital ſpirits, and pulls the nervous parts, firſt the cold, with ſhaking is excited; then the vital ſpirit getting ſtrength again, this matter growing hot in the Bloud, begins to be ſubdued, and inkindled in the heart; from whoſe deflagration, an intenſe heat is diffuſed through the whole body; then its reliques being ſeparated, and involved with *ſerum*, are ſent away by ſweat.

This torrid Conſtitution of the Bloud, conſiſts in this, That 'tis impregnated more than it ought, with Particles of Sulphur and Salt; wherefore, the Procatartick Cauſes, which diſpoſe to this Diſeaſe, are an hot and bilous temperament, a youthful age, hot diet, as an immoderate uſe of Wine and ſpiced Meats, but eſpecially in the Spring, and autumnal ſeaſons of the year, when the Bloud (as all Vegetables) is apt to flower, and to ferment of its own accord. By reaſon of theſe occaſions, the Liquor of the Bloud, is wont to be throughly roaſted, and to be changed into a cholerick temper: and when it departs from its natural Diſpoſition, ſo much, that it perverts the nutritious Juice, into a matter plainly Fermentative, the beginning of this Feaver is induced; which ſometimes happens from this intemperance, being leiſurely increaſed and brought to the height; but more frequently, an evident cauſe raiſes up this diſpoſition into act, and we aſcribe the origine of this Diſeaſe to ſome notable Accident. Wherefore, lying on the Ground, or taking cold after ſweating, or tranſpiration being any ways hindred; alſo a Surfit, or a perturbation of the Stomach, from any thing inordinately eaten; and laſtly, What things ſoever ſtir up an immoderate heat in the Bloud, bring the lurking diſpoſition of this Diſeaſe into act: for that, from every ſuch occaſion, the nutritious Juice, being heaped in the Blood, and ſomewhat depraved, conceives a Flux, and departing from the reſt of the Bloud, ferments with a nitrous ſharpneſs, then being inkindled and ſhaken by the Spirit, and vital heat, it induces the Fit, with a very ſtrong burning.

A Tertian Feaver, is wont to be more frequent in the Spring, at which time, the Bloud is livelier and richer, and therefore more fitted for this kind of Feaveriſh diſtemper. If this Feaver being taken, be ended within a moderate time, 'tis commonly ſaid to be a Medicine, rather than a Diſeaſe; which is partly true, becauſe, by this means, the impurities of the Bloud burn out, the obſtructions of the Viſcera are diſcharged, and in truth the whole Body is ventilated, ſo that 'tis wholly freed from every excrementitious matter, and the ſeminary of growing Diſeaſes. But if this Diſeaſe be long protracted, it becomes the cauſe of many Sickneſſes, and of a long want of Health. For from hence the maſs of the Bloud is very much deprived of the vital Spirit, and (like Wine too much fermented) in a manner grows lifeleſs: wherefore the Jaundice, Scurvy, or Cachexia, follow this Feaver, being long e'er it be cured. For by its frequent fits, the vital ſpirit very much evaporates, and becauſe it is but little reſtored by things eaten, the Bloud therefore becomes weaker, and almoſt without life: In the mean time, the particles of Salt and Sulphur, are carried forth more, and exalted; from whence, the Bloud is made ſharp, and ſalt, and ſo more unfit for Circulation and Tranſpiration.

Moreover, This Diſeaſe being long protracted, oftentimes changes its Figure, and from a Tertian Feaver, becomes either a Quotidian, or ſometimes a Quartan: then ſometimes from either, it returns into a Tertian. The reaſon of this is, the diſpoſition of the Bloud being variouſly changed: which at firſt being ſharp, and bilous, had perverted the nutritious Juice, by that means, that it ariſe to a fulneſs of ſwelling up on the third day; afterwards, by the frequent Deflagration, becoming leſs ſharp, or in truth more wateriſh, it grows far weaker as to its Conſtitution, ſo that it doth very little, or not at all aſſimulate the nouriſhable humor, and ripen it, and by that means, the increaſe of the Fermentative Matter is made ſooner, and the Fits return daily: or elſe, the Bloud from a ſharp and bilous intemperance, (the conſtitution of the Heaven, or the Year, bringing on this alteration) is changed into an auſtere, or ſaltiſh,

and

and therefore more ſlowly perverts the nouriſhing Juice, and the increaſe of the Feaveriſh Matter, gathering together more ſlowly, it doth not conceive the Fits till on the fourth day: but if either, by the means of Phyſick or Dyet, the temper of the Bloud is reduced from either Dyſcraſie, towards a bilous, the periods alſo are altered, and they reſume the figure of a Tertian.

Certain Symptoms are wont to come upon a Tertian Feaver, which are commonly eſteemed for the Criſis of this Diſeaſe; and in truth ſometimes, theſe appearing, the Diſtemper either clearly ceaſes, or begins to abate of its wonted fierceneſs. But theſe kind of ſigns, are chiefly theſe three, *viz.* The Eryſipelas, or an Eruption of Pimples in the Lips, the Yellow Jaundice, and an Inflammation, or ſwelling ſuddenly excited, in this or that part of the Body: very often there happens after three or four Fits to the ſick, little Ulcers with a cruſty Scab, to break forth about the Lips, and altho' there be no coming away of any Matter, in all the Body beſide, yet from hence they preſage, that the Feaver is about to depart, which ſometimes the event proves true. But indeed ſometimes, I have obſerved, that the hoped for effect has not ſucceeded, but that the Feaver pertinaciouſly, and for a long while hath afflicted them, when their Lips have been broken out. But as to what reſpects this Symptom, it ſeems to ariſe, for that the Bloud having got a more free Diaphoreſis, it not only thruſts forth adoors, the more thin and ſmoaky Recrements, but alſo the more thick; and when the ſame, in other parts more eaſily exhale through the more open Pores, they ſtick in their paſſage about the Lips, by reaſon of the skin being more ſtrictly bound together; and becauſe the vaporous matter abounds in particles of aduſt Salt, and Sulphur, being fixed in the skin, it there hinders Circulation, and therefore induces Puſtles, and little Ulcers; perhaps the more hot breath, which is breathed forth from the mouth, and noſtrils, may contribute ſomething to this Diſtemper, foraſmuch as it ſcorches, and burns the Blood, and Juices flowing thither: wherefore, it may be ſaid, That this eruption of Puſtles, denotes only a more full Diaphoreſis in the whole, by which, the more thick, as well as the thin Recrements of the aduſt Bloud, evaporate forth of dores. For I have known in ſome, from a Tertian Feaver, little welks like the ſmall Pox to break out in their whole body, that if by this more plentiful Ventilation, as it were a purging, the Blood be ſo freed, that it recovers its priſtine diſpoſition, the Feaver is cured: But if (as ſometimes it happens) ſome Recrements, tho' more thick, break forth, yet others ſtay within, and ſtill cheriſh the Feaveriſh diſpoſition, thoſe little Ulcers, argue only a greater taint of the Bloud, and pertinacy of the Diſeaſe, therefore it may be obſerved, when that ſcabs break out in the lips, if the Feaver does not preſently abate, that it will be more grievous and tedious for the future.

Sometimes the yellow Jaundice comes upon a Tertian Feaver, and cures it; (which *Hippocrates* has alſo taken notice of) the reaſon of which is, becauſe, when the Bloud has got a ſharp or bilous diſpoſition; that therefore it had perverted the alible Juice, and from thence had heaped together excrementitious matter, it is oftentimes freed by that Dyſcraſie, when by a ſudden Secretion, the recrements of aduſt Salt and Sulphur, are more plentiful purged forth. This the Choleduct Veſſels being irritated by Phyſick, or of their own accord, and ſo pouring out plentifully the Bile, from the Bloud, do often perform: becauſe Vomiting, Purging, and eſpecially a Diarrhea or Lask, very much conduce to the Cure of this Diſeaſe, yea ſometimes, the Bloud it ſelf, putting forth of its own accord, thruſts forth the bilous recrements, at its off-ſcourings, and in the circulating puts them forth in the skin, and ſo inducing the yellow Jaundice, cures this Feaver.

When an Inflammation, (as ſometimes 'tis wont) comes upon this Diſtemper, the Ague is commonly ſaid to fall down into the part diſtempered with the Tumor. But that by ſuch a breaking forth, this Diſeaſe is cured, 'tis no wonder; becauſe the Bloud by this means continually lays aſide out of his boſom, the proviſion of the degenerate nutritious Juice, and transfers it to the diſtempered part; and therefore, the degenerate and fermentative matter in the maſs of Blood, does not eaſily ariſe to a fulneſs of ſwelling up: wherefore, the Belly being perpetually looſe, hath by degrees helped ſome, for that the Blood by this means, readily caſts forth its burthen, now growing low, and not having a more full increaſe yielded to it: ſometimes alſo, a Deafneſs ſuddenly ariſing, the Tertian Feaver has preſently ceaſed, to wit, by reaſon of a continual tranſlation of the Feaveriſh Matter, from the boſom of the Bloud, into the head.

If that the Tertian Feaver, within a ſhort time, neither by the free accord of Nature, declines by degrees, that it doth clearly ceaſe within ſeven or ten periods, nor is cured by any of the aforeſaid means, nor is removed by the help of Medicine, but that after ten or twelve fits, the ſick are ſtill grievouſly afflicted, it will be a very hard task to cure it: becauſe the Bloud, from the continual heaping of the Feaveriſh matter, and by the frequent burnings, becomes at length ſo depraved, that it concocts nothing truly for the nouriſhment of the body, and for the ſuſtaining its ſtrength; neither is it able to ſhake throughly out of its boſom, the impurities and excrements, whereby the Diſeaſe may make a Criſis or ſeparation, but in truth, the ſame growing in ſtrength every day, the Blood, beſides its Dyſcraſie or evil diſpoſition, begins to be

hurt ſomewhat in its mixture; wherefore, more frequent fits infeſt them, nor does a perfect Remiſſion come between, but that the ſick being very weak and languiſhing, are almoſt continually Feaveriſh, with thirſt and heat: when it is come to this paſs, unleſs they are ſuccour'd by remedies from Art, or that the change of the Place, and Air, bring timely help, this Diſeaſe often ends in death.

As to its Cure: the method of healing is commonly directed to this one ſcope, to wit, that the mine of the Diſeaſe may be extirpated, and that the Feaveriſh matter may be eradicated out of our Body, without any cheriſher remaining, or fear of relapſing; wherefore Vomits and Purges are diligently inſtituted, which when profiting nothing to the cure, but that the Patients ſtrength is very much broken, the ſick are left by the Phyſicians, and the buſineſs is wholly committed to Nature. The Intentions (as it ſeems to me) ought to be of this ſort: Firſt, a reſtitution of the Bloud, to its natural Temper. Secondly, a prevention of the depravation of the nouriſhing Juice, as much as may be. Thirdly, an Inhibition of the Feaveriſh Fermentation, that the fit may not be excited. And theſe Indications take place, not only in a Tertian Feaver, but in any other intermitting Feaver beſides: which yet are to be performed, not by the ſame ways and remedies, but by ſeveral, according to the diverſity of the Diſeaſe, of the condition of the ſick, and of the ſymptoms chiefly urging. However in the curing of this Diſeaſe, there is more to be attributed to Nature, and to a good order of Diet, or way of Living, than to Phyſick.

1. Concerning the firſt Intention; to wit, that the Bloud may be reduced to its natural Temper, Vomits, letting of Bloud, and Purging are of great uſe: eſpecially, if they be celebrated in the beginning of the Diſeaſe. *Vomitories* help, both for that they purge the Ventricle, that the firſt Concoction may be better performed, and by that means the nouriſhing Chyme may be more purely ſupplied, for matter of the Bloud; but chiefly, for that by plentifully preſſing forth the Bile, from the Choleduct paſſage, they empty the Galliſh bag, as by that means, the Bile is poured forth more full from the maſs of Bloud; and ſo the Bloud is purified, from the recrements of aduſt Salt and Sulphur. The opening of a Vein, cools and ventilates the Blood, as by that means, 'tis leſs torrified, or ſcorched, and is circulated more freely in the Veſſels, without danger of burning. Alſo Purging plentifully draws forth, and by provoking expreſſes, or ſqueezes out, the Bile, from the galliſh Veſſels, and conſequently from the maſs of Blood. For this end, (to wit, the reduction of the Bloud) Digeſtives bring help, the more temperate Vinegars, or Acetous things, foraſmuch as they fuſe, and alter the Bloud, and do attemper its fervor. Sometimes alſo, the change of the Soil, and Air, notably amends the evil conſtitution of the Blood, before all other Remedies whatſoever.

The ſecond Intention, is excellently performed, by Diet, and an exact manner of living; which in this Diſeaſe ought to be ſlender and ſparing: wherefore it is commonly ſaid, Starving is the beſt Remedy for this Diſeaſe: and it appears by common experience, that by a more ſpare eating, the coming of the Ague fit, is very often prolonged, beyond its wonted cuſtom. There are eſpecially two things to be obſerved, concerning Eating and Drinking: The firſt, that the food be ſlender, that nothing Sulphureous or Spirituous be given, for ſo the Conflagration of the Bloud will be leſſened; then ſecondly, that the fit approaching, or urging, nothing of Aliment be taken, wherefore, in faſting the fit is lighter, and ſooner finiſhed.

As to the third thing propoſed; the Inhibition of the Feaveriſh fit, is inſtituted by Remedies, which ſtay the Fermentation of the Bloud. But tho' this Remedy ſeems Empirical, and unmethodical, and very failable to Phyſicians, yet I have found theſe Feavers to be very often cured by this means, when Medicines have profited nothing: What they are, and by what means, without the ſuſpicion of Witchcraft, they afford help, for the curing this Diſeaſe, is before noted. We ſhall here only advertiſe you, that the uſe of theſe is moſt profitable after Phyſick, and opening a Vein, if there be need of it; and unleſs theſe be rightly performed before-hand, thoſe other rarely ſtop the fit. But Vomiting, Purging, and breathing a Vein, unleſs they be preſently celebrated after the beginning, yield little help, yea, more often are wont to hinder: For whilſt the Bloud is ſtrong in vital ſpirit, its evil diſpoſition, may with eaſie labour be corrected, or amended: wherefore if the Bile, about the beginning, be copiouſly drawn forth, or the Bloud eventilated, it is reduced to its natural Complexion; but afterwards, in the progreſs of this Diſeaſe (the Spirit being now very much exhauſted, and the Salt and Sulphur too much exalted) if theſe kind of Evacuations be adminiſtred, they do more debilitate the diſpoſition of the Blood: and therefore it is clear by obſervation, that the Tertian Feaver, is rarely or never cured, by theſe Remedies late adminiſtred, and often paſſes into a Quotidian. I my ſelf have known ſome, in the Spring time, being ſtrong in very good health, from a more ſtrong Emetick taken for prevention ſake, cauſing a violence by the Evacuation, to have preſently fallen into a Tertian Feaver; and others, for ſome time cured of this Feaver, when they had taken a ſtrong Purge, for the carrying away of the remains of the Feaveriſh matter, upon it to have fallen into a Relapſe. It may be readily ſaid, that the mine of the Diſeaſe, being before at quiet, was ſtirred up, and brought into Act, after this manner by the Medicine: But if you conſider this thing rightly,

rightly, it may rather be ſaid, that from the ſtrong Medicine, the diſpoſition of the Bloud was very much hurt, and when at firſt it was prone to a bilous Dyſcraſie, that it hardly did aſſimilate the alible Juice, from this evident cauſe, it forthwith degenerated, that it wholly perverted the Nutriment, into a Fermentative matter, and ſo conceived the Feaveriſh diſpoſition. It is a common opinion, that a Tertian Feaver can ſcarce be cured, without a Vomit, wherefore ſome Medicaſters, are wont under the pretext of the neceſſity, to give to all whatſoever, labouring with this diſeaſe (though languiſhing and weak) an Emetick Medecine not without great danger of life: and thoſe whom they judge wholly unfit for ſuch a Medecine, they leave as not eaſily curable, to Nature. But (as I have often found the contrary by experience) this ſort of practice is evilly inſtituted; yea, I rather judge, for the curing of a Tertian Feaver, that Vomits are rarely or never to be required, unleſs in a ſtrong Body, and very eaſily prone to vomiting, and when the Ventricle happens to be burdened with excrementitious matter; but inſtead of it, that a gentle Purge, by which the load of the humors may be pleaſantly brought away, may be of better uſe; becauſe a Purge in this caſe, doth the ſame thing as a Vomit, to wit, it evacuates the Choleduct Veſſels, that the Bile being plentifully exhauſted from the Blood, the Feaveriſh Dyſcraſie is mended. But when the galliſh humor, being emptied forth into the Ventricle, is caſt out upwards, from thence there is great hurt brought to the Stomach, and a mighty perturbation excited in the whole Body: But if that humor be enticed downwards by a gentle Purge, it is ſent forth of doors without any trouble. Then, if to a gentle Purge, once or twice repeated, be added a very ſlender Diet, without fleſh, it often anſwers the preſervatory Indication, that there needs no other Remedies, for the taking away the cauſe of this Diſeaſe; but that theſe being rightly performed, ſhall render beneficial thoſe things, which being either inwardly taken, or outwardly applied, ſtop the Feaveriſh acceſſion. By this ſort of plain and eaſie inſtitution of Medicine, *viz.* A Purge of the infuſion of Senna, and Rhubarb, a ſlender Diet, and a Febrifuge or Ague-reſiſting Topick, laid either to the Wriſts, or the Breaſt, I have known vey often, and in a very ſhort time, Tertian Feavers cured, without the uſe of any other deſtroying Phyſick; yea, a thin Diet only, with Amulets timely adminiſtred, hath very happily cured Big-belli'd women, and alſo very weak old men, whoſe ſtrength could not bear Purging. I have ſo often made trial of this method, with good ſucceſs, that I doubt not, but that a Tertian Feaver may as eaſily be cured, as any other Diſeaſe, if it be at the beginning handled after this manner, *viz.* before the temper of the Blood be more hurt, by an evil manner of Diet, or by Medicine untowardly adminiſtred. For the truth of this thing I will relate this following Hiſtory.

A certain Noble young man, indued with a bilous temper, had caught an intermitting Tertian Feaver; upon the approach of the Fit, he vomited forth much yellow and greeniſh Choler, then he was troubled moſt grievouſly, for many hours, with a great pain of the Heart, and moſt ſtrong Heat and Thirſt. On the day of the Intermiſſion there was taken from this perſon, with whom I was by chance, by my preſcription, eight ounces of Blood, and in the Afternoon was given an Emollient Clyſter, he alſo uſed a moſt ſlender Diet (*viz.* only made of Barly) He took every night going to ſleep, this Opiate, *viz.* Conſerve of Roſes vitriolated, half a dram, of Diaſcordium a ſcruple, alſo every morning of the Salt of Wormwood a ſcruple, in a ſpoonful of the Juice of Orange; but when theſe did not ſucceed (for the fit returned ſomewhat more remiſs, but with cruel Vomiting, as at firſt,) beſides, for that this ſick perſon extreamly abhorr'd a Vomitory Medecine (becauſe not long before this, from a very gentle Emetick, he had vomited almoſt thirty times, until being diſtempered with the Cramp and Convulſions, he was brought into great weakneſs, with hazard of his Life) therefore, the day following the aforeſaid Fit, I gave him a Potion of an infuſion of Senna, Rhubarb, and yellow Sanders, with Sa't of Wormwood, in Spring-water, by which he was purged ten times with eaſe: In the Morning after, and three hours before he expected the Fit, I put to his wriſts an Ague-reſiſting Medecine, and took from him ſix ounces of Blood, by which means he miſt his Feaveriſh Fit, and then being again purged after the ſame manner, became perfectly well.

If that the Tertian Feaver, by reaſon of the evil Conſtitution of the ſick, or becauſe of Errors in Diet, or committed by Phyſick, hath more deeply rooted it ſelf, that after a long Sickneſs, the Fits ſtill grow worſe, and the ſick extreamly languiſh, with want of Strength, Thirſt, and almoſt continual Heat, want of Appetite, Wakings, weak Pulſe, high-coloured Urine, and very full of Contents, the Curatory Method ought to be a little otherwiſe inſtituted; In this caſe, firſt it is to be endeavoured, that the Dyſcraſie of the Blood may be taken away; wherefore the ſick are to be fed with ſlender Aliments only, as Barly-Broth, or Grewel, with opening Roots boiled in it (fleſh-Broth being wholly laid aſide) the Belly is to be kept looſe (if need be) with the uſe of emollient Clyſters, beſides (Purges being omitted) only Digeſtive Medecines, which fuſe the Blood, and bring away gently the ſerous Impurities by Urine, alſo comforting Remedies, which corroborate the Viſcera, and cheriſh the Spirits, are chiefly to be inſiſted on. To this end, Apozems are fitly to be prepared, of Herbs, and Roots gently Diuretic; alſo Opiats help very much, of temperate Conſerves, with Sal Nitre, or

the fixed Salt of Herbs, with ſhelly Powders, and the Spirit of Vitriol mixed together. When the diſpoſition of the Blood is ſomewhat mended, that the Urine is clearer, and leſs coloured, alſo ſleep quieter, with a remiſſion of thirſt, and heat following, then may be profitably adminiſtred Remedies to ſtop the Feaveriſh Fit: wherefore Ague-reſiſting Amulets may be applied to the Wriſts or to the Soles of the Feet; alſo the Powder of Peruvian Bark, or of ſomething inſtead of it, or alſo of the Barks of the Aſh-Tree, Tamariſk, or Gentian, with Salts mixed with them, and drunk in white Wine; after the comings of the Fits are taken away, and the ſick begin to get ſtrength, and deſire food, and in ſome meaſure to digeſt it, gentle Purges may be of uſe; but let the ſick ſtill abſtain from a more plentiful Diet, or participating of Fleſh, and they will ſhortly after recover perfect Health without any violent Purge or Phlebotomy.

CHAP. V.

Of the Quotidian Intermitting Feaver.

BEcauſe of its Affinity to the Tertian Feaver, and likeneſs of Fits, the Quotidian (or daily) Feaver comes next, *viz.* whoſe Acceſſion is wont to return every day. It is the Opinion of ſome, that this ſort of Feaver is only a double Tertian, and doth ariſe from a diſperſed matter, having gotten a twofold Neſt; to which I cannot aſſent; and I ſuppoſe its beginning is to be attributed to a peculiar Dyſcraſie of the Blood. In this the Symptoms of Cold and Heat are more remiſs, but its fit is longer continued, and oftentimes it is wont to laſt eighteen or twenty hours: This Feaver for the moſt part follows a Tertian; for when the Vital Spirit is very much flown away, by the frequent deflagration of the Blood, and (the Feaveriſh diſpoſition ſtill remaining) the Blood is made weaker, it doth not concoct the nouriſhing Juice, or ripen it, but perverts almoſt the whole into a fermentative matter; wherefore its comes ſooner to its increaſe, and is gathered together to a plenitude of ſwelling up, within double the time, than at firſt. But becauſe the congeſted matter participates equally of crudity and aduſtion, therefore the heat of the burning is leſſer, and more unequal, and (like green wood laid on the fire) ſlowly burns; for which reaſon the Fit endures longer.

Sometimes it happens, that a Quotidian Feaver, doth ariſe without a Tertian going before, *viz.* when a Feaveriſh diſpoſition falls upon a Cacochymic Body, or full of evil humors, and ſtuffed with depraved Juices; for then the Blood, being poor in Spirits, perverts in a greater meaſure the nutritious Juice, and in a ſhorter time gathers to a fulneſs of ſwelling up: But that which begins an every days Ague, oftentimes changes its figure, and becomes a Tertian; juſt as a Tertian often goes into a Quotidian, becauſe between theſe Feavers, and their Cauſes, there is a great vicinity; and the conſtitution of the Blood being a little changed, it makes a tranſition from one to another. A Quotidian Intermitting Feaver is not ſo eaſily cured as a Tertian: For whether it comes at firſt ſimple, or follows upon another intermitting Feaver, it is ſtill excited from a ſtronger cauſe, and argues a greater dyſcraſie of the Blood, which will not preſently give way to Remedies. But alſo, if this Feaver be of long continuance, or comes upon another Chronical Diſeaſe, it has moſt often adjoyned to it, beſides the taint of the Blood, the infirmities of the Inwards: to wit, the Blood being ſpoiled, eaſily affixeth its impurities by degrees heaped up, on the Viſcera, whilſt it paſſes through their Meanders: from hence it is, that in a Quotidian Feaver, the weight of the Ventricle, an extenſion of the Hyponchondria, Obſtructions, or Tumors, now of the Liver, now of the Spleen, or Meſentery, are joyned together; but theſe kind of Diſtempers, are not the cauſe of the Feaver (as is commonly believed) but only its product. Wherefore, in this Feaver, beſides the ſimple method of Cure, which is ſhewn in the Tertian, many other intentions or coindications, come under conſideration: to wit, that the Ventricle be cleanſed from its load of humors, the ſtuffings of the Inwards freed, Infirmities corroborated; and that together with theſe, the Dyſcraſie of the Blood may be mended, and the Acceſſions of the Feaver may be reſtrained, muſt by all means be endeavoured; from whence, by reaſon of theſe kind of various intentions, we come to the Cure by a longer way: In this caſe, Vomits (if ſtrength will bear them) are of benefit before all other Medecines: alſo Purges, whereby the aſſiduous ſupply of Excrementitious matter may be drawn forth, are often to be repeated: Beſides theſe, Digeſtive Remedies, Openers of Obſtructions, ſuch as reſtore the Ferment of the Viſcera and Blood, and correct their evil diſpoſitions, are frequently to be adminiſtred. Wherefore, the fixed Salts of Herbs, and their Extracts, Acid Spirits of Minerals, and ſometimes Preparations of Steel, do very much help: concerning theſe main

main things, the Task will be hard, when by reaſon of the manifold evil, many things are to be done together, yet by reaſon of the aſſiduity of the Feaveriſh fit, there is leiſure for the ſick to uſe few only. In Diſtempers ſo complicated, though the reaſon of the Method requires the impediments to be firſt removed, and then to cure the Diſeaſe, yet I have known this kind of Feaver, beſet with many other Diſtempers, in a Body full of Humors, often cured, without Method, and by an Empirical way, *viz.* after a light proviſion of the whole, Ague-reſiſting Remedies being outwardly applied, have at firſt ſtopped the Feaveriſh Fit, that then there was time, for the curing the other Diſtempers, and more happy occaſions of healing were granted. I lately viſited a Noble Lady, who being long indued with a Cachectical habit of Body, a Month after her Lying in, being weak and languiſhing, was taken with a Quotidian Intermitting Feaver; after ſix or ſeven fits of it, her ſtrength was ſo much caſt down, that ſhe could ſcarce riſe out of, or ſit up in her Bed; nor able to take never ſo little Food, though very ſlender, but upon it, moſt grievous moleſtations were raiſed up in her Stomach; beſides, the Region of her Ventricle, and left Hypochondrium, was wholly beſet, with a hard ſhining tumor, and cruelly painful, by reaſon of her ſtrength being mightily caſt down, there was no place left for Evacuation, but the uſe of Clyſters; alſo her Stomach being very weak, loathed all other Remedies, unleſs very grateful, and only in a very ſmall quantity. In this difficult caſe, circumſcribed between narrow limits of Curing, I counſelled theſe few things, to wit, that twice in day, ſhe ſhould take this mixture, *viz.* The Magiſterial Water of Earth-worms two ounces, of Elixir Proprietatis twelve drops. Moreover, I ordered to be applied to her Ventricle, a Fomentation, of the Leaves of Sea-Wormwood, Centaury, Southernwood, with the Roots of Gentian, boiled in White-Wine, in an open Veſſel: alſo, that after the Fomentation, a Cake of Toſted Bread, and dipped in the ſame Liquor, ſhould be worn upon her Stomach; beſides, Ague-reſiſting Medicines were ordered for her wriſts; and with theſe Remedies only, ſhe miſt her Ague-Fit, on the third day, and remained free from it afterwards; then by the Uſe of Chalybeat Remedies, ſhe became perfectly well, within a ſhort time.

Chap. VI.

Of a Quartan Feaver.

In a Quartan Feaver, the period is longer than in the reſt; to wit, which is extended to the fourth day incluſively; alſo its continuance uſes to be longer, and its cure harder: becauſe this Diſeaſe is protracted for many Months, yea, oftentimes for years, and ſeldom, or ſcarce at all, is cured by Medecines.

The Fit, for the moſt part, begins with cold and ſhaking, to which a very troubleſom heat ſucceeds, but more remiſs than in a Tertian: Sweat for the moſt part concludes the Fit. At the firſt coming of the Diſeaſe, the Fits are more grievous, and very infeſtous, and keep the ſick in their Beds; yea, they make them loſe their ſtrength, and vigor of Body: But afterwards, the trouble is more eaſily born, ſo that the fits are ſuffered out of bed, and ſometimes in a Journey, or being about any buſineſs. If it continue long, it induces the Scurvy, or Hypochondriac Diſtemper, and involves men in an unhealthful condition.

The Cauſes which diſpoſe to this Diſeaſe, are firſt, the Conſtituion of the Soil and Air, becauſe this Diſtemper is proper to the Fall of the Leaf, or Autumn, that you rarely find this Feaver to begin but about that time: alſo in ſome places, eſpecially about the Sea-coaſts, this uſes to be general, or common to the Region, and to come upon thoſe living there, or Strangers coming thither from elſewhere. A declining Age, which is paſt its Achme or height, alſo a Melancholick Temper, and which, by reaſon of an ill manner of living, is obnoxious to the Hypochondriac Diſtemper, cauſe this: beſides, long Feavers of another kind, and Chronical Diſeaſes, often paſs into a Quartan Feaver.

According to theſe Poſitions, and rightly weighed, it may be ſaid, that a Quartan Feaver, even as the other intermitting Feavers, depends upon a vicious diſpoſition of the Blood; to wit, becauſe the nutritious Juice, being by degrees dilated into the Veſſels, is perverted into a a fermentative matter; and the effervescency of this, heaped up even to fulneſs of ſwelling over, conſtitutes the Fit of the Quartan Feaver. But as in this Feaver, there are ſome things, which are peculiar from the reſt, we will enquire what kind of Dyſcraſie of the Blood it is in this Diſeaſe, diſtinct from the others, and by what means it excites the very remarkable Symptoms.

The

The Opinion which is commonly had concerning this thing, is very far from Truth; almoſt by the conſent of all, the Eſſence and beginning of a Quartan Feaver, is aſcribed to a Melancholic humor, heaped up ſomewhere in the firſt paſſages, and there periodically putrifying. Inſtead of this, we affirm, that in this Diſeaſe, the Liquor of the Blood doth paſs from a ſweet, ſpirituous, and balſamick, into an acid, and ſomewhat auſtere nature, like Wine growing ſowr; to wit, there is too great a want of Spirits, and the Terreſtrial, or Tartareous part of the Blood (which conſiſts chiefly of Salt and Earth) is too much exalted, and being carried forth into a Flux, induces the ſourneſs of the maſs of Blood. Even as Beer being diſturbed by Thunder, and infected with a troubled Lee or Dregs, grow ſowr. The Blood, after this manner degenerated from its native diſpoſition, doth not rightly dreſs the alible Juice, and aſſimilate it to it ſelf, but perverts it into an extraneous matter; with which, when it is ſatisfied to a fulneſs, in the Veſſels, and the nervous parts are watered by the Juice, from thence ariſing, a Flux of this matter, and as it were a ſpontaneous effervescency follows, by which indeed, the Feaveriſh fit is induced, with ſhivering and heat, as is wont to be in a Tertian.

In a Quartan Feaver, the periods have longer intervals, becauſe, when the Dyſcraſie of the Blood is become ſowriſh, and therefore leſs violent and hot, it perverts the alible Juice without ſtrife or tumult: wherefore, it aſſimilates ſome of it, and the depravation of the reſt, does not ſo far recede from its natural ſtate, as in a Tertian; and from hence its congeſtion to a plenitude, is made longer, and almoſt in another half of that time, in which a Tertian riſes up to a Turgeſcency: And therefore, thoſe taken with this Feaver, are indifferently well, and are ſtrong; which is a ſign, that the nutritious Juice is leſs depraved; alſo the Fits are made without cruel burning, becauſe the nutritious humor is perverted into a fermentative matter, without great aduſtion.

But why this Diſeaſe is ſo hard to be cured, and ſo pertinaciouſly infeſts the ſick, the cauſe is, the Melancholic Conſtitution of the Blood, which is not eaſily to be taken away, and yields almoſt to no Remedies. The Cholerick diſpoſition of the Blood is mended by the frequent Deflagration, and ceaſes often of its own accord, even as too rich Wines are depreſſed by their own growing hot, and are wont to be reduced into their due ſtate; but this Melancholick Dyſcraſie of the Blood, in which, with a want and defect of Spirits, Salt and Earth are too much exalted (as when Wines grow ſowr) is moſt hard to be reſtored, and is almoſt of the ſame labour and difficulty, as to put again Life, and a Vinous Spirit into Vinegar: For that the Blood, depraved after this manner, may be reſtored, it will be needful, that its whole maſs ſhould be volatilized, and as it were made Spiritual anew: wherefore, in this caſe, Evacuations profit not a jot; yea, by more depauperating the Blood, oftentimes the ſtrength is caſt down, beyond help: but they had need to exalt, and make volatile what is fixed, and to promote a Tranſpiration, or Spiritualization in the whole Maſs of Blood: From hence it is, that in this Diſeaſe, the change of the Air and Region, moſt often brings help, before all other Remedies; for the Spring following oftentimes takes away thoſe Quartan Feavers that had ariſen the Autumn before; which without doubt happens, becauſe the changed condition of the Air is wont to alter for the better, the evil diſpoſition of the Blood: alſo for the ſame reaſon, the change of the place, moſt often cures this Diſtemper, inexpugnable to all Phyſick.

If it be demanded, wherefore this Diſeaſe chiefly begins in the Autumn, and rarely in the Spring, or Summer time; I ſay, the Autumnal time doth moſt fitly produce this kind of Feaveriſh diſpoſition of the Blood; for when very much of the Spirit and Sulphur hath flown away by the Summers heat, and that what is left begins to be bound up by the Cold; the Liquor of the Blood (as Wine growing ſowr by too much heat) eaſily degenerates into a ſaltiſh, and acidulous or ſharp Nature: This alſo, the Sea-Air, by infecting the Blood and Spirits with Saline Vapours falling on them, eaſily procures: yea, alſo the affinity of this Diſeaſe, with the Scurvy and Hypochondriac Diſtemper, plainly ſhews, the evil diſpoſition of the Blood to be in fault, whereby it becomes ſalt, and earthy, with the want of Spirit.

Concerning Quartan Feavers, the laſt year was ſo abundantly fruitful of Obſervations, that many might collect by ocular inſpection, whatever belong to this Diſeaſe; for when the moſt hot Summer was paſt, about the end of it an Epidemical Feaver (of which in another place you ſhall have a deſcription) followed; then the Autumn coming on, when that Diſeaſe had ceaſed, a Quartan Feaver began very much to rage; that in very many places the fourth part of the People was taken with it: neither did it only infeſt old men, ſplenetick and melancholick men, but of every Age and Temper, alſo Infants, Children, and young Men ordinarily; which was clearly a ſign, that this Diſtemper had drawn its Riſe, not from a Melancholick Humor, heaped up, by the default of the Spleen, but from the Dyſcraſie of the Blood, brought in, through the intemperance of the Year; for the Maſs of Blood, after too great heats, even as Wines after immoderate effervescencies, was made fit to grow ſomewhat ſowr, or to get an auſtere diſpoſition, and ſo alſo prone to this ſort of Feaver, as is already ſhewn.

If the Remedies, which for the curing of this, have been made trial of, both by Phyſicians and Empiricks, were collected together, their deſcription would ſwell into a great Volume; but

but although there is inſtituted a manifold proviſion of Medecine, againſt this Evil, yet very few are cured in the Autumn. In ſome, about the beginning of their ſickneſs, before the Diſeaſe has taken too deep root, a Vomit hath brought help; but in moſt, all manner of Catharticks, tho' an hundred times repeated, have profited nothing. In whom the evil had deeply implanted it ſelf, the ſick received no help, from the moſt ſtudied Medicines made uſe of all the Autumn. But when at this time, I perceived the ordinary method of Medicine, was adminiſtred in vain, I propoſed to a Noble Virgin, requiring a ſudden Cure, by any means, to be performed, that if ſhe would indure a Flux at the Mouth, for ſome days, from a Mineral Medicine, by that means, it might be hoped, that the Diſeaſe would be profligated. When ſhe had readily aſſented to this, I gave her a gentle, and very ſafe Medicine, by which a light ſpitting only was provoked, and that finiſhed within twelve days: As ſoon as the Salivation began, ſhe miſt her fits, but at thoſe times they were wont to come, ſhe felt a perturbation in her whole Body, with an oppreſſion of the Heart, and dread of ſwooning, but after the ſpitting was finiſhed, ſhe appear'd very well; and when again after two months ſpace, ſhe was troubled with ſome light fits of this Diſeaſe, from an Emetick Powder, twice or thrice taken, ſhe was wholly cured without relapſing.

After the winter Solſtice, this Diſeaſe began to rage leſs, and to ceaſe in ſome of its own accord, and in many others, to be eaſily expung'd by the uſe of Phyſick: becauſe at this time, the Dyſcraſie of the Blood, contracted by the Summers heat, is wont to be blotted out leiſurely, by reaſon of the cold of the Winter, and the maſs of Bloud growing old, as it were to put off its old ſpoils, and to be reduced towards its natural ſtate. But thoſe who were of a melancholick temper, or had their Viſcera, and eſpecially the Spleen, evilly affected, or that uſed an ill manner of Diet, received no change at this Tropick, but to the next period of the year, *viz.* to the vernal Equinox, or the Spring, kept the Diſeaſe; and then in moſt, the Blood being either reſtored of it ſelf, or its intemperance more eaſily mended by the uſe of Remedies, this Diſtemper was ſeen to be overcome: But in the mean time, many old men, and ſuch as were full of evil humors, or otherways unhealthy, ordinarily died, in all that ſpace of time, of this Diſeaſe; alſo ſome liv'd, who could not ſhake off its yoak, tho' the Summer Solſtice were paſt. But altho' very many had labour'd with this Feaver, as it were Epidemical, almoſt through the whole year, yet none (that I know) contracted it firſt in the Spring, and very few grew well of it during the Autumn, that in truth, I do not doubt, the Dyſcraſie of the Bloud, to be the cauſe of this, and the cure to conſiſt in the change of it.

The Remedies, which moſt often brought help, (as appeared at leaſt to our obſervation) were of this ſort, which did reſtrain the Feaveriſh fit: for the evils of the diſpoſition of the Bloud, being ſomewhat mended, by the time of the year, being changed, if now the habitual cuſtom of the fits were broken off, Nature recollected her ſelf, and eaſily recover'd the priſtine ſtate of health, by her own endeavour. And this kind of intention, (to wit, the inhibition of the fits) though ſometimes performed by Vomits, given a little before the coming of the fit, (for theſe did not rarely ſtop the Feaveriſh motion of the Bloud, by raiſing up another motion contrary to this) yet this Indication is far more certainly, and indeed happily effected, by the uſe of thoſe kind of Medicines, which do not altogether evacuate from the Viſcera, but induce, either a certain fixation to the Blood, or a precipitation of the Feaveriſh matter, for a time. Wherefore, thoſe whom I undertook to cure in the Spring, and afterwards; I handled (and in moſt with good ſucceſs) with this method; a proviſion being made of the whole, ſometimes with an Emetic Medicine, ſometimes with a Solutive; I was wont three hours before the fit, to lay a peculiar Ague-Medicine to the wriſts, and together, to give them to drink in Sack, an Ague-reſiſting Powder, and to order the ſick to be kept in a Bed in a gentle ſweat: It ſeldom hapned, but at the firſt, or ſecond time, the Feaveriſh fit, was by this means reſtrained, and then, by the ſame Remedy, ſometimes reiterated, the Diſeaſe at laſt wholly ceaſed. To this kind of practice, (beſides our experience) the uſe of the Powder, of a certain Bark, brought of late from the *Indies*, ſeems to give ſome faith, and approbation; which is ſaid, moſt certainly, to cure this Diſeaſe; but the vertue, or operation of this, without any evacuation, conſiſts in this only, that it hinders the coming of the Feaveriſh fits.

Concerning this Peruvian Bark, becauſe of late it hath begun to be in uſe, there are ſome things to be ſaid, which offer themſelves to common obſervation. The common manner of exhibiting this is, that two drams of it beaten to powder, be infuſed in Sack, or White-wine, in an open Glaſs, for two hours, and then upon the coming of the fit, the Patient being put to Bed, that the Liquor and Powder be drunk up. This Potion often takes away the approaching fit, yet oftentimes tho' taken after the wonted manner, it prevents the next, however, either in the firſt, ſecond, or third period, the fit is inhibited, and the Diſeaſe ſeems to be cured, it is often wont to return, within twenty or thirty days; then this Powder being again exhibited, the Diſeaſe is for a time deferred about the ſame ſpace, and by this means, I have known many ſick of a Quartan, to have ſuffered ſome few fits only, a whole Autumn, and Winter, and ſo to have detained the enemy in his precincts, till the Spring coming on, the diſpoſition of the Bloud is altered for the better,

better, by the help of the time of year, and of other Phyſick, and ſo this diſtemper vaniſhes by degrees. Thoſe who by this means, have procured theſe frequent truces of the Quartan, have liv'd chearful, lively, and ready for any buſineſs, when otherwiſe, being weak, and pale, they were brought into languiſhment, and a vitious habit of body: ſcarce one of an hundred, hath tryed this Medicine in vain, yea, if but half, or a leſſer quantity, *viz.* the weight of but one dram, taken, it very often takes away the fits, and ſuſpends the ſame, a ſhorter ſpace only; neither is it any matter, whether it be taken in ſtrong, or ſmall Wine, unleſs with the reſpect, to the diſpoſition of the ſick: becauſe in a more hot temper, it may be profitably taken in diſtilled Water, or Whey; alſo, a clear infuſion of it, the more thick ſubſtance being caſt away, produces the like effect, but of ſhorter durance: I have taken care to reduce this Powder into Pills, with the Mucilage of Tragacanth, with a little coſt to the ſick, to be given to ſome; after what manner ſoever it is taken, unleſs to thoſe loathing and abhorring every Medicine, it cauſes no manifeſt evacuation, and takes away the fit, almoſt from all; neither is it only in a Quartan Feaver, but in the other kinds of intermitting Feavers, to wit, in every one where there is any remiſſion coming between, given with good ſucceſs. It is commonly ordered, that a gentle Purge ſhould be taken before this, but in ſome who are very weak, and keep their Beds, this Powder being taken carefully, without any previous Medicine, hath procured laudable effects. In the mean time, I will ingeniouſly confeſs, that I have not ſeen an intermitting Feaver quite cured, by this Bark, once taken: nay, rather the fits not only of a Quartan, but of a Tertian, and Quotidian Feaver, wholly overcome eaſily by other Remedies, ſeeming to be driven away by this Powder, have conſtantly return'd after a ſhort time. For this Reaſon, they who ſuppreſs intermitting Feavers, otherways eaſily curable, no neceſſity urging them, by this Medicine, for a little while, only ſeem to inſtitute a deceitful Medicine, and do no more than thoſe, who skin over a rotten Ulcer, which will ſhortly break out again; in truth, in ſome caſes, the uſe of this will be requiſite, *viz.* when by the too great aſſiduity of the fits, the ſpirits of the ſick are caſt down, truces are by this means procured, by which Nature may recollect her ſelf, and afterwards may be more able to fight againſt this potent Enemy: alſo, that a Quartan Feaver, during the Autumn and Winter, may paſs over with little trouble, this Bark is profitably adminiſtred: But thoſe, who expect a longer reſting time, from the aſſaults of this Feaver, are bid to take this Powder in greater quantity, and more often, to wit, that they ſhould take two drams, three ſeveral times one after another, whether the fits return or no; by this means, they remain longer free, yet they retain within, the Enemy ſtill, tho' aſleep.

If it be demanded, concerning the Nature of this Bark, and the vertue in ſuppreſſing the fits of Intermitting Feavers, it is not to be diſſembled, that 'tis very difficult to explicate the cauſes of theſe kind of effects, and the manner of working; becauſe there is not found as yet in any Subject, beſides, the like efficacy; but from a ſingular Experiment, a general Reaſon is not to be rightly fitted: however, from the appearances diligently Collated, we will deduce ſome Theſes in order, which may make at leaſt ſome ſteps towards, if not obtain the verity of this thing.

It is to be noted therefore, in the firſt place, that this Medicine, being inwardly taken, eſpecially exerciſeth its force and energy on the Maſs of Blood: becauſe, it does not at all irritate the Viſcera, neither cauſes in them any excretion, or trouble; beſides, whilſt it communicates its vertue to the Blood, it doth not at all put forth Anti-feaveriſh property; wherefore, not always the next following fit, but the ſecond, or the third, is prevented, by the ſame being taken: and for this reaſon, that it may ſooner affect the Blood, it is a uſual thing, to drink the Liquor, very much impregnated with the ſame Powder, for ſo its Particles are more eaſily conveyed into the Maſs of Blood. Secondly, The Vertue of this Bark, being impreſſed on the Blood, ſtays in it for ſome time, and that either ſhorter or longer, according as either a greater or leſſer portion of the Medicine was taken inwardly; for the Particles of this, being confuſed with the Blood, are a long while circulated with it, and by how much the longer they ſtay, by ſo much the more they affect its maſs, and produce a longer effect: for though Aliments, and ſome other things taken in, for that they are preſently overcome by the native heat, put off whatever they have of vertue, within ſome few hours, this being then aſſimilated, or ſent forth adoors, they ceaſe to operate: yet ſome Medicines being taken inwardly, becauſe they are not eaſily tamed, nor caſt forth of doors preſently, by an irritation ſtirred up, they remain for many days very active, and hold a long time the Juices, and the Blood, in this or that manner of Fermentation, this may be obſerved of ſome Medicines, alſo of Poyſons, and Counter-poyſons, the once or twice taking of which, for ſome days, is wont to affect our Bodies for a longer time; for 'tis an uſual thing which Cathartick Medicines, when they work little by Vomit, or Stool, to break forth after many Weeks outwardly, in Puſtles and Welks: yea, if Death be avoided, from the drinking of Poyſon, every body knows, that the virulency will lie hid, a long time in the Blood and Juices. In like manner alſo, this Powder, and perhaps very many other things inwardly taken, altho' they ſeem aſleep, yet continue to act, on the Spirits and Humors.

Thirdly

Thirdly, Altho' this Medicine acts immediately on the Bloud and Humors, yet it takes not wholly away, the Feaverish Dyscrasie, implanted in them: for, as soon as its force is consumed, and all its Particles are flown away, from the mixture of the Bloud, the Distemper being only suppressed for a time, at length rises up, and repeats its fits after its wonted manner, but forasmuch as Nature, by the space of this cessation, becomes stronger, therefore, after the Relapse, the fits (not as before) but on the third or fourth day, according to the first figure of the Disease, are wont to return.

Fourthly, It is remarked, that this Remedy, does not stop the Feaverish accessions, as the ordinary Ague-resisters or Febrifuges, by fixing, or also by fusing the Bloud; for then the next fit always, and not the second, or third following after, is prevented.

According to which positions, that we may instead of a Corollary, subjoyn some things concerning the manner it self of working, whereby this Medicine seems to act; we say, it is most likely, that when the Particles, proceeding from the same being taken, are throughly mixed with the Bloud, they compel it into a certain new Fermentation, by which, whilst the Particles of the Bloud are continually agitated, they are wholly hindred, that they cannot heap up any Excrementitious matter, or enter into Feaverish turgescencies; for, as after the biting of a mad Dog, or stinging of any venomous Creatures, the Bloud it self, and nervous Juice, are a long while impoysoned, yet lest they should conceive presently great irregularities, Counter-poysons being taken do hinder their Liquors, by retaining them in another Fermentation; the use of which, if so long continued, whilst the virulent little Bodies are quite flown away, no horrid symptom is to be feared, from that evil being contracted; but if the strength of the Remedy, being too sparingly given, be first consumed, forthwith the Venom repullulates, and the old Poyson, thought to have been exploded, is at length brought into act: by the same way, when the Bloud, having gotten a vitious disposition, perverts the Alible Juice, and whereby it might more rightly expel it, heaped together to a fulness, conceives Feaverish swellings up; this Peruvian Bark being beaten, and administred, by the Commerce of its Particles, so agitates the Bloud, tho' distempered with an evil disposition, with a new excited Fermentation, and alters it, that it in some measure concocts the nourishable Juice, and continually evaporates its Recrements, that they are not heaped together as before, into the matter of a fit: But, when the Particles of this Remedy, are wholly flown away, from the company of the Bloud, and the whole virtue consumed, the evil disposition of the Bloud, before contracted, at length rises up, and so the Feaverish fits return, after their wonted manner. Sometimes perhaps it happens, that whilst the Feaverish fits are suppressed, by the use of this Powder, by reason of the season of the Year being changed, or by the help of another Remedy, or by the endeavour of Nature it self, that Dyscrasie of the Bloud may be mended, by degrees, and so the Feaver may at length vanish, of its own accord. This I have known to happen, but very rarely, because almost with the same certainty, by which you expect the Feaverish fits to be suppressed, by that Powder, you may afterwards look for their return.

As to what appertains to the sensible qualities, with which this Bark is noted, it appears to abound with bitterness, and a certain stipticity, that it seems to the taste, to have the likeness of Savor, which is in most Counter-poysons, as the Root of Gentian, Serpentary, Contrayerva, *&c.* for what are bitter in act, are strong in excellent virtue, for the suppressing the force of preternatural Ferments; yea, the Root of Gentian, which is likest to this Bark, was in times past of famous use, for the Curing of Quartan Feavers. But now, altho' this Peruvian Powder, be the only Alexiterion or Counter-poyson, as yet found out against a Quartan Feaver, to wit, that inhibits (tho' only for a time) its fits, and of other Intermitting Feavers, yet it is not to be doubted, but that there are in the World, other Medicines extant, which are as good Ague-resisters; and it is hoped, that led by the example of this new invention, we may be excited, to the finding out the virtues of Herbs, almost as yet unknown: so, which whilst we shall insist on the trial of several, and the Empirical be joyned to the Rational Medicine, without doubt the Cures of the Quartan Ague, and of other invincible Diseases, may more happily be accomplished: which therefore I promise more willingly to this Age, or at least to the next, when being led by the Analogy of this Book, I have found out a Medicine, for the profligating of Feavers, of use not contemptible, it not being long since variously tryed, which also I am wont to give to the poorer sort, instead of something else, with good success.

CHAP. VII.

Of Continual Feavers.

A Continual Feaver is that, whoſe fit is continued for many days, without intermiſſion: It hath its times of remiſſion, and of more fierceneſs, but never of intermiſſion; the burning is now more remiſs, now more intenſe, but ſtill the ſick are in a Feaver, until by the temperament, or inſenſible growing well, the Diſeaſe is wholly cured. Concerning this, it behoves us to inquire, what Effervescency of the Blood it is, which cauſes a continual Feaver; then, by what ways, and from what cauſes, it is wont to be excited: alſo, how it differs from that, which is in Intermitting Feavers. And theſe being performed, we will deſcend to the Species of Continual Feavers.

There are many ways, by which the Blood growing hot, induces a continual Feaver, the chief of which may be reduced to theſe Heads: The firſt way is, when the more ſpirituous, and ſubtil Portion of the Blood, becomes too hot, and is diſtempered, with a certain burning, which therefore agitates the other parts of the Blood, and incites it into a certain rage, ſo that the Sulphur, or the Oily part of the Blood, is more diſſolved, and more inkindled in the Heart, alſo, for that cauſe, there is among all the Particles of the Blood, a certain ſyncriſis, contrariety, or perturbation, by which in truth, being confuſed, and put out of order, they are not able quickly to be extricated, and reduced into their former poſture, wherefore a heat and burning more than is wont to be, is ſtirred up in the whole Body: but when the Spirits are only in fault, their heat and diſorder, are wont within a ſhort ſpace, to be allayed of their own accord; therefore, this Feaver is often terminated within a day, and is rarely continued beyond three: and therefore, is called and Ephemera, or a Feaver of a day, or Synochus of more days.

2. The ſecond manner, or degree of growing hot, is when the Sulphureous or Oily part of the Blood, being too much heated, conceives a Fervor: for then, it both grows immoderately hot in the Veſſels, and being very much inkindled in the Heart, produces by its deflagration, a very ſtrong heat in the whole Body. Indeed the Blood, as to its temper, moſtly depends on the condition of the Sulphur; when by reaſon of Crudity, the Sulphur is leſs diſſolved, the Blood is made watry and cold, and is moved ſlowly in the Veſſels: but if the Sulphureous, or Oily part of the Blood, grows hot, beyond its Natural diſpoſition, preſently it becomes fierce, and improportionate with the reſt, ſo that, almoſt the whole being acted, as it were into a flame, by the Ferment of the Heart, compels the maſs of Blood to grow immoderately hot, and and to boil up. For as when Wines, indued with a rich Lee, are ſtirred up into an heat, by the too rancid Sulphur; or as Hay, laid up too wet, by reaſon of the want of Ventilation, conceives of its own accord a burning, the Particles of the Sulphur being looſned from the mixture; in like manner, when the Blood is not rightly ventilated, but being reſtrained from Evacuation, by reaſon of the admixtion of ſome hot thing, or a more plentiful ſanguification, or for ſome other cauſe, the Particles of the Sulphur begin to be thickly gathered together; preſently, all its Liquor, immoderately boils up, by the Sulphurs being looſned, and inflamed in the Heart, and this kind of Feaver is induced, which is called a putrid Synochus; notwithſtanding which appellation, tho' of many rejected, for that the Blood ſo long as it is in motion, doth not putrifie; yet foraſmuch, as in this Feaver, the mixture of the Blood, is ſomewhat looſned, by the Sulphur being too much exalted, and the maſs of its Liquor being changed, from its Natural diſpoſition, tends toward putrefaction; therefore, the term of a putrid Feaver, as hath been anciently uſed, may be ſtill, with good reaſon, retained.

3. The third degree of growing hot, (and which conſtitutes a diſtinct kind of continual Feaver) is excited, from a certain malignant, and invenomed Ferment, by which, when the maſs of the Blood is imbued, and the Spirits, and the Sulphureous part together, conceive an heat, and their burning is not ſooner appeaſed, than that either that malignant matter be conſumed, and caſt forth of doors, or elſe a certain coagulation, and as it were putrefaction, of the Blood from its corruptive venom is induced, by which, both circulation is hindred, and the Vital Spirit extinguiſhed. This malignity is wont to ariſe, either from a certain contagion received from without, or from ſome infection begotten within us; according to theſe ways the malignant Feaver, Small Pox, Meaſles, and alſo the Plague, draw their beginnings, and by their contagion, far and near ſet upon many.

There are therefore three degrees, or manners of growing hot, by which, the kinds of continual Feavers are determined. From the ſubtil portion of the Blood made hot, or the Ebullition

tion of the Spirits, the Ephemera ariſes, as alſo the Synochus of one or more days; by the Sulphureous or Oily part of the blood, being too hot and inkindled, the putrid Feaver is ſtirred up; then thirdly, upon an envenomed taint, infecting the blood, and congealing its Liquor, malignant Feavers depend. In every one of theſe, by the depravation, or rather corruption of the alible Juice, freſh carried into the blood, the various fits, inequalities, and critical motions ariſe. But before I enter upon the ſeveral kinds of a continued Feaver, it is requiſite for me, to conſider, how the growing hot of the blood, in a continual Feaver, differs from that other, which conſtitutes intermitting Feavers.

I ſay therefore, that the growing hot of the blood, in an intermitting Feaver, depends only, upon the commixtion of acertain fermentative matter, and not rightly miſcible, with the blood, and on its growing up, to a fulneſs of boiling over. Becauſe of this heat, with the blood in the Veſſels, and of the deflagration in the Heart, the fit is induced; becauſe of its growing cool, the intermiſſion follows, that in the coming between of the fits, neither the Spirits, nor Sulphur, become outragious, but the bond of the mixture being kept whole, the Liquor is circulated in the Veſſels, equally, and without trouble: on the contrary, in a continual Feaver, the diſorders of the Spirits, and of Sulphur, of either, or both together, by their proper Ebullition, alſo without the mixture of any other, ſtir up the Ebullition of the blood; wherefore there are required, for an intermiſſion, beſides the diffiation or cooling of the excrementitious matter, a deflagration of the enkindled blood, and a reduction of it to its due temper.

The Conſtitution of the blood in a continual Feaver, is of the ſame ſort as of Wines, when they grow hot upon too rich a Lee; to wit, are mighty in Spirit, and grow turgid with exalted Sulphur, and therefore they conceive a fervor, and greatly boil up of their own accord, without the mixture of any other thing. In an intermitting Feaver, the blood is moved after that manner, as Wines, when they conceive an heat, becauſe of ſomething poured to them, that is not miſcible with them: Moreover, in this Feaver, the diſpoſition of the blood is of that ſort, as of Wines, when in their decay and declination, they become ropy, unſavoury, or acid, to wit, in which the Spirit is depreſſed, that in the mean time, either Salt, or Sulphur, or both together, appear above the reſt, and infect the whole Liquor with their diſorder. An intermitting Feaver, for the moſt part is free from danger, becauſe the conſtitutive parts of the blood, although they ſhould ſomewhat change their diſpoſition, however, keep the bond of mixtuer, and whilſt they are in power, are circulated equally in the Veſſels, yea, they pervert the nutritious Juice into a matter, not altogether beſides Nature, but rather infeſting, with its fulneſs and turgeſcency. In a continual Feaver, beſides the intemperance, the mixture of the Blood, and conſtitution of the Liquor are ſomewhat looſned, and its corruption eaſily follows; wherefore this Diſeaſe often ends in death: further, the nouriſhing Juice is depraved into a matter wholly vicious, and altogether infeſtous to Nature.

CHAP. VIII.

Of the Ephemera, or Feaver for a Day.

I Have ſaid, the leaſt degree of heat, which induces a continual Feaver, is placed in the ſubtil, and ſpirituous part of the Blood, being too much agitated and heated; for this, like the Spirit of Wine, boils up on every light occaſion, and conceives a fervor, by a too great motion of the Body, or perturbation of Mind, by the ambient heat, as of the Sun or Vapors, by hot things taken inwardly, as the drinking of Wine, and the eating of Pepper'd meats, and being irritated by ſuch like. For the Spirits of the Blood eaſily take fire, and being impetuouſly moved, are not preſently appeaſed, but they move throughly other Particles of the Blood, variouſly confound and ſnatch them into a rapid and diſorderly motion; alſo from this motion of the Spirits, the Sulphur, or Oily part of the Blood is more boiled forth, ſomewhat more diſſolved, and ſomething more fully enkindled in the Heart, by which means, an intenſe heat is raiſed up, in the whole Body. But foraſmuch as Sulphur is enkindled, and inflamed only by ſmall parts, and not in the whole, that fervor of the Spirits is quickly appeaſed, and ceaſes; wherefore the Feaver which is excited by this means, for the moſt part is terminated within twenty four hours, and therefore is called an Ephemera, or a Feaver of a day. If that by reaſon of a greater heat of the Spirituous Blood, it is prolonged further, it rarely exceeds three days, and is called an Ephemera of more days, or a Synochus not putrid; but if it

ſhould happen to be lengthened beyond this time, this Feaver eaſily paſſes into a putrid, *viz.* from the daily ebullition of the Spirituous Blood, the more thick particles of the Sulphur at length begin to take fire, and involve the whole Maſs of Blood in its effervescency: even as the Spirit of Turpentine, being ſhut up in a Cucurbit, and being put into a Sand Furnace, if it be forced with a moderate heat, boils up gently, as the Blood in a Feaver of a day; but if the heat be made more ſtrong, the Liquor grows impetuouſly hot, till it breaks forth into a flame, to which the inflammation of the Blood, in a putrid Feaver, may be very aptly compared.

The Days Feaver, and Synochus ſimple, rarely begin without an evident cauſe: Beſides what hath been but now ſaid, immoderate Labour, Watchings, a ſudden paſſion of the mind, a conſtriction of the Pores, a Surfeit, alſo a Bubo or inflamed Sore, a Wound, the coming down of the Milk in Child-bearing Women, are wont to induce them: The procatartic Cauſes, which diſpoſe to this, are an hot temper of Body, an active Habit, a ſedentary Life, and diſuſe of exerciſe.

The chief beginnings of this Diſeaſe depend upon the preſence of the evident Cauſe; for either, little Bodies of extraneous heat, being confuſed with the Blood, like water boiling over the fire, make it to boil up; or this Feaver is induced, by motion, or by reaſon of tranſpiration being ſtopped; even as Wines made hot by motion, or when too cloſely ſtopped in the Ton, are put into a fervor: but what way ſoever an inflammation is firſt excited, preſently the Spirits become enraged, and being moved hither and thither, compel the Blood to boil up, and to be enlarged into a greater ſpace, with a ſpumous rarefaction; wherefore the Veſſels are diſtended, and the membranous parts halled; hence follow pain, chiefly in the Head and Loins, a ſpontaneous wearineſs, and as it were an inflation of the whole Body. If that, with the Spirit of the Blood, a certain ſulphureous part be alſo in ſome meaſure inkindled, a ſharp heat is diffuſed through the whole, the Pulſe is vehement and quick, the Urine red, alſo thirſt, watchings, and many other Symptoms infeſt, the Reaſons of which are added hereafter.

Concerning the Solution, or Criſis of the Ephemeran Feaver, and of the not putrid Synochus, three things are chiefly requiſite, *viz.* a removing of the evident cauſe; ſecondly, a ſeparation, and a ſcattering of the depraved or excrementitious matter, from the maſs of Blood: thirdly, a quieting of the parts of the Blood, and a reſtitution of them to their natural and equal motion and ſite. According as theſe ſucceed, now more ſuddenly, now more ſlowly and difficultly, this Diſeaſe is finiſhed in a ſhorter or longer time.

1. The evident cauſe, which for the moſt part is intrinſick, is eaſily removed, and the ſick are wont, preſently to avoid the preſence or aſſiduity of that thing, and do perceive a ſenſe of any thing that is hurtful; none taking a Feaver from Wine, will ſtill indulge the drinking of it, aſſoon as any one grows more than uſually hot, in a Bath, or the heat of the Sun, 'tis a trouble to them to ſtay longer.

2. As to the excrementitious Matter, which ought to be ſcattered and ſeparated from the Blood; this is either brought from without as when the Blood is infected by ſurfeit, drinking of Wine, ſitting in the Sun, or from too hot a Bath, with *Effluvia*, or little dry and fermentative Bodies; or this matter is begotten within, as when its Liquor is ſtuffed with Recrements, or aduſt Particles, from the deflagration of the Blood. Either of theſe matters ought to be ſeparated from the Blood, to be diſperſed, and either by ſweat, or inſenſible breathing forth, to be thruſt out of doors, before the Feaver be appeaſed: wherefore, whenas the pores are bound up, and tranſpiration hindred, the Ephemeran Feaver is longer protracted, and ſometimes paſſes, from a ſimple Synochus, into a putrid.

3. The evident Cauſe being removed, and this degenerate matter diſperſed, there is required for the remiſſion, a quieting, and reducing into order, the parts of the Blood; for divers Particles of the Blood, being after this manner confuſed; and by reaſon of the Feaveriſh heat carried up and down, they do not preſently get again the former order of ſituation and poſition; but it is needful that they be by degrees extricated, and by little and little reſtored, to a juſt mixture.

Although this Diſeaſe, after the removing of the evident Cauſe, for the moſt part ceaſes of its own accord, within a while, yet ſome Medicinal Remedies may be adminiſtred with good ſucceſs, eſpecially, when there is danger, leſt the Ephemeran Feaver, ſhould paſs into a putrid. The chief Intentions ſhould be, to ſuppreſs the fervor of the Blood, and to procure a more free tranſpiration; to the which conduce, firſt, a breathing of a Vein, a ſlender Diet, or rather Abſtinency, cooling Drinks, and a bringing away the filth of the belly, by Clyſters: Sleep and reſt greatly help, above all the reſt; which, if wanting, ſhould be procured in time, by Opiats, and Anodines.

Verily, although the Hiſtories, and Obſervations of thoſe, diſtempered with an Ephemeran Feaver, contain in themſelves nothing very rare; yet I ſhall ſubjoin an example or two in this place, whereby the Delineation or Type of this Diſeaſe may be illuſtrated.

A certain young Gentleman, about twenty years of Age, endued with a ſtrong habit of Body, by the immoderate drinking of ſtrong Wine, fell into a Feaveriſh diſtemper, with thirſt, heat, and with a great burning of his Præcordia; being let Blood, he drank a great quantity of fair water, and upon it preſently a plentiful ſweat following, he grew ſhortly well: In this caſe, the more thin portion of the Blood, being heated by the Spirits of Wine, fell into a rage, cauſed the whole Maſs of Blood to be ſhaken, and its frame to be looſned more than 'twas wont; and for that reaſon, that hapned to be more diſſolved, by the Ferment of the Heart, and to be as it were enkindled by the active Particles, looſned from the mixture; until the Veſſels being emptied by Phlebotomy, the raging Blood was cooled, and by the drinking of the water, its fervor was attempered; then the hot *Effluvia* being involved, together with the aduſt Matter, with a copious *Serum*, and ſent away by Sweat, the Blood at length recovered its due temper. Moreover an ingenious young man, of a ſedentary life, and alſo very much addicted to the ſtudy of Learning, when he had for ſome time exerciſed himſelf beyond his ſtrength, in the hot Sunſhine, he began to complain of the pain of his head, a want of Appetite, a heat of his Præcordia, and of a Feaveriſh diſtemper all over; to whom (for that he was wholly averſe to Phyſick) I ordered an abſtinence from all things whatſoever, unleſs from ſmall Beer and Grewel; on the ſecond day, and ſo more on the third, the Symptoms remitted, by little and little; on the fourth, he went home freed from the Feaver, without any Medecine.

Chap. IX.

Of a Putrid Feaver.

So much for a Continual Feaver, which is raiſed from the moſt ſimple heating of the Blood, or its loweſt degree of inordinate heat; that which depends on a greater degree of heat follows, *viz.* when the Oily and Sulphureous part of the Blood, being too much heated, ſwells up above meaſure, and as it were forced into a flame; and therefore from the ſimilitude, by which humid things putrifying, conceive an heat, this kind of Ebullition of the Blood, becauſe it induces an immoderate heat, is called a putrid Feaver: which Name ought to be retained without injury, becauſe that in this Feaver, the Syntheſis of the Blood (as is wont to happen in putrefying Liquors) is very much unlocked. When the Spirits only grow enraged, (as in an Ephemera) the frame of the Blood is ſomewhat ſet open, and looſned, that it is more diſſolved, by the Ferment of the Heart, than is wont, and more Particles than naturally uſe to do, leap forth, and diffuſe a more intenſe heat; but yet the mixture of the Liquor, as to its chief parts, is conſerved. But when the Sulphureous matter taking fire, grows hot above meaſure, the bond of the mixture, for the greateſt part, is looſed, that its Principles are almoſt wholly drawn away, by the Ferment of the Heart, and the active Particles, being looſned from the mixture, break forth as it were into a flame. Wherefore, the Liquor of the Blood being after this manner rarified in the Heart, and as it were enkindled, is from thence carried through the Veſſels, with a moſt rapid motion, and diſperſes very many *Effluvia* of heat, from its deflagration. Hence, the whole maſs of Blood (like water put over the fire) continually, boiling, diſtends the Veſſels, pulls the Brain and Nervous parts, raiſes up Convulſions, and pains in them, very much deſtroys the Vital Spirits with its heat, waſtes the Ferments of the Bowels, hinders the Offices of Concoction and Diſpenſation, often depraves the nouriſhing Juice, deſtinated for the Nervous ſtock, that from thence exceeding great diſorders of the Animal Spirits follow; yea almoſt perverts the whole œconomy of Nature.

The courſe of this Diſeaſe ſhews it ſelf after this manner; It rarely begins without a procatartic cauſe, or previous diſpoſition: to wit, the Sulphureous or Oily part of the Blood, is firſt too much carried forth, and exalted beyond its due tenor, which afterwards, either of its own accord (like Hay not eventilated) begins to grow hot, or by the coming of an evident cauſe, it is forced into a preternatural heat. But when it grows turgid in the firſt place, by reaſon of the admixtion of a crude Juice with the Blood, now a ſhivering, now heat infeſts, which ſhew themſelves unequally, like Fire which is covered with green wood, ſends forth now ſmoke, now flame: But at length, the fire glowing more largely, as here the victor fire ſpreads it ſelf abroad, ſo there (ſooner than ſaid) the whole maſs of Blood is inflamed, and is urged at once with heat, and a moſt ſwift motion; nor is this immoderate heat of the Blood appeaſed, before its active Particles being looſned from the mixture, and then ſucceſſively inkindled in the Heart, are wholly burned out, which doth not happen, but in the ſpace of many days. And then at length this Feaver ceaſes, when the remaining Liquor of the Blood, the Spirit and Sulphur being very much conſumed, being made lifeleſs and poor, is fit only for a weak and ſmall

Fer-

Fermentation. From this kind of deflagration of the Blood, and alſo of the alible Juice (by the ſame fire burnt out) the recrements, or little Bodies of torrifi'd matter, are heaped up in the Blood, which yet do more promote its fervor and ebullition, and for a time increaſe the Feaveriſh diſtemper. After the blood hath very much burned forth, and theſe kind of little bodies are gathered together to a fulneſs of ſwelling up, the vital Spirit endeavors a ſeparation, and tries to concoct, and to overcome (what it may) theſe aduſt recrements, and then, having put a great many of them into a ſwelling up, a Flux being riſen, ſtrives to ſhut them wholly out. And indeed, in the ſubaction and ſecluſion of this matter, chiefly conſiſts the event of this Diſeaſe; for if the vital Spirit being ſtrong, the bloody Humor (when it hath ſufficiently burned forth, and ſhall be freed from theſe aduſt particles) ſhould recover its priſtine tenor, whereby it is made fit for motion, and a due fermentation in the heart, the ſick tends towards health; but if by a long deflagration, and an inextricable confuſion of the morbific matter, the liquor of the Blood, being wanting of Spirits, and more pure Sulphur, or thoſe ſame (by the impure mixture growing ill) being as it were put under the yoke, is rendred ſo lifeleſs, that it is not any longer rarified by the ferment of the Heart, or enkindled, by degrees its heat and motion, together with Life it ſelf decays.

The procatartick Cauſes, which diſpoſe to this Diſeaſe, are, a hot and humid Temper, an active habit of Body, a youthful Age, the Spring time, or Summer ſeaſon, a high and rich Diet, beſides the often drinking of rich Wines, a ſedentary and idle Life, a Body full of groſs Humors, and ſtuffed with vicious Juices; but above all the reſt, it appears by obſervation, that the frequent letting of Blood, renders men more apt to Feavers; wherefore it is commonly ſaid, from whom blood is once drawn, that unleſs they do the ſame every year, they are prone to a Feaver. The reaſon of this is (unleſs I am deceived) by the frequent letting of blood, the Sulphur is more copiouſly gathered together in the Maſs of blood; in the mean time, the Salt (which ſhould bridle it, and hinder it from raging) by this means is drawn away; for the blood, the older it grows, becomes ſo much the more ſalt, the Salt of all the Elements not evaporating. But by how much the more the Blood abounds in Salt, by ſo much the leſs it abounds in Sulphur; for Salt eats and conſumes the Sulphur, and makes it evaporate: wherefore they who are lean, and abound with a ſalt blood, are leſs prone to Feavers. But when by the letting of blood, the ancient blood is drawn forth, in its ſtead another more rich, and more impregnated with Sulphur, is ſubſtituted; ſo that it becomes leſs ſalt, and more ſulphureous. Hence it is, that thoſe who often let blood, are not only prone to Feavers, but alſo are wont to grow fat, becauſe of the blood's being more impregnated with ſulphureous Juice.

The evident Cauſes which deduce the latent diſpoſition of this Feaver into act, are of the ſame ſort, which procure an Ephemeran Feaver, and ſimple Synochus; in this rank chiefly come, Tranſpiration being hindred, and Surfetting. By reaſon of the *Effluvia* being reſtrained, the Maſs of the blood being increaſed in bulk grows turgid, and conceives a Fervor, as it were from a certain Ferment, inſpired anew, and cruelly boils up; from thence, preſently the pores are more obſtructed, by the infartion of the *Effluvia*, and the frame of the Liquor being looſned, the particles of the Sulphur exuberating in the blood, leap forth from the mixture, and are inflamed by the ferment of the Heart, as it were by fire put to them, and ſo they enkindle a very intenſe Feaver. But from a Surfeit, both an immoderate fermentation is induced in the blood, and alſo a nitrous ſulphureous matter, apt for aduſtion, and an inkindling is conveyed, as it were food, to the burning blood.

In this Feaver, four times or ſeaſons are to be obſerved, in which, as it were ſo many poſts, or ſpaces, its courſe is performed: Theſe are then, the Beginning, the Augmentation, the Height, and Declination. Theſe are wont to be finiſhed in ſome ſooner, in others more ſlowly, or in a longer time. The beginning ought to be computed, from the time the blood begins to be made hot, and its Sulphur to conceive a burning, until the ardors and burnings are diffuſed, through the whole maſs of blood. The Increaſe or Augmentation, is from the time, that the blood being made hot, and inkindled through the whole, burns forth for ſome time, and its maſs is aggravated with the Recrements, or burnt Particles, which increaſe the fermentation. The ſtate, or ſtanding of the Diſeaſe, is, when (after the blood has ſufficiently burned forth, and its burning now remits) the long vexed blood, like a noble Wreſtler, when his Adverſary is a little yielding, recollecting all his ſtrength, endeavors a bringing under, and a ſeparation of that aduſt matter, with which it is filled to a plenitude, and alſo a Criſis or ſeparation being once or oftner attempted, an expulſion of it forth of doors. The Declination ſucceeds after the Criſis or Secretion, in which the blood grows leſs hot, with a languiſhing fire, and either (the vital Spirit being as yet ſtrong) overcomes what is left of that aduſt and extraneous matter, and by degrees puts it forth, until it is reſtored to its former vigor; or, whilſt the ſame Spirit is too much depreſſed, the Liquor of the blood is ſtill ſtuffed with aduſt Recrements, and therefore becomes troubled and depauperated, that it neither aſſimilates the nouriſhing Juice, nor is made fit for an accenſion in the heart, for the ſuſtaining the Lamp of Life.

1. When

1. When therefore any one is taken with a putrid Feaver, the firſt aſſault is for the moſt part accompanied with a ſhivering or horror: for when the Bloud begins to grow hot, there is a flux made, and a ſwelling up of the crude Juice, freſhly gathered together in the Veſſels, even as in the fit of an intermitting Feaver, heat, and ſometimes ſweat follow, upon the ſhivering, by which, the matter of that crude Juice is inkindled, and diſperſed: afterwards, a certain remiſſion of the heat follows, but yet from the fire ſtill glowing in the Bloud, a laſſitude, and perturbation with thirſt, and waking, continually infeſt: A pain ariſes in the Head, or Loins, partly from the ebullition of the Bloud, and partly from the motion of the nervous Juice being hindred; alſo a nauſeouſneſs, or a vomiting offends the Stomach, becauſe the Bile, flowing out of the Choleduct Veſſels, is poured into it, and a Convulſion from Vapors, and from the ſharp Juice brought through the Arteries, is excited in the Stomach. In the mean time, altho' the heat be more increaſed, and inequal, it is not yet ſtrong, becauſe the Bloud as yet abounding with crude Juices, is only inkindled by parts: and therefore burns out a little, and then ceaſes, and at laſt returns; like a flame that is made by wet and moiſt ſtraw. In this condition for ſome days, the Diſeaſe remains, the Urin is more red than uſual, by reaſon of the Salt and Sulphur being more diſſolved and infected with the *ſerum*; It ſtill retains its Hypoſtaſis or ſubſtance, becauſe the Coction and aſſimilation are not altogether depraved; it appears greater than ordinary in its ſediment, which is yet eaſily ſeparated, and falls to the bottom of its own accord. At this time, they may let Bloud, and adminiſter Phyſick by Vomit, or Purge, ſo it be done without any great perturbation of the Bloud: it often happens, from theſe kinds of evacuations, timely performed, that a greater increaſe of the Diſeaſe is prevented, and the Feaver as it were killed in the ſhell. The limits of this ſtadium or ſpace, are variouſly determined, according to the temper of the ſick, and other accidents of the Diſeaſe; ſometimes, the firſt rudiments of this Feaver, are laid in a day or two; ſometimes the beginning of the Diſeaſe is extended to more; if in a corpulent Body full of Spirit, Juice, and hot Bloud, or it happen in a youthful Age, and very hot ſeaſon, if the diſpoſition to a Feaver be potent, and the evident cauſe coming thereupon be ſtrong, the Feaveriſh heat, being once begun, quickly invades all the Bloud, and on the ſecond and third day, having rooted it ſelf, the Diſeaſe ariſes to its increaſe; but if the Feaveriſh indiſpoſition, be begun in a leſs hot Body, a Phlegmatic temper, or a melancholy, and in old age, or a cold ſeaſon, the entrance is longer, and ſcarce exceeds the limits of this firſt ſtadium or ſpace, before the ſixth or ſeventh day.

2. The increaſe of this Diſeaſe, is computed from what time the burning of the Feaver hath poſſeſt the whole maſs of Bloud: that is, the Sulphur, or the Oily part of the Bloud, having been long heated, and growing fervent in parts, at length, like Hay laid up wet, breaks forth, after a long heating, all at once into a flame; the Bloud at this time cruelly boils up, and very much inkindled in the Heart, by its deflagration, diffuſes as it were a fiery heat through the whole Body, and eſpecially in the Precordia; hence the ſick complain of intolerable thirſt, beſides a pain of the Head, pertinacious wakings, and oftentimes a Delirium, Phrenſie, and Convulſive motions infeſt: all Food whatſoever is loathſom, either it is caſt up again by Vomit, or if retained, being baked by too much heat, it goes into a Feaveriſh matter; beſides, there happens a bitterneſs of the mouth, an ingrateful ſavor, a ſcurfineſs of the Tongue, a vehement and quick Pulſe, an Urin highly red, and for the moſt part troubled, full of Contents, without Hypoſtaſis or laudable ſediment; when the Bloud is at this time almoſt wholly inkindled by its deflagration, it begets great plenty of aduſt matter, (as it were aſhes remaining after a Fire) with which the *ſerum* being very much ſtuffed, renders the Urin thick, and big with Contents: Alſo the Bloud, being filled with a load of this, to a riſing up, is irritated into Critical motions, by which this Feaveriſh matter, (if it may be done) being brought under, and ſeparated, is ſhut out of doors; and indeed this ſtate of the Feaver induces that, in which a Judgment is diſcerned, between Nature and the Diſeaſe, the ſtrife being as it were brought to an æquilibrium; and therefore the evacuation, which follows from thence, is called the Criſis.

The ſtate therefore, or height of a putrid Feaver, is that time of the Diſeaſe, in which Nature endeavors a Criſis, or an expulſion of the aduſt matter, remaining after the deflagration of the Blood. To this is required, in the firſt place, that the Bloud hath now for the moſt part burned forth; becauſe in the midſt of its burning, Nature is not at leiſure for a Criſis, nor is it ever proſperouſly endeavored, nor in truth procured by Art with good ſucceſs. Secondly, That the ſpirit of the Bloud, doth firſt, by ſome means ſubdue this aduſt matter, or *Caput mortuum*, ſeparate it from the profitable, and render a period to the expulſion, for otherways, tho' a copious evacuation happens, Nature will never be free from her burthen. Thirdly, That this matter, be gathered together in ſuch a quantity, that by its turgency, it may irritate Nature to a Critical expulſion. If theſe rightly concur, a perfect Criſis of the Diſeaſe, for the moſt part ſucceeds, in which, even as in the Fits of intermitting Feavers, a Flux being ariſen, whatſoever extraneous and heterogeneous thing, is contained in the boſom of the Bloud, is exagitated, then being ſeparated, and involved with *ſerum*, it is thruſt forth of doors; when any thing of theſe is wanting, the Criſis, for the moſt part, is in vain, and not to be truſted, and rarely

cures

cures the Diſeaſe. For if in the midſt of the burning, before the Bloud hath ſufficiently burned forth, an evacuation happens, by Sweat, a Lask, Bleeding, or any other way, the aduſt matter is not all ſeparated, or elſe, if for the preſent, it be drawn away for the greateſt part, the Bloud more largely flaming out, preſently ſubſtitutes new, and will renew the Feaver again, that ſeemed to be vanquiſhed: If that this matter, not being yet overcome, nor brought to a fulneſs of riſing up, be irritated to an expulſion by Nature, an imperfect, and partial Criſis only follows; and when the firſt indeavor of excretion ſhall be in vain, rarely a perfect, and curatory ſucceeds after that one time.

The Criſis in a continual Feaver, is almoſt the ſame thing, as the Fit of the intermitting Feavers. For as in this, when the maſs of Bloud, is filled to a fulneſs of ſwelling up, with the Particles of depraved alible Juice, and fitted for maturation, there are made a Flux, ſecretion, and expulſion out of dores of that matter: ſo in a continual Feaver, from the deflagration of the Bloud, and alible Juice, very many little Bodies of aduſt matter are gathered together, with which, when the Bloud is aggravated, and is at leiſure, a little from the burning, it overcomes them, by little and little ſeparates them, and then a Flux being raiſed up, endeavors to caſt them out of dores: wherefore, as the Fits of Intermitting Feavers come not but at a ſet time, and after ſo many hours, ſo alſo the Critical motions happen from the fourth day to the fourth, or perhaps from the ſeventh day to the ſeventh, for in this kind of ſpace, the Bloud being inkindled burns forth, and with its burning makes an heap of aduſt matter, as it were aſhes, which being troubleſom to Nature by their irritation, induces Critical motions.

Therefore, what ſome affirm is not true, That the Criſes depend altogether on the influences of the Moon, and Stars, and follow their Aſpects, Quadrations, Oppoſitions, or Conjunctions: becauſe the Critical evacuations are only determined, by the gathering together, and the ſwelling up of the aduſt matter. For, as ſoon as the Bloud is at leiſure, from the deflagration, and being filled with the particle of that aduſt matter, is able in ſome meaſure to overcome, and ſeparate them, preſently a Flux, or ſwelling up being riſen, it endeavors to thruſt them forth by any way; which, for that they are eaſily to be ſeparated from the Bloud, and the breathing places of the skin are ſufficiently open, being involved with *ſerum*, are ſent away with ſweat. And this is the beſt way of the Criſis, which if it rightly ſucceeds, very often, wholly, and at one time, perfectly cures the Diſeaſe, without danger of relapſe. To this next, follows the Criſis, which is endeavoured by the Hemorrhage or bleeding at Noſe; for this matter, as it were the flowring, being moved with the Bloud, (if it be not caſt forth by ſweat, by reaſon of a leſs free tranſpiration) is transferred from the heart, into ſome remote part, and frequently is caſt into the Head, by the impetuous rapture of the Bloud; where, if a paſſage be open, from the private holes opening into the noſtrils, the morbific matter, leaps forth of dores, with a portion of the Bloud. But otherways being oftentimes fixed in the Brain, brings a phrenſie, delirium, or other grievous and tedious Diſeaſes of the Head; yea, 'tis to be obſerved, that almoſt in all continual Feavers whatſoever, when they are hardly or imperfectly cured, ſo that the Bloud is infected, for a long time with the Feaveriſh matter or aduſt recrements, that from thence, the nervous Juice (as it ſeems) contracting an Infection, pertinacious Diſtempers; to wit, Watchings, alſo Deliriums, Tremblings, Convulſive motions, and long adhering weakneſs of the nervous parts follow. Alſo, there are other ways of Criſis, by which Nature endeavors, not at once and wholly, but by little and little, and by parts, to expel the Feaveriſh matter; now by Urin, now by Vomit, or Stool, now by breakings forth, and buboes, or biles; by what way ſoever, that it may be done with a good event, it is required, that the deflagration of the Blood be paſt, and that the aduſt matter be concocted, and rendred fit to be ſeparated.

The ſtate or ſtanding of the Diſeaſe, is therefore not one, and ſimple, nor always happens after the ſame manner, but with a various difference of ſymptoms, and tending to far different events. But by a prudent Phyſician, a Prognoſtication is expedient to be given, in what ſpace of time, the Diſeaſe will come to its height or ſtanding, and what end it will have.

If the Feaver be vehement from the beginning, and ſuddenly invades the whole maſs of Bloud with a burning; if it urges conſtantly, and equally without any remiſſion, with a ferocity of ſymptoms; for the moſt part, the Bloud will ſo much burn forth, in the ſpace of four days, that the aduſt matter, will ariſe to a fulneſs of ſwelling up, for the making a Criſis. But if its beginnings are more ſlow, and the accenſion of the Bloud often interrupted, the Feaver will come to its *achme* or height, about the ſeventh day. If it ſhould begin yet more remiſs, the ſtanding of the Diſeaſe is wont to be drawn out, to the Eleventh or Fourteenth day. In the mean time it is to be noted, that as the Fits of Intermitting Feavers return at ſet times, ſo the Critical motions in continual Feavers, (but for the moſt part they obſerve the fourth day:) for altho' the Criſis may be perfectly prorogued to the fourteenth, ſeventeenth, or perhaps the twentieth day, becauſe all things, requiſite to the full curing of the Diſeaſe, do

do not ſooner concur; yet in the time betwixt, more light motions happen, by which the Feaveriſh matter ariſing leiſurely, to an increaſe, is a little emptied, and as it were cut off by parts, until Nature may be able to enter upon its more full diſcuſſion; but when the great proviſion of the aduſt matter, in the burning Bloud, is heaped up in the Veſſels, Nature, unleſs otherways diſturbed, on every fourth day, being tyred with the plenty of matter, trys to ſhake off part of its burthen, by a certain ſwelling up: wherefore, for the moſt part, the Critical motions happen on the fourth, ſeventh, eleventh, and fourteenth days, not by the direction of the Planets, but by reaſon of the neceſſity of Nature.

As to the event, whether the Criſis ſhall be good or not, certain fore-knowledges are taken, from the ſtrength of the ſick, the Pulſe, Urine, and other ſigns, and concourſe of ſymptoms: If the ſick appear with ſome ſtrength, the fire of the Feaver urging, hath a ſtrong and equal Pulſe, if the Urine be of a moderate conſiſtency with ſome ſediment, with a ſeparation of the Contents, and eaſily falling to the bottom, if the Diſeaſe ſhall make its progreſs, without great Vomiting, Watchings, Phrenſie, Convulſive motions, and ſuſpition of malignity, the ſtanding will be laudable, and to be expected with a good Criſis: if the contrary to theſe happen, *viz.* that preſently ſtrength is caſt down, and that the ſick is obnoxious to frequent Swoonings, Convulſions, a delirium, with a weak intermitting or unequal Pulſe, if pertinacious watchings, intollerable thirſt, and Vomiting continually infeſt; if the Urine be thick and troubled, without ſediment, or ſinking down of the parts, if, the burning yet troubling, Nature is provoked to critical evacuations, a very dangerous ſtate of the Diſeaſe is imminent, nor may there be hoped for any thing of good from the Criſis.

Concerning the Criſis of a Putrid Feaver, we will here ſubjoyn a particular Prognoſtication, in which, though the things, which from the beginning did appear, might promiſe a moſt deſired event, a very deadly one is imminent; I have often obſerved, in a Putrid Feaver, which begins ſlowly, and with a ſmall burning, if the Urine be red, and when rendred preſently troubled, and thick, which is not precipitated, neither by the cold, nor of its own accord, puts down a ſediment, and if at the ſame time, the ſick lie for many days without ſleep, tho' quiet, and that they toſs not themſelves up and down, their condition is in danger: and the ſuſpition will be more, if in the mean time, they are neither troubled with a ſtrong Feaver, nor infeſted with thirſt, or with a very troubleſom heat; becauſe thoſe diſtempered after this manner, are incident for the moſt part, about the ſtate of the Diſeaſe, to a Delirium, Convulſive motions, and oftentimes fall into madneſs, from which they are quickly caſt into death; and when theſe ſymptoms ariſe, the Urine is altered, from a thick and red, into a thin and more pale Urine. It ſeems in this caſe, the maſs of Bloud, being taken with the Feaver, not to grow turgid, ſo with Sulphur exalted to the height, as Wines or Beer are wont in their Effervеſcencies; but (the Salt, and the terreſtrial Lee or Dregs, being ſtirred together with the Sulphur) to be affected after the ſame way, as Wines and Beer, being ſuddenly diſturbed with Thunder, and growing ſour; wherefore, altho' the Bloud does not preſently conceive an immoderate heat from the Feaver, yet its diſpoſition being changed, it wholly depraves the Juice deſtinated to the Brain, and Nervous parts, and therefore about the beginning of the Feaver, pertinacious watchings happen, then the ſtate growing urgent, the œconomy of the whole Nervous ſtock is perverted. Melancholick perſons are moſt obnoxious to theſe ſort of Feavers, in whom the unrulineſs of the Sulphur, are a little reſtrained, by the Salt, and Earthy dregs being ſtirred up with it, notwithſtanding which, all being leiſurely carried forth, break forth afterwards, with a greater ſlaughter.

When the Diſeaſe ſhall come to the ſtanding, either the buſineſs is done at one conflict, and from thence with a manifeſt declination, there is made a tranſlation to life, or death, or there are made frequent skirmiſhes, between Nature and the Diſeaſe, and critical motions are often attempted, before the victory is yielded to either party.

1. As to the firſt, If after the Bloud hath ſufficiently burned forth, with a good precurſion of ſigns and ſymptoms, and its burning hath remitted, the aduſt matter being equally brought under, and ſubtilated, ariſes from a full increaſe, to the motion of boiling up; and Nature being free from any impediment or depreſſion, is ſtrong with able ſtrength enough, for the decertation or ſtrife, the Feaveriſh matter, for the moſt part, is exterminated at one motion of its flowring or putting forth, and the Bloud being freed from its fellowſhip and infection, ſoon recovers its former vigour.

2. But if Nature is ſtirred up, to a critical motion, before the Bloud hath perfectly burnt forth, or that aduſt matter is prepared for excretion, altho', as to the reſt, things are in a moderate condition; yet from hence, but an imperfect Criſis follows, by which indeed, ſomething of the load or burthen, with which the Bloud is oppreſſed, is drawn away; notwithſtanding preſently another ſprings up afreſh, in its place, and then at ſet times, (perhaps, in four, or ſeven days ſpace) like the fits of intermitting Feavers, the critical motions are repeated, the ſecond, and perhaps the third time, before the ſtrife being ended, the matter openly inclines to this, or that party.

3. But when, with the preceding evil appearance, of ſigns and ſymptoms, the burning of the Bloud yet urging, the critical motion is provoked, without any coction of the Feaveriſh matter, ſometimes Nature is overthrown at the firſt conflict, nor doth ſhe recollect her ſelf, but yielding her powers overcome by the Diſeaſe, is precipitated into death. Nor is the buſineſs much better, when the Criſis is at firſt imperfect, and in vain, celebrated, without any eaſe to the ſick, and from thence, the next to this ſucceeds worſe, and then in another, and perhaps another conflict, the Diſeaſe prevails, until the ſtrength being wholly broken, and caſt down, there is a plain end of life.

Thus much concerning the ſtate and Criſis of the Diſeaſe, on whoſe good or improſperous ſucceſs, the event of the Diſeaſe depends; the declination of the Feaver, takes its period of this, of which we muſt ſpeak next.

4. Altho' the Declining of the Feaver, for the moſt part, is taken in the better part, that it denotes the condition of the ſick growing well of the Diſeaſe, in which the Bloud being almoſt freed from its Effervency, recovers leiſurely, ſtrength and ſpirits, that were loſt, and expels what extraneous thing is left remaining in its boſom; yet, in a genuine enough ſignification, it may be uſed for that ſtate, when from an ill Criſis, or in vain, the Bloud being depauperated, and infected with an extraneous and Feaveriſh mixture, ſtill declines for the worſe, until at length (like Wine changed into a lifeleſſneſs) being made wholly unable for circulation, and accenſion in the Heart, it calls on death. Therefore, in this place, the name of declination ſignifies the condition of ſick, and of the Diſeaſe, which follows the ſtanding, whether it tends to life, or to death; whether the Feaver, or life it ſelf of the ſick, at this time, declines.

As to the times of declination, it will be worth our labour to inquire, what the temper of the Bloud may be, and what turns of alterations it has undergone, as often as from a good, or bad Criſis, there has been made a progreſs of the Diſeaſe, towards Health, or Death. To wit, firſt, what the diſpoſition, or condition of the Bloud and Spirits may be, from a good Criſis, and with what alterations, its ſpoiled Liquor recovers its former vigor. Secondly, what their temper is, from an evil Criſis, and by what degrees it ſtill tends to worſe; and laſtly, how they are, when from a doubtful ſtate, and long weakneſs, the ſick hardly get up at length, and recover their health.

The vice, or depauperation, which the Bloud hath contracted from the Feaveriſh heat, conſiſts in this: The Spirit very much evaporates, and is loſt: the Sulphureous part is too much ſcorched, and is much waſted by the deflagration, and from its burning, the aduſt matter (as it were the *Caput Mortuum*) is left, with the Particles of which, the maſs of Bloud is aggravated, and debilitated; in the mean time, the Saline and Earthy parts, are too much exalted, even as is wont to come to paſs in Wine, or Beer, by the uſe of too much Ferment. The Bloud, by theſe ways being ſpoiled, evilly aſſimilates the proviſion of the Nutritious Juice, yea alſo, by reaſon of the roaſting of the Sulphur in the Heart, or defect of it, not rightly Fermenting, or inflamed, it untowardly diſpenſes the Vital Spirit, in the mean time, from the aduſt matter, and Salt too much exalted, it grows more fervent than it ſhould, and more waſts it ſelf.

1. From a good Criſis, the Spirit, tho' made weaker, yet gets the upper hand, wherefore, what is left of the Feaveriſh matter, it by degrees overcomes, and expels; and concocts, and aſſimilates (ſo what is brought be thin or ſlender) the Nutritious Juice: from thence, the maſs of Bloud is amended anew, with Spirit and Sulphur; and the Bloud which now being Salt and ſharp, did continually grow hot, acquires at length a Sweet and Balſamic Nature, and being quickned with a lively motion and heat, rightly performs the offices of life and ſenſe.

2. From a bad Criſis, the buſineſs is otherways, the Liquor of the Bloud (like Wine too much Fermented) degenerates, almoſt into a vappidneſs, or lifeleſneſs; its Spirit is greatly diminiſhed; the Reliques which remain, are intricated, and, as it were, overwhelmed, with the Particles of Aduſt Matter, from whence there is yet a continual growing hot remaining in the Bloud, yet without concoction, or aſſimilation, of the Alible Juice, or ſeparation of the profitable, from the unprofitable: The benign Sulphur, and the Food of the Vital flame, is much conſumed, ſo that the Bloud is leſs inkindled in the Heart, than it ought to be; in the mean time, from the Aduſt Recrements, and alſo the Salt, and Earth being too much carried forth, it perpetually burns in the Veſſels, with thirſt and heat. And becauſe it is dayly depauperated, the Spirit and benign Sulphur being waſted, and more infected, with the Salt, and Earthy dregs being too much exalted, its Liquor in a ſhort time becomes taſtleſs, and is made unfit for circulation, and for the inkindling in the Heart, for the ſuſtaining the Vital fire: wherefore there is a neceſſity that life be loſt, even as the flame of a Lamp is extinguiſhed, when inſtead of the waſted Oil, a Salt and Muddy Liquor only ſupplies it.

3. From

3. From an imperfect and doubtful Criſis, when the ſick being weakned by a long imbecility, become not well, but of a long time, the buſineſs is after this manner; The Spirituous and Sulphureous parts of the blood are very much conſumed by the ſlow deflagration; the remaining Liquor, being not purged from the aduſt recrements and feculencies, is rendred very impure; but when there is yet remaining ſomthing of Oil for the Vital Lamp, nor Spirits are altogether wanting, for the ſubduing the Feaveriſh matter, the blood is ſtill circulated, and (though but ſmally) is enkindled in the Heart; yea, and by little and little the Spirits recollect themſelves, ſet upon the matter remaining of the Feaver, and what they are able, begin to overcome it: then by a pertinacious aſſiduity of coction, like a flame, wavering and half extinct, among green wood, at length riſe up victorious, and reſtore anew, both with heat and motion, leiſurely renewed, a quick and lively Fermentation, in the Heart.

So much in general of the Feaver called Putrid: it remains, before we deſcend to the kinds, and particular Caſes of it, that I recount the ſymptoms and ſigns chiefly notable, in the courſe of this Feaver, and ſubjoin the Reaſons and Cauſes of them, and their manner of being done.

Chap. X.

Of the Symptoms and Signs chiefly to be noted in a Putrid Feaver.

THE Symptoms, coming upon a Putrid Feaver, although they argue the œconomy of the whole Body, to be for the moſt part depraved, and the diſpoſition and Functions of ſome part, or Member hurt; yet, the Accidents, which a Phyſician ought chiefly to conſider, about the Diagnoſis of this Diſeaſe, and its Prognoſis to be rightly inſtituted, may be referred to three claſſes or common places; to wit, they have reſpect to the Viſcera of Concoction, *viz.* the Ventricle, and Inteſtines, with their Appendixes: Or ſecondly, to the Humors, flowing in the Veſſels, *viz.* the blood in the Arteries and Veins, and the thin Liquor in the Nervous parts, together with the chief Springs of either, *viz.* the Heart, and Brain; or laſtly, theſe Symptoms reſpect the habit of the Body, with the various conſtitution of the pores, and the extenſion or emarceration of the ſolid parts. They, who would exactly obſerve the courſe of this Diſeaſe, and would fitly draw out Curatory intentions, may take notice of theſe three heads of Symptoms, and carefully conſider what alterations may happen in theſe; as it were diſtinct Regions, according to the different times of the Feaver.

1. Troubles and Diſorders, ſuch as Nauſeouſneſs, Vomiting, want of Appetite, Indigeſtion, a Looſeneſs, a Scurfineſs of the Mouth and Tongue, a bitter Savour, are wont to infeſt about the Ventricle, and firſt Paſſages, in the whole courſe of this Feaver. Theſe, for the moſt part, are attributed to the humors, firſt heaped together in the Stomach, and there putrefying: But beſides, that the recrements of the Chyle, being throughly roaſted, by too much heat, degenerate into an hurtful matter, very often theſe kind of Accidents happen, for that the Purgings, and the Filth of the Blood and Nervous Juice, while they grow hot, are carried inward, and being depoſited in the membranes of the Viſcera, provoke Convulſions, and alſo make a filthy heap of vicious and very infeſtous humor. I have often obſerved, that about the beginning of the Feaver, the blood growing hot, laid aſide its recrements even inwardly, with a benefit to the ſick, where, although great moleſtations did ariſe about the firſt paſſages, yet the burning was therefore more mild, the Pulſe moderate, and the Urine laudable, and theſe being after this manner in a Feaver, quickly grew well, with a ſlender Diet, and the uſe of gentle evacuations. But if in this caſe I ſhould adminiſter a vehement Cathartic, for the extirpating the humors, that natural purging of the Blood being hindred, preſently the Feaver became ſtrong, with a red Urine, and troubled, a deep Pulſe, Watchings, and other horrid Symptoms; alſo, oftentimes after the ſtate of the Diſeaſe, by this interior kind of Luſtration or Purging, the aduſt matter, and excrementitious, is ſeparated from the Blood. Hence ſometimes a Lask, ſometimes a ſcurfie covering of the Mouth and Throat, follow: Wherefore, there is need of caution, about the Accidents which happen in the firſt paſſages, leſt that whilſt we oppoſe them, we ſhould pervert the motion of Nature; and leſt whilſt we fortifie theſe parts againſt the courſe of the Morbific matter, we untowardly keep the ſame ſhut up in the Maſs of Blood.

The Symptom chiefly to be conſidered, about the bloody Maſs, are, an heat diffuſed through the whole, a burning of the Præcordia, Thirſt, a Diſorder of the Pulſe, a red Urine, a ſpontaneous weariſomneſs, a loſs of all ſtrength, out of which rightly conſidered, theſe things following may be known, *viz.* what the manner of the heat is, or with what tenor the burning blood

flames forth; what time of remiſſion, or of encreaſe its Efferveſcency obſerves in the deflagration; whether it retains its Craſis or Mixture whole; for the burning of it, and circulation of it enkindled, what ſtrength of the Heart will ſuffice, and what ſpace the Veſſels may require; ſo long as the blood burns, what plenty of aduſt recrements it may heap up, by what means it may overcome, ſeparate, or at leaſt endeavour to ſeparate the ſame, and laſtly, what way of a Criſis it endeavors, and with what ſucceſs.

The Accidents which have a reſpect to the thin Liquor, with the Brain, and nervous Appendix, are diſorders concerning Sleep and waking, a debility of the whole Body, a Trembling, Shivering, Pains, Convulſive Motions, Cramps of the Viſcera, Stupefaction, Phrenſie; and the obſervation of which ſuggeſts what the temper and conſtitution of that thin Liquor may be; by what means it waters, and influtes the nervous parts, and performs its Circuits through them; how the Animal Spirits execute the functions of the Viſcera; what the ſtate of the Brain may be, whether it remain free from the incurſion of the Feaveriſh matter, or whether it be not in danger of being overwhelmed, by reaſon of its Critical Metaſtaſis or Tranſlation.

Concerning the habit of the Body, may be obſerved, what may be the reaſon of ſweating, and the manner of it; whether only by vaporous *Effluvia*, or by Sweat, or alſo by little wealks; whether the Fleſh falls away on the ſudden from its wonted bulk; or whether it retains it ſelf a long while; what the colour of the Face is, and the vigor or habit of the Eyes? From theſe well laid together, the courſe of the Feaver may be beſt of all meaſured; at what time it will come to its height or ſtanding; whether Nature will prevail over the Diſeaſe or not; with what manner of ſeparation, and with what ſucceſs ſhe will endeavor the expulſion of the Feaveriſh matter; alſo by theſe ſigns may be learned, by what degrees the blood growing hot, and often congealed, doth tend towards Putrefaction or Corruption; whether it does any thing concoct the alible Juice poured to it; or whether or not it preſently caſts forth of doors all its proviſion by Sweat, as often happens in the declination of this Diſeaſe.

By theſe Symptoms and Signs, a yet more plentiful Indication may be had, if firſt it be known upon what Cauſes the ſeveral Species of them depend, and, by what proviſion they are wont to be raiſed up in our Body: wherefore I have thought it worth our labour to recount particularly the chief of theſe; and to explicate the Reaſons of them, and their ways of working.

But the Symptoms chiefly to be obſerved in a putrid Synochus, or continual fervor without intermiſſions, are, an heat in the whole Body, a ſpontaneous Wearineſs, a burning of the Præcordia, intolerable Thirſt, an Ardor and Scurfineſs of the Tongue, or Jaws, a Pain of the Head and Loins, pertinacious Watchings, Phrenſie, convulſive Motions, a Syncope, Heart-burning, Vomiting, Nauſeouſneſs, a want of Appetite, a Looſneſs, a Flux, with which, not all at once, now with theſe, now with thoſe, this Diſeaſe is wont to be beſet.

1. Heat, which is felt ſharp and biting, in the whole Body, depends upon the too great efferveſcency of the Blood, and the accenſion of it in the Heart; for the Sulphureous or Oily part of the blood being exalted, and taking an heat, is enkindled in the Heart, in a double proportion, more than it was wont; wherefore, it copiouſly diffuſes, by its deflagration, *Effluvia* of heat through the whole Body. When the Sulphur is leſs diſſolved, and enkindled in the Heart, as in the Green Sickneſs, or the white Dropſical Diſeaſe, *&c.* Heat is wanting in the whole; but in a Feaver, when the Sulphur too much burns forth, Heat ſuperabounds. For heat depends not only upon the actual inflammation of the Sulphur, or the firing of it, but an intenſe heat is excited without fire, in many mixtures, where the Particles of Sulphur are diſſolved by corroſion, or are more thickly heaped together for want of ventilation; wherefore, when Iron is corroded by an acid mineral Spirit, or when Spirit of Nitre is poured on the Butter of Antimony, a mighty heat with a Fume is produced; in like manner when Dung, or Hay laid up wet, are kept from ventilation, grow highly hot; it is the ſame reaſon, why the Blood burns above meaſure in Feavers, to wit, the particles of the Sulphur, being too much exalted, and made hot, are more thickly heaped together in the Veſſels, and are more diſſolved, and as it were enkindled by the ferment of the Heart; wherefore, they every way diffuſe heat, being looſned in the bond of the mixture, and every where ſtretched forth or expanſed.

2. A ſpontaneous Wearineſs or Laſſitude is felt in the whole Body; to wit, by reaſon of the Veſſels being diſtented with the boiling blood, alſo the muſculous fleſh is very much ſtuffed with blood, and a copious breath, that it is made leſs fit for motion, as they who are ſick of an Anaſarca, have their Limbs very unwieldy by reaſon of the abundance of ſerous humor; beſides, in Feavers, by reaſon of the inflammation of the blood, the Juice, which is ſent for a ſupply to the nervous ſtock, departs from its due temper, that it becomes little fit for the actuating the Body.

3. The burning of the Præcordia is made, by reaſon of the blood being more copiouſly enkindled in the Chimny of the Heart, which from thence boils forth into the Lungs, with great ardency; wherefore by how much the nearer this Region is to that fire-place of Heat, it is pierced therefore with the greater burning.

4. An

4. An almoſt unquenchable Thirſt is cauſed, both from the glowing heat in the Præcordia, alſo by reaſon of the ſharp and hot particles of the Feaveriſh Matter, affixed to the Ventricle, in the circulating of the Blood; which indeed deſire to be waſhed, even as ſalted and ſpiced Meats, being plentifully eaten, or alſo ſtrong, or ſowr things, rolled in the Mouth or Throat; for this kind of Diſtemper calls for a more free ſwallowing down of Drink, as a Member too much heated, the pouring on of cold water.

5. The Ardor and Scurfineſs of the Tongue and Jaws, as alſo oftentimes an accretion of a certain white, or yellow, or black filth, happen without doubt, becauſe of the Heat and Soot exhaled from the Ventricle and Lungs, burning with heat: but the Tongue grows white, as often as that humidity (with which it is naturally much imbued)is dried up, and parched, and ſo the exterior skin of the Tongue,is as it were roſted,by the burning heat, from hence alſo it becomes ſcurfie; which is alſo ſeen in healthful people, when it happens that the Tongue is ſcorched by Broth, or any other very hot Suppings; in like manner, as when the Tongues of Animals are boiled, for the uſe of the Table, their Skin becomes white and ſharp, or rugged. For whether the Spittle is drawn from the maxillary Glandula's (as the Doctrine of the moſt ingenious *Wharton* hath firſt made known) or any other humor from the Glandula's of the Jaws, or elſewhere; yet becauſe, by reaſon of the heat and drineſs, it grows too thick, and becomes clammy, alſo then the outward skin of the Tongue grows nevertheleſs white; but alſo it is covered with a certain filthy Glew, to wit, becauſe that humor, by reaſon of its thickneſs, may ſmear the Tongue, but cannot wet or moiſten it; but if it happens, that the Tongue is inwardly ſuffuſed with a bilous humor, or outwardly tinged (as comes to paſs by the uſe of Choler-abounding Vomits) then its hairy Nap being ſpongy, imbibing the yellow poyſon, exhibits alſo the like Colour, If that laſtly, the heat be ſo ſtrong, that it burns the Blood, and enkindles a fire, more ardent than uſual, it follows, that from the fire-place of the Heart, the breathing places through the Lungs, ſcarcely ſufficing for the ventilating ſo great fire, ſoot or ſmoak is raiſed up, which being ſmitten to the furnace of the Palat, ſtrikes againſt the Tongue, as it were in a Reverberatory, and infects it with Blackneſs. But this ſame kind of Blackneſs (and as other filthineſſes of the Tongue) is moſt conſpicuous in its middle parts, becauſe the more exterior compaſs is cleanſed by its frequent rubbing againſt the Gums and Palat.

6. Sometimes it happens in Feavers, and eſpecially about their declinations, that the Tongue, Palat, Gums, yea the Cavity of the whole Mouth and Throat, are covered over with a certain viſcous matter, as it were a whitiſh Cruſt; which being often wiped off, preſently new ſprings again; and unleſs by rubbing diligently, and waſhing the Mouth, this cruſty matter be frequently wiped away, the ſick are in hazard of being choaked. This kind of Diſtemper is moſt often excited in Children newly born; for they are wont, for the moſt part, within fourteen days with an external growing hot, to be ſprinkled through the whole skin, with broad and red ſpots; if that this ſuffuſion of redneſs do not freely break forth, or vaniſhes away ſooner than it ought, for the moſt part, this whitiſh Cruſt follows, in the parts of the mouth. This Symptom, when it troubles Infants after this manner, is wont to be aſcribed to the fault of the Milk, to wit, that being too ſharp, it induces the ulcerous Diſtemper of the Mouth. In thoſe ſick with Feavers, it is commonly attributed to thick Vapors and ſooty, elevated from the Ventricle; But to me it ſeems moſt likely, that in either, this Diſtemper ariſes from the impurities of the whole Bloud (and perhaps in ſome meaſure of the Nervous Juice) depoſited about theſe parts: for, as often as in the maſs of either humor, any extraneous thing intimately mixed, is contained, that it is not to be diſperſed by Sweat, nor eaſily ſent away by Urine, that moſt often is fixed with the ſerous filth about the Mouth; from whence Catarrhs, Tumors, and troubleſom Spittings are cauſed: For when for the chewing of the meats, the Salival humor in this place ought to be plentifully ſuffuſed, Nature very often endeavours to ſend forth of doors what is ſuperfluous, or otherwiſe troubleſome, by theſe uſual ways of Excretion. Hence from Mercury being taken, when both the Bloud, and nervous Juice are abundantly ſtuffed, with its moſt ſmally divided Particles, and endeavour to thruſt them forth, being involved with Serum becauſe they are not able to exterminate thoſe Mercurial little Bodies, being intimately confuſed, neither by Sweat, Urine, or by any other ways, what is remaining, they endeavour to expel through the Arteries and other Paſſages, which ſupply the Mouth with Spittle, the ſame being involved with the ſerous Latex.

Alſo in like manner, in Feavers, when from a long deflagration of the Bloud, the aduſt matter is very much heaped together, of which no ſmall part remaining, after the Criſis, is yet confounded with the Bloud, and Nervous Juice, being fixed either to the Brain, or to ſome other place, from them it is at length ſupped up again, 'tis moſt probable, that this matter is throughly roaſted, by a long Concoction, and ſo becomes almoſt like Glew, thick; wherefore being not able to be diſperſed, neither by Spittle, or inſenſible Tranſpiration, nor to be ſeparated by the Urinary Paſſages, but at length leiſurely runs out by the little Arteries, and other Paſſages of the Spittle, lying open into the Palat, as the moſt uſual way of excretion, and forthwith by reaſon of its thickneſs, grows into that Glewineſs. The ſame reaſon holds

in

in Infants, whose blood being made impure, by filths contracted in the Womb, presently it endeavors to purifie it self, by that exterior putting forth, which if it do not rightly succeed, by reason of the thickness of the matter, immediately the viscous impurities are exterminated by this way, as the more open. I have known some, in the declination of a Feaver, to whom, not only this kind of Crust of gummy matter has happened in the parts of the mouth, but a copious salivation, as if they had taken Mercury, with a stinking of the breath, also a swelling of the Tongue and Gums, hath been raised up for many days.

7. The pain of the Head, in Feavers is excited, because the Meninges of the Brain, being pulled or hauled with Vapors, and with a sharp Blood, and hot, for the Blood being impetuously moved, by reason of the direction of the great Artery, is carried in a greater plenty to the Head, than to the lower parts; because the passage from the bosom of the Heart to the Head, is straight, from the same, to the inferior members, oblique, and as it were reflected; wherefore, as the membranes are very sensible, and that there the Blood is stopped, and reverberated, in its rapid course, it is no wonder, if cruel Head-aches are excited in Feavers. Besides, this impetuous flowing of the Blood, wherewith (as it were by a certain Ramming) the membranes of the Head being distended, ake grievously; also sometime, Head-aches arise, by reason of the Nervous Juice (which is supplied from the burning Blood) being too sharp and pricking; wherefore, when the membranes, and nervous parts are watered with the same they being pulled by its acrimony, are moved into Pains and Convulsions.

8. In like manner also, the other Distempers of the Head, as Watchings, Delirium, Phrensie, Convulsion, *&c.* arise, sometimes from the Blood being in a rage, and so stirring up inordinate motions in the Brain, and sometimes also from the nervous Juice being depraved, and therefore made improportionate, to the regiment of the Animal Spirits: But most often, these kind of Symptoms are frequent in Feavers, by reason of the translation of the Feaverish matter from the bosom of the Blood, into these parts. For the Blood, being full of the adust Recrements, remaining after the deflagration, endeavours (like the flowring of new Wine) to subdue, and exclude them from its company, by every manner of way; which, a Flux being arisen, when it cannot expel by Sweat, Urine, or Bleeding, it oftentimes transfers to the substance of the Brain, and there fixes them; and from hence chiefly, the aforesaid Distempers, when they are fixed, and firmly rooted, draw their Original, whenas the lighter, and that are easily moved, often proceed from the afore-recited Causes.

9. Convulsive Motions happen in Feavers, for divers causes; sometimes, because of the matter being heaped together in the first passages, which there hales the membranous parts, with its notable pravity, and then, by the consent of the nervous stock, the Convulsion is presently communicated to the beginning of the Nerves, in the Brain, and by that means draws aside now these, and now those parts: by which means, Worms abounding in the Viscera, sharp Humors being stirred, and strong Medecines, induce Convulsions: Or secondly, when the Feaver is a partaker of some malignity, so in the Small Pox, Measles, or the Plague, frequently Convulsions happen; to wit, because the Blood is altered from its benign and natural temper, into a destroying and venomous, by which the Nerves, and their beginnings are peirced, and forced into Convulsions. Also, oftentimes without the suspition of malignity, in a putrid Feaver, Convulsive motions are induced by reason of the translation of the Feaverish matter to the Brain, as was but now intimated: so I have often observed, when the Disease is not presently cured with the Crisis, the sick lie by it with a tedious sickness, and are made obnoxious to Tremblings and Convulsive motions. Thirdly, and lastly, for the most part in every Feaver, which terminates in Death, Convulsive motions are the sad fore-runners of it; which I think to happen, not only from the malignity of the Matter, with which the nervous stock is pulled and pierced, but because the Spirits, very much exhausted and debilitated, do not sufficiently blow up, and distend the Bodies of the Nerves; wherefore, being released from their wonted extension, and tonick motion, they are however by a more weak endeavor of the Spirits agitated into a disordered motion.

10. A Syncope or Swooning, is wont to be raised up several ways in Feavers; but chiefly for these three causes, to wit, either from the mouth of the Ventricle being distempered, which part as it is interwoven with a manifold texture of Nerves, is very sensible; and because from the same branch of the sixth part, little shoots of Nerves are equally derived to the Heart, and to the Ventricle, if the Orifice of the Ventricle, so implanted with Nerves, be distempered with any great trouble, it is also communicated to the Heart, and either the motion is stopped in it, or at least an inordinate one is excited, whereby the equal Flux of the Spirits and the Blood is interrupted for a time. I knew one in an acute Feaver, taken with a frequent swooning, which distemper wholly ceased, after he had cast forth by Vomit a long smooth Worm. Secondly, a Syncope also is sometimes induced, because the invenomed matter is circulated with the Blood, which suddenly fixes and extinguishes the vital Spirits, and congeals the Blood it self, that it is apt to stagnate in the Heart, as usually happens in the Pest, Small Pox, *&c.* of which we shall speak particularly hereafter. Thirdly, A Syncope is wont to happen,

happen, by reaſon of the more rare texture of the Spirits, which as they are very tender and ſubtil, are eaſily unbent, by any immoderate motion or pain: ſo I have known ſome, who being quiet in bed, have found themſelves well enough, but being removed from one place to another, preſently have ſwooned away.

11. The pain of the Heart happens in Feavers, when the Ventricle, and eſpecially its Orifices, by reaſon of the manifold inſertions of Nerves, being very ſenſible, are beſet with a ſharp and bitteriſh humor, or elſe with an acid, and corroſive; for hence a pain and trouble ariſes from the acrimony of the humor, after the ſame manner, as when the ſphincter of the fundament is afflicted, in Choleric dejections, with pain and moleſtation.

12. By reaſon of the ſame Cauſe, Vomiting, and Nauſeouſneſs, are wont to be excited; to wit, by the Ventricles being beſet, and irritated to a Convulſion, from an extraneous matter, and not akin to it ſelf: Such an excrementitious matter, may be gathered together in the Ventricle, by three ways; for either the Aliments, partly by reaſon of a want of an Acid Ferment, by which they ſhould be rightly Cooked, and partly by reaſon of the burning heat of the Ventricle, are roaſted into ſuch a Corruption; or, Secondly, this kind of matter, is laid up in the Ventricle, from the Arteries, terminating in its Cavity, as uſes to happen in the Small Pox, the Plague, and malignant Feavers; or, Thirdly, meer Choler, being preſſed forth from the Choleduct Veſſels, into the empty Inteſtine, by reaſon of an inverſe motion, and as it were Convulſive, of that Inteſtine, it is poured into the Ventricle, want of Appetite, alſo happens, by reaſon of the Ventricles abounding with vitious Juices, and becauſe the Acid Ferment, is wholly perverted, by the ſcorching heat. Theſe kind of Diſtempers of the Venticle, and Viſcera, ſometimes ariſe from an excrementitious matter, (to wit, alimentous, degenerated in the concoction) heaped together, a long while before the Feaver, in the firſt paſſages, which not ſeldom becomes, the occaſional cauſe, of the Feaver it ſelf: but ſometimes, nauſeouſneſs, want of Appetite, Vomiting, pain of the Heart, *&c.* are the immediate products of the Feaver; for when the day before the ſickneſs, thoſe diſtempered, have been well enough in the Stomack, as ſoon as the immoderate heat of the Bloud was induced, whilſt it boiled up above meaſure, both the *Effluvia*, and the Recrements, being wonted to be evaporated outwardly, alſo the bilous humor, flowing out of the Choleduct Veſſels, are poured into the Ventricle; by which, its Criſis is overthrown; alſo the Reliques of the Chyle, and other Contents in the Viſcera, are egregiouſly depraved; from whence, the aforeſaid Diſtempers draw their Original.

14. No leſs frequent a Symptom in Feavers, is a Diarrhea, or Flux of the Belly, which ſometime happens about the beginning of the Diſeaſe, and ariſes (for the moſt part) either from the Bile, flowing forth of the Choleduct Veſſels, into the *Duodenum*; or from the Recrements of the Bloud, and Nervous Juice, poured forth from the Arteries, and the paſſage of the Pancreas, into the Inteſtines. All the aforeſaid humors, (but eſpecially the Choleric) when they are ſupplied in abundance, often Ferment with the maſs remaining of the Chyme, that the ſame ſwelling up with a ſpumous rarefaction, irritates the Inteſtines, and provokes to the motion of excretion: ſometimes alſo, about the ſtanding of the Diſeaſe, and in the declination of it, a Lask is excited; and ſo, either Nature being Conquereſs, the more thick purgings of the Bloud, are this way critically ſifted forth; or being overcome, the Flux of the Belly, is the effect, and ſign, of the Viſcera wholly loſing their ſtrength, and firm tenour. It ſometimes happens in a Feaver, that the Belly is always bound, that it is not at all looſned, but by Phyſick, and tho' the ſick take nothing but liquid things, for many days, the ſtools are ſtill of a ſolid conſiſtence, and hard, this ſeems for the moſt part to be done, when the Bloud growing ſharply and exceeding hot, like fire, conſumes the humidities, wherever they flow, and draws to it ſelf, out of the Bowels, the watery matter, by a Copious emiſſion of vapours, and preſently makes it to be evaporated outwardly: wherefore, the thicker part, being left in the Inteſtines, is made firm, from the ſcorching heat, as it were a *Caput Mortuum*, remaining after diſtillation.

A Dyſentery is a Diſtemper, ſo frequent in continual Feavers, that ſome years it becomes Epidemical, and not more mild than the Plague, kills many: The cauſe of it is wont to be, not any humor produced within the Viſcera, that corrodes the Inteſtines with its Acrimony, (as ſome affirm) but a certain Infection impreſſed on the Bloud, and ſo intimately confuſed with it, that, under the form of a vapour, or a ſincere humor, it cannot be pulled away from the Bloud: wherefore, the thruſting forwards, towards the Inteſtines, unlocks the little mouths of the Arteries, and makes there little Ulcers, and exudations or flowings forth of the Bloud, like as when from the Feaveriſh Bloud, Puſtles and Inflamations break forth outwardly, with a flowring towards the skin: But it is moſt likely, theſe dyſenteric diſtempers, which accompany Malignant or Epidemical Feavers, ariſe from a certain coagulation of the Bloud, as ſhall be more fully declared hereafter.

And

And here alſo, among the ſymptoms of Feavers, might be recited, what are wont to appear outwardly, in the ſuperficies of the Body, as are Spots, Whelks, Buboes, Carbuncles, *&c.* but becauſe theſe belong after an eſpecial manner to a Malignant Feaver, therefore we will forbear in this place, from the conſideration of them, until we ſhall ſpeak of the Plague, Small Pox, the Peſtilential, and Malignant Feaver.

The Pulſe and Urine ſhall conclude here the troop of ſymptoms and ſigns in a Putrid Feaver, which are much heeded, for the finding out, both the ſtate and the ſtrength of the ſick: For, as there are two things, by which our life is propped, *viz.* Heat inkindled in the Heart, and concoction to be made in the Viſcera, and Veſſels, becauſe the Pulſe and Urine, beſt ſhow the alterations in either, induced in a Feaver, therefore from hence, a moſt certain judgment is taken of this Diſeaſe, about to end, in Death or Health. I think it is not needful, to ſpeak of theſe at large, or to recount the ſeveral cauſes and differences of either: It will ſuffice for me to note here, the chiefeſt things of them, and what are worthy of conſideration in the courſe of Feavers. And firſt of all the Pulſe is conſulted, as it were a Thermometer or Weather-Glaſs, conſtituted by Nature, that from thence, the heat inkindled, in a Feaver might be meted; which if it ſhould be more ſtrong, ſtirs up a great ebullition or boiling up of the Bloud, the Artery beats more ſtrongly and quicker, ſo long as the Spirits are in ſtrength; then they being a little exhauſted, the more ſtrong Pulſe is remitted; which however is compenſated with ſwiftneſs, and is made quick, and ſmall. If the Feaver be gentler, and is troubled with a leſſer burning, the Pulſe alſo declines leſs, from its Natural condition, and the moderation of this, in the whole courſe of the Diſeaſe, denotes the truces of Nature. Neither doth the Pulſe only, betray the forces of the Feaver, as of an Enemy, but ſhews alſo plainly the ſtrength of Nature, and her ability of reſiſting. So long as the Pulſe is laudable, the matter goes well, and it ſhews good hopes; but from the evil ſtate of this, a bad omen is ſhewn, and a deſpair of Health. So without a frequent, and diligent examination of the Pulſe, a Phyſician cannot make a right Judgment or Prognoſtication, or ſafely preſcribe Phyſick.

1. As to the firſt thing, it ought to be known (as much as may be) what every ones Pulſe is, according to its Natural Conſtitution; for it is in theſe ſtronger, in thoſe weaker: then it is to be conſidered, in every moment of the Feavers, by what degrees it is diſtant from its Natural ſtate: for now it is ſometimes more vehement, and argues the Feaver to grow ſtronger; now it is depreſſed, below its wont, and denotes the Spirits and Strength dejected.

Thoſe whoſe Pulſe in Health beats weakly and languiſhing, when taken with a Feaver, if they have a ſmall and weak Pulſe, it is not ſo evil a ſign, that we ſhould preſently deſpair of their Health: In whom the Pulſe is by Nature ſtrong and vehement, if after the Criſis of the Diſeaſe, it hath ſcarce a moderate vigour, tho' it be not wholly weak, it argues the condition of the ſick to be ſuſpected, and not ſafe.

If from the beginning of the Feaver, before the Bloud has flamed out, or if a Criſis being made, when part of the burthen is drawn away, or at another time, without an evident cauſe, the Pulſe becomes weak, it portends evilly: but if after long watchings, or great evacuations, the Pulſe is made a little weaker, Health is not therefore to be deſpaired of, becauſe the ſtrength caſt down by theſe means, or overwhelmed, may be reſtored, and the Spirits renewed.

When the Pulſe is ſuddenly altered for the worſe, tho' the ſick ſeem to be better, as to the reſt of the ſymptoms, you may foreſpeak the ſad prognoſtication of Death; and ſo contrariwiſe, altho' moſt horrid ſymptoms urge, and yet the Pulſe is laudable, Health may be yet hoped for. If in a ſtrong man, that hath a Feaver, the Pulſe is very ſmall, and creepingly, or becomes like the motion of Ants, death is at hand.

2. In the exhibiting of Medicines, cautions and rules of no ſmall moment are taken; Purging and Vomiting are forbid, by the pulſe being too quick and violent; alſo by being low and depreſſed; becauſe, whilſt the Bloud is too fervent, evacuation helps little, becauſe both what is hurtful is not ſeparated, alſo for that by the perturbation, the ſtrength or ſpirits, are more debilitated. But when the ſpirits are broken, and ſtrength caſt down, Medicines caſt them more down, and ſometimes wholly overthrows them. Wherefore, when a Phyſician thinks of evacuation, upwards or downwards, he firſt examines the pulſe, and goes about this work only, when Nature is ſtrong and quiet; that ſhe may at once be at leiſure, for the operation of the Medicine, and may have ſufficient ſtrength.

Nor is there leſs need of circumſpection, in ſweating Medicines and Cordials: which, if adminiſtred in the Feaveriſh fit, do too much ſtrengthen, the former violent motion of the Heart, and oftentimes break its ſtrength; alſo, when the Pulſe is very languid, if hot and ſtrong Cordials are adminiſtred, (as when a ſmall flame is troubled with a more ſtrong blaſt of wind) life is eaſily extinguiſhed; wherefore, 'tis a vulgar obſervation, that Cordials often accelerate death, for that by too much troubling the Bloud, they ſooner beat down ſtrength.

There is yet the moſt need of the caution, and direction of the Pulſe, in exhibiting Narcoticks; for theſe, (becauſe they perform their work by extinguiſhing, and fixing the too fierce vital ſpirits) if uſed in a weak or inconſtant Pulſe, either by diminiſhing the vital ſpirits, render them

them wholly inſufficient for the Diſeaſe, or by ſuffocating them too much, cauſe a perpetual ſleep: wherefore, in a languid, unequal, or formicating, or creeping Pulſe, Opiats are to be ſhunned, more than a mad Dog or Snake.

An unequal and intermitting Pulſe has a moſt evil Report from the Writings of Phyſitians; yet, although of an ill note, does not ſo certainly portend Death, as a Weak Pulſe; for I have known many to have recovered, though, by thoſe kind of ſigns condemned to the grave; becauſe the inordination of the Spirits and the Blood, may be more certainly and eaſily compoſed, or allayed, than their dejection reſtored.

2. The Inſpection of Urines in Feavers, before all other Diſeaſes whatſoever, hath more of certainty, and is of greateſt uſe, for from hence, the conditions of the ſick, and of the Diſeaſe are beſt known, and the Medical intentions, concerning what is to be done, are better directed; what Obſervations and Rules concerning this thing, are vulgarly ſet forth, are ſo many, that it would be almoſt an infinite labour and tedioufneſs, to recount them all: it will be ſufficient here to note the chief of them.

Concerning the Urines of perſons in Feavers, there are chiefly to be conſidered, the Colour, Conſiſtency, Contents, and Subſidency or Setling. The Colour of the Urine ſhews the meaſure or exceſs of heat in the Blood; which, as it is increaſed, and becomes more remiſs, the Urine alſo is more or leſs red; the cauſe of which is, the ebullition of the Blood, or the Efferveſcency induced from the Feaver, to the Blood; by reaſon of which, the particles of Salt and Sulphur, implanted in the Blood, Humors, and ſolid Parts, are more diſſolved, and incocted with the Serum, and impart to it a redneſs; even as, when Salt of Tartar, and common Sulphur being mixed one with another, and boiled in water, impart a deep red colour to the Liquor.

The Urines of ſome are highly red, when they are but a little or lightly Feaveriſh: and on the contrary, the Urines of others, labouring with a Feaveriſh Burning, are leſs coloured. Who abound with lively heat, and a very hot Blood, or are obnoxious to the Scurvy, Phthiſis, or Hypochondriack Diſtemper, when by taking Cold, Condenſation, Surfeit, or Drinking of Wine, they are troubled by any little Feaver, they render a Urine ſtrongly red; for that the Particles of Salt and Sulphur remain exalted in their Blood, and before half looſned; wherefore there is a neceſſity, that the Feaver urging, they are more boiled in the Serum; on the contrary, they who are endued with a cold temper, with a faint and weak Pulſe, being taken with a Feaver, with a greater efferveſcency of the Blood, render their Urine leſs coloured.

The Conſiſtency, Contents, and Subſidency of Urines, being put, as it were, upon the ſame Thred, depend all of them, on the aduſt and recrementitious matter, which is remaining in the Blood, after the Feaveriſh deflagration: if there ſhall be plenty of this, the conſiſtency of the Urine becomes ſomewhat thicker, and after it has ſtood, it is troubled by the Cold; but if there be a leſſer quantity of this, or otherwiſe derived than to the Reins (to wit, by Sweat, or is called away by a critical Tranſlation, to this or that part) the Conſiſtency is made thinner, and the Liquor remains clear. Alſo the Particles of this Matter do enlarge the Contents of the Urine, which ſhew themſelves diverſly, according as the nutricious Juice, is now ſomewhat cooked, and aſſimilated by the Blood, now altogether perverted, and carried into a putrefaction, ſome ſigns of Concoction and Aſſimilation ſhew themſelves in the Urines of Feaveriſh perſons, now a laudable Hypoſtaſis, now ſome Marks and Rudiments of the ſame. A want of Hypoſtaſis, and the Confuſion, and Perturbation of the Urine, denote the Concoction vitiated. But as this Matter is more or leſs roaſted in the Blood, the Contents are now of a pale, now of a red Colour, like Oker. By reaſon that the recrements, confounded with the Blood, either the Spirit being ſtrong, begin to be overcome, and ſeparated, or the ſame being depreſſed too much, they are leſs able to be ſeparated: alſo the Contents of the Urine are wont to be more or leſs, ſooner or ſlower ſeparated from the reſt of the Liquor, and to ſink down towards the bottom.

As to the Prognoſticks, to be taken from the Urine, we may take notice, that the Colour of the Urine being ſomewhat more remiſs, the Conſiſtency mean, the Contents few, the Subſiding free, or eaſily collected into a Cloud, portend good: on the contrary, a deep red, a thick and troubled Conſiſtency, thick and cloudy Contents, which ſlowly or ſcarce at all ſink to the bottom, denote a very great Heat, plenty of aduſt Matter, and its being brought under, and ſecretion, difficult, or fruſtrated.

As to the Medicinal Directions, the buſineſs depends on this, that we attend, by the frequent inſpection of the Urine, the motion of Nature, and be helpful to the ſame; neither is it to be moved by Purge or Sweat, but when a certain Hypoſtaſis of the Urine ſhews ſigns of Concoction and Separation. I thought it needleſs to ſay any more here concerning this Matter, becauſe thoſe things are more largely handled elſewhere, in a proper place, which belongs to Urines.

CHAP. XI.

Of the Kinds, and Cure of a Putrid Synochus, or Continual Feaver.

AND thus much for a Putrid Synochus in general, in which is deſcribed its formal reaſon, according to the Accidents and Symptoms which are commonly obſerved in its Figure; there are beſides (I ſhall not ſay Species, but) but ſome Varieties or Irregularities of this Diſeaſe, in which this Feaver ſometimes declines from this common Rule, and by reaſon of ſome accidental Diſtempers, gets new Names and Diſtinctions.

In the firſt place therefore, a Putrid Synochus is wont to be divided into Symptomatick, and Eſſential; It is called Symptomatick, which draws its beginning from ſome other Diſtemper, or Diſeaſe before excited in the Body, ſo that the Feaver is only a Symptom, coming upon that other Diſeaſe: of which ſort is accounted, what depends upon the Squinancy, Pluriſie, the Inflammation, or Impoſthume of the Lungs, or any Impoſthume from a wound, or Ulcer in a principal part, or its Neighborhood, of which we think a little otherwiſe, *viz.* That truly no putrid Feaver is meerly Symptomatical; perhaps it may ariſe occaſionally, from ſome other Diſtemper; but it is founded immediatly, in the Sulphureous part of the Blood being made too hot, and as it were enkindled: for without a Procatarſis, or preceding indiſpoſition of the Blood, the aforeſaid Diſtempers, rarely, or not at all, cauſe a Putrid Feaver.

As to what reſpects the Squinancy, Pluriſie, the Inflammation, or Impoſthume of the Lungs, and the like; I ſay, that theſe are the products of the Feaver, or Diſtempers following it; but by no means the cauſe of it: for moſt often the evident Cauſe, went before, which produced the feaveriſh Effervescency of the Blood, as a taking of cold, evacuation being hindred, *&c.* then, although the ſick do not openly grow preſently into a Feaver, yet a greater ebullition of the Blood, than was wont, is ſtirred up, as may be eaſily conjectured from the Urine, Pulſe, and inquietude of the whole Body. After ſome days (now ſooner, now later) an Inflammation is brought forth in one part or other; the reaſon of which, may probable enough be ſaid to be of this ſort: The Blood, by reaſon of the *Effluvia* being retained (which are like ferment) is increaſed in its bulk, and grows more turgid than its wont, in the Veſſels; and when for want of Ventilation, it is ſtreightned in the ſpace of its Circulation, it eaſily ſprings forth, where it can find a paſſage, through the Arteries, and being extravaſated from the broken Thred of Circulation, it gathers together into a Tumor; and becauſe from this kind of tumor an heat and pain are increaſed in the part, the Blood is more diſturbed in its motion, and ſo the Feaver, at firſt inkindled, is more aggravated.

Further, in theſe kind of Diſtempers, we may take notice of a certain aptitude of the Blood to be coagulated, whereby it is made leſs fluid, ſo that it is apt to be congealed in the leſſer Veſſels, even as it is to be perceived in Milk, when it begins to ſowr, for then it will not be boiled, nor heated over the fire, without coagulation: and in like manner, there is to be ſuſpected in the Blood, a certain diſpoſition to growing ſowr, by reaſon of which, it is made more obnoxious to coagulation; for it eaſily appears, that in a Pluriſie, a Peripneumonia, the Squinancy, and the like Diſeaſes, the Inflammation, or Extravaſation of the Blood, does not always depend on the exuberancy of the Blood, and plenitude of the Veſſels; for oftentimes the Blood is ſtopped in its motion, with a weak Pulſe, and a ſinking down of the Veſſels, and being extravaſated in the ſide, or elſewhere, cauſes a moſt acute pain, yea being driven from one part, by and by it is fixed in another; and ſometimes it begins to ſtagnate in the Heart it ſelf, and there oftentimes induces a deadly oppreſſion: wherefore, ſome pluritical people, are wont, when the pains are gone, to complain of a great burden, and as it were weight, fixed about the Region of the Heart: And when we have opened the dead Bodies of ſuch as have died of theſe kind of Diſeaſes, we have ſeen the Blood to be gathered together, in little bits, or oblong gobbets, in the ſecret parts of the Heart, and round about the cavities of the Veſſels. But for that theſe Diſeaſes are wont to be handled apart from the Feaver, therefore we ſhall ſay no more of them here.

It only remains, that we enquire, whether the Feaver which accompanies theſe Diſtempers, is to be eſteemed in the rank of thoſe that are called putrid, or not? To which we reply, that moſt often they are ſimple Feavers, in which only a ſubtil and ſpirituous part of the Blood is inflamed; and therefore if the extravaſated Blood may be reſtored to Circulation, by a plentiful detraction of the Blood, or an emptying the Veſſels by Sweat, preſently the growing hot of the Blood is appeaſed, and the Feaver ſhortly allayed. But ſometimes, when a prediſpoſition, as in a Plethora, or fulneſs of good humor, or in a great Cacochymy, or fulneſs of evil Juices, brings it on, together with the ſame kind of Diſtempers, a putrid Feaver is inkindled, wholly from the ſame Cauſe.

Among

Among the Symptomatick Feavers, is reckoned that which is commonly called the ſlow Feaver; they who are ſick of this, are more than uſually hot, eſpecially after eating, any motion, or exerciſe; the Urine for the moſt part is red, the Spirits are feeble, and ſtrength caſt down; as to their Appetite and Reſt, they are indifferently well, they have neither Cough, nor much Spitting, but they daily (like thoſe in Conſumptions) grow lean without any evident cauſe. The fault for the moſt part is aſcribed to Obſtructions in ſome Inward, (as the Liver, Spleen, or Meſentery) by whoſe default the Aliment is not well Cooked, nor rightly diſpenſed. But it ſeems to me, that this ſort of diſtemper is immediately founded in the evil diſpoſition of the Blood, by which it is inclined into a too ſalt and ſowr temper, and therefore is rendred leſs apt for nutrition and an equal Circulation. For the Blood in the Heart, juſt like Oil in a Lamp, if it redounds too much with ſaline Particles, is enkindled not pleaſantly and equally, but with a noiſe, and great evaporation of the parts; whereby indeed, it is ſooner waſted, and exhibits but a languiſhing and weak flame. I opened one, ſometime ſince dead of this Diſeaſe, in whom the Viſcera deſtinated to Concoction, were well enough, but the Lungs were without moiſture, and dry, and beſet throughout with a ſandy matter like Chalk. Alſo oftentimes, in this Diſeaſe, the Meſentery is beſet, the Glandules being filled with ſuch a Chalky matter: but whether the Blood being made more ſaltiſh, doth firſt bring in theſe kind of Diſtempers of the Viſcera, or whether the Dyſcraſie, or evil diſpoſition of the Viſcera, firſt brings it upon the Blood, is uncertain: it ſeems probable, that either Diſtemper depends upon the other, and that the cauſes of either evil are reciprocal.

Bnt the Feaver, which chiefly deſerves to be called Symptomatic, is that which is excited in Phthiſical perſons, from an Ulcer or Conſumption of the Lungs. For the whole Blood, whilſt it paſſes through the Lungs, in its Circulation, often impreſſes on this Inward, the Idea's of very many Diſeaſes; and on the other ſide, receives the ſame from it, being evilly affected, whatſoever impure thing is contained in the Maſs of the Blood, as the flowring of new Wine, is caſt forth by extremities of the Arteries; wherefore, when Nature being made more weak, it cannot transfer its recrements into the ſuperficies of the Body, it depoſes them by a more near Purgation into the Lungs. From hence a Cacochymia, or fulneſs of ill Juices, and many Chronical Diſeaſes end in a Conſumption: in like manner, when the fleſh of the Lungs waſtes, or abounding with an ulcerous Matter, becomes palf putrid, the Blood paſſing through it, is infected with the purulent matter, or tabid infection, and for that cauſe, is ſtirred up into a continual Effervescency, by reaſon of the confuſion of ſomething not miſcible, and wherefore it induces an aſſiduous Feaver, and wholly perverts the Alible Juice. The ſame reaſon is of Feavers, from an Ulcer or Impoſthume, oftentimes raiſed up in other parts; for theſe, even as the tabid conſtitution of the Lungs, cauſe oftentimes a Conſumption and Hectick Feaver. The full conſideration of theſe are not for this place; wherefore we will return whence we have digreſſed, to a Putrid Feaver properly called, or eſſential,

The Eſſential putrid Synochus is wont to be divided into a putrid (ſuch as is already deſcribed) into a Cauſon, or hot burning Feaver; and beſides into a Quotidian, Tertian, and Quartan: The putrid Synochus, but now delineated, ought to be the rule or ſquare of the reſt, to whoſe Type moſt Feavers, which are of this kind, are to be compoſed. As to the reſt, but now mentioned, according as they vary their kind, I ſhall briefly ſubjoin.

The Cauſon, or burning Feaver, is that which performs its courſe with a greater heat, almoſt intolerable thirſt, and other Symptoms, arguing a greater inflammation of the Blood: The formal reaſon of it, by which it is differenced from the reſt, conſiſts in this; that the temper of the Blood is hotter, that is, abounds more with fireable Sulphur; therefore, when it grows fervent, it is enkindled in a greater plenty; and with its deflagration, diffuſes the *Effluvia* of a moſt intenſe heat, through the whole Body: its motion is acute, and quickly comes to its ſtanding; it is compaſſed about with more horrid Symptoms, hath a difficult Criſis, and an even full of danger.

But as to what reſpects thoſe periods or fits, in which a putrid Feaver ſometimes is wont to be more cruel at a ſet time; and (as if intermitting) now every day, now every third or fourth day, repeats as it were the Feaveriſh fit; the reaſon of this ſeems not eaſily to be explicated; eſpecially if we reject from this cenſe the fewer humors, to the ſpontaneous motion of which, this Diſtemper is commonly aſcribed, concerning this matter, what ſeems moſt likely to me, I ſhall doubtingly propoſe. In a continual Feaver there are two chief things (as we have already noted) which for the moſt part induce the Effervescency of the Blood, to wit, the exaltation and enkindling of the Sulphureous part of the Blood; then conſequently an heaping together of the aduſt matter, and remaining after the burning of the Blood, to a ſwelling up: upon the former a continuance of the Feaver, upon the other, its ſtanding, and critical perturbations depend: To theſe ſometimes, a certain third thing happens, to wit, a fulneſs, and ſwelling up of the crude Juice, from the Aliments newly taken, which in a continual Feaver (as in the fits of intermitting Feavers) induces a great Effervescency at ſet intervals of times. But why this does not always happen, nor wholly after the ſame manner,

the reaſon is this; when the putrid Synochus is very acute, and the whole Blood almoſt is quickly inflamed, and highly rages, whatſoever of nutricious Juice is poured to the blood, is preſently burnt and conſumed by the fire; wherefore little or nothing of it is contained in the maſs of blood, for the matter of a fit. But if this Feaver be leſs acute, and the blood only flames forth moderately, and in parts, the ſupplement of the crude Juice is not wholly conſumed by the burning; but is perverted by a more gentle fire, into a fermentative matter, which, when it ariſes in the Veſſels to a fulneſs of ſwelling up, conceives a Flux, and by its Effervescency, makes ſtronger the Feaveriſh heat, before glowing in the bloud, as it were by the coming of new Fewel. The flowring of this matter doth not ſeldom begin with a light ſhivering, or cold, and ſometimes end with ſweat; but for the moſt part, it is exhaled by inſenſible tranſpiration. In every fit, beſides the proviſion of the degenerate nutricious Juice, ſomething from the aduſt, and burnt matter of the blood, evaporates; wherefore the Criſis of the Diſeaſe is drawn forth longer, that 'tis hardly cured, under eleven or fourteen days; yea (for the moſt part) in this ſort of Feaver, with fits and remiſſions coming between, the perfect Cure of the Diſeaſe happens ſcarcely within twenty days; and ſometimes leiſurely, without any through Criſis, it remits, and then by a long declination, it is ended in Death, or Health.

But that this kind of remiſſion and acerbation or growing more violent, are varied, according to the type of an Intermitting Feaver, that they repeat their turns now every day, now every other day, and ſometimes not but within four days, the reaſon of this is to be ſought, from the Doctrine before delivered, of Intermitting Feavers; to wit, that according as the Dyſcraſie of the Blood diverſly appears, the ſupplement of the degenerate nutritious Juice, ariſes to the fulneſs of ſwelling up, either ſooner or later; and for that reaſon, its Effervescency cauſes now more frequent, now more rare fits in this Feaver.

Concerning the Cure of putrid Feavers, of every kind, there are four general intentions, on which the whole ſtreſs of the matter depends.

Firſt, That the Blood (if it may be done) may be defended from burning, and the flame, or fire enkindled in its Sulphureous part, be wholly ſuppreſſed; which about the firſt beginning of this Diſeaſe, happens to be brought often about.

Secondly, That when the Blood having taken fire, cannot be preſently extinguiſhed, that at leaſt it may perform its burning more mildly, and with leſſer hurt.

Thirdly, The deflagration being ended, that the Liquor of the Blood be freed from the recrements of the aduſt and burnt matter, and afterwards reſtored to its natural Temper and Vigor.

Fourthly, That the Symptoms chiefly troubling may be timely helped, the which, unleſs taken away, will fruſtrate the work both of Nature and Medecine.

As to particular Remedies, with which theſe intentions may be ſerved, there are various preſcriptions, and forms of Medecines, not only among Phyſicians, but alſo among old women and Emperics, ordinarily in uſe; from which, however, like a Sword in a blind mans hand, uſed without difference, and exact method of healing, more hurt than good, moſt often accrues to the ſick. There will be no need here to repeat the forms of Purges, Cordials, and of other Medecines, elegantly enough delivered among many Authors: I will add in few words, ſome chief indications, and Medical Cautions, which ought to be obſerved in the courſe of this Feaver, according to its various times, and divers ſymptoms.

1. At the firſt beginning of this Diſeaſe, the buſineſs will be, that the Feaver may be preſently ſuppreſſed; and the inflammation of the heated Sulphur may be inhibited; to which, the opening of a vein doth chiefly conduce; for by this means, the Blood is eventilated, and the heated Particles, too much heaped together, and almoſt ready to be fired, are diſſipated one from another: as when Hay, apt to burn, if expoſed to the open Air, its firing is prevented. Beſides, let a ſlender Diet be inſtituted, in which nothing Spirituous or Sulphureous ought to be adminiſtred: The Viſcera, and firſt Paſſages ſhould be freed from the load of excrementitious matter; wherefore Clyſters are of neceſſary uſe; ſometimes alſo Vomits and gentle Purges; by which, ſometimes timely and with Judgment adminiſtred, the Feaver preſently after the beginning, is extinguiſhed, the food of the fire being drawn away. If that notwithſtanding this method the burning ſpreads more abroad, and more and more, daily ſnatches hold of the Sulphureous Particles of the Blood; it muſt be endeavoured (as much as may be) that the deflagration proceed gently, without great tumult.

2. When the Feaver is augmented, if the Blood be too hot, and diſtends the Veſſels very much, with a vehement and ſtrong Pulſe; if Watchings, a Phrenſie, or a pain of the Head cruelly urge, the letting of Blood may be again repeated; Tranſpiration (as much as may be) ſhould be freely procured; wherefore let the ſick keep in bed for the moſt part; let the Diet be ſparing, of the moſt ſlender Aliments, alſo Drink ſmall, and plentiful, that the burning blood may be diluted with a more plentiful Serum: Clyſters are adminiſtred ſafe enough, and in truth commodiouſly; but Medecines, whether Catharticks, or Diaphoreticks, and which too much exagitate the Blood, are to be ſhunned, with the ſame induſtry, as Blaſts of Wind to burning Houſes;

Houſes; but rather Opiats, and Anodines which fix and bind up the Blood and Spirits, are to be made uſe of; alſo Juleps and Decoctions, which refrigerate the burning Viſcera, attemper the Blood, and cheriſh the Spirits, are often to be exhibited; acetous Liquors of Vegetables, or Minerals, alſo putrified Nitre, becauſe they reſtrain the rage of the Blood, and extinguiſh Thirſt, are truly convenient. Hot Waters, and Spirits, Cordial, and Bezoartick Powders (ſo long as the Diſeaſe is not malignant) are not to be medled with. If that the Blood be unequally circulated, and is carried more towards the Head, than the Feet, Epithema's are Profitable, of the warm Fleſh, or Inwards of Animals, applied to the Soles of the Feet.

3. When the Feaver is at its ſtanding, the motion of Nature is diligently to be attended, whether it will make a Criſis or not; wherefore nothing raſhly is to be attempted by the Phyſitian; the opening a Vein, or ſtrong Purgation, is wholly to be forbid; but after that the Feaveriſh burning is ſomewhat remitted, from the deflagration of the Blood, and ſigns of Concoction appear in the Urine, if that the motion of Nature be ſlow, a Sweat, or gentle Purge may be admittted; which however, are better and ſafer done by the Phyſician, when Nature firſt, by a critical motion, hath entred upon the ſecluſion of the Morbifick matter. If that all things are crude, and troubled, the Urine yet turbid, without ſediment, or ſeparation of parts, if the ſtrength be languiſhing, the Pulſe weak, if there be no Criſis going before, or only in vain, any evacuation, either by ſweat or Purge, is not to be attempted, without manifeſt danger of Life, but it muſt be longer ſtaid for, that the Spirits of the Blood may recover themſelves, may by ſome means overcome the excrementitious and aduſt matter, and then by degrees may ſeparate it, and put it forth; in the mean time, the Spirits are to be cheriſhed, with temperate Cordials, the immoderate Efferveſcency of the Blood (if it ſtill be) is to be ſtopped, and its due fermentation ſuſtained, which in truth is beſt performed by Corals, Pearls, and ſuch kind of Powders; which indeed are diſſolved by the Ferments of the Viſcera, and then ferment with the Blood, and greatly reſtore its weak and wavering motion. In the mean time (whilſt Nature is labouring) all obſtacles and impediments are to be removed, and eſpecially the proviſion of Excrements, heaped up in the firſt paſſages, is to be brought away, by the frequent uſe of Clyſters.

4. By what way or method, the Symptoms chiefly urging, ought to be handled, will not be eaſily preſcribed by certain Rules; becauſe they themſelves require ſometimes to be preſently appeaſed and qtieted, and ſometimes to be quickned forward: and what is ſomething more, perhaps at another time, they are to be left wholly to Nature. Some of theſe are to be oppoſed with gentle and lenitive Remedies, but others with more ſharp and irritative Phyſick: yet in the mean time it is a precept to be held in all, that you diligently wait upon the footſteps of Nature; which if it works wrongfully, its diſorder is to be reduced; if rightly, yet too vehemently, to be bridled: If ſhe works rightly, yet too ſlowly, or more weakly than ſhe ſhould, the buſineſs will be, that her endeavour may be incited, and helped, by the help of Medecine.

5. In the declination of the Feaver, when after a perfect Criſis, Nature is ſtronger than the Diſeaſe, the buſineſs goes well, nor is there much buſineſs left for a Phyſician: It only remains to propoſe an exact manner of Diet, that the ſick may ſoon recover ſtrength, without fear of relapſing: alſo it is requiſite to exterminate the Reliques of the feaveriſh matter, with a light Purgation. About Diet, they often fall on the Rock of Relapſing, *viz*, by the too haſty eating of fleſh-meats, or more ſtrong food, the ſick relapſe into the Feaver; for when the Viſcera are weak, and the Aliments (unleſs very ſlender) not eaſily digeſted, and when alſo the diſpoſition of the Blood is weaker, that it does not aſſimilate the more ſtrong nouriſhing Juice, if any thing improportionate is brought to either, the Regiment of Nature is again perverted, and all goes ill. Wherefore, thoſe growing well, ſhould for a long time refrain from fleſh, and when at length they uſe it, it ſhould not be unleſs the Urine ſhall be like that of healthful people, and no more troubled by the cold; and then indeed it will be ſafeſt to begin with Broths made of Fleſh, and then by degrees, to proceed to more ſtrong Aliments.

6. When from an imperfect Criſis, things are grown doubtful, and remain yet undetermined; then is the Phyſicians moſt difficult Task: The motions and ſtrength of Nature are carefully to be waited on, whether it begins to prevail on the Diſeaſe, or to yield to it: If ſigns of concoction appear, and that there is ſtrength, a gentle evacuation, and only by leiſure, is to be celebrated. In the mean time, the Symptoms moſt urging are to be ſuccoured with convenient Remedies, all impediments to be taken away, and ſtrength is to be ſuſtained (as much as may be) with Cordials, and a right manner of Living or Diet.

7. When from an Evil, or no Criſis, all things turn to the worſe, and when the Phyſician almoſt deſpairs of curing the Diſeaſe, he may predict its event ſuſpected, and much to be feared. But yet, he ought not to truſt to a naked Prognoſtication, to hinder all things elſe, but that as yet, what is in the Medical Art, ſhould be conſulted for health, though deſperate: Remedies may be adminiſtred to the Symptoms moſt infeſting; the Spirits of the Blood almoſt extinct, may be reſtored by Cordials. When we deſpond of Health, Life ſhould be prolonged as long as tmay, and at leaſt a fair Exit procured.

According

According to the various types but now deſcribed, of a Putrid Feaver, I might readily add very many Hiſtories of ſick people, and particular obſervations, made about their Cure; for for theſe kind of Examples are uſually met with in our daily practice, ſo that they are ſufficient to fill a great Volume; out of theſe however, with the good leave of the honeſt Reader, I will briefly propoſe ſome few, reſpecting the ſeveral kinds of the aforeſaid Feaver, by which their Doctrine, and Method of healing them, above delivered, may be illuſtrated.

A Noble Matron, about fifty years of Age, of a ſlender habit of Body, litlte ſtature, indued with a ruddy complexion, when on the fifteenth day of *June*, by reaſon of the Summers heat, ſhe had put on more thin Garments than ſhe was wont, felt her ſelf ill in the Evening; from thence ſhe was diſtempered with a nauſeouſneſs, and oppreſſion of her ſtomach, ſhe felt wandring pains, troubling her now in her ſhoulders, now in her back, very thirſty, yet without any immoderate heat: on the ſecond, and third day, almoſt after the ſame manner, on the fourth day after a Vomit, *viz.* of the infuſion of *Crocus Metallorum*, one Ounce given, ſhe caſt forth yellow bile four times, and had three Stools, and ſeemed to be eaſed, the night following, ſhe ſlept ſomething better: but on the next day, the Feaver being throughly inkindled, ſhe complained of thirſt, a burning of the Præcordia, and of a pain, now in her ſide, now in her back; preſently blood was taken to eight Ounces, her Urine was of a very deep red, thick, and troubled without any Hypoſtaſis, or ſetling of the Contents, her Pulſe unequal, and often intermitting, the following night without ſleep: on the ſixth day of the Diſeaſe, early in the Morning, a ſmall Sweat broke forth, from whence the heat ſomething abated, which in the Evening again grew ſtronger: on the ſeventh day, a very acute heat, with thirſt, burning, an inordinate and intermitting Pulſe, as alſo with a mighty reſtleſneſs, and toſſing of the whole Body troubled her, on the eighth the ſymptoms were ſomewhat more remiſs; alſo in the Urine, ſome marks of an Hypoſtaſis; ſhe took that day Poſſet-drink, with Meadow-ſweet boiled in it, and ſweated plentifully; and was cured of her Feaver. All the time of her ſickneſs, for Food they gave only ſmall Beer, Poſſet-drink, Barly-Broth, or Grewel, alſo frequently Clyſters; Drink, and a cooling Julep, they gave her at her pleaſure.

This Noble Lady, through tranſpiration being hindred, fell into a putrid Synochus: the *Effluvia*, wont to be evaporated through the Skin, being retained within (together with the Choler flowing out of the Choleric Veſſels) and fixed to the Viſcera, did overthrow the diſpoſitions of their parts, and eſpecially gave trouble to the Stomach, and raiſed up pains and Convulſions in the parts filled with Muſcles and Membranes: the Pulſe was unequal, and intermitting, not becauſe of the maligaity of the Diſeaſe, as in the Plague, but by reaſon a certain proper diſpoſition of the Heart, by which indeed, its ferment being not well conſtituted, the Blood growing fervent, is not preſently equally enkindled, and wholly leaps forth, but a part of the Blood, in flowing in a ſmall, then a greater, and after ſome turns, the greateſt proportion, ſtopping for a moment of time, in the boſoms of the Heart, produces the unequal or intermitting Pulſe. I have known in many others, clearly, the like Diſtemper of the Pulſe; to wit, ſo long as they were free from intemperance, the Pulſe was altogether equal and orderly, but if they were more ſtrongly heated than uſually, by any ſudden paſſion of the mind, or too great agitation of the Body, , preſently they were affected with an unequal Pulſe, and between the vibrations or ſtrikings, intermitting perhaps 4, 7, 10, or 20. and as often as they fell into a Feaver, the Pulſe ſhewed it ſelf after this irregular manner. When this habitual irregularity concerning the Pulſe, was not yet made known to me, by frequent experience, I was wont to ſuſpect ſtill a malignity in the Diſeaſe, and to foretel a fatal event, which happened otherwiſe.

On the fifth day, in this ſick perſon, the Feaver, although ſlowly enkindled, came to an augmentation, and from thence paſs'd through the reſt of the ſtations with a ſwift motion; on the ſixth light emptying of the aduſt matter, ariſing to a fulneſs, a Sweat being riſen, and ſo a certain remiſſion of the Feaveriſh heat followed: on the ſeventh day, this aduſt matter ariſing to its height of increaſe, made the ſtanding of the Diſeaſe, to which, at length on the eighth day, a plentiful Sweat, with all things requiſite to a good Criſis, followed, and perfectly cured the Feaver: becauſe (as it ought to be) thoſe three things went before this critical evacuation, *viz.* firſt a full and ſufficient deflagration of the Blood, as appeared by the very ſtrong heat, and plainly fiery, continued for three days before; alſo ſecondly, a congeſtion of the aduſt matter to a plenitude, as was collected by the high diſquiet and toſſing about the preceding night: and then a certain Pepaſmus or Concoction of the ſame matter, and a begun ſecretion in the Blood, which a ceaſing of the Symptoms and Signs of Concoction in the Urine, ſhewed; wherefore, the copious Sweat, coming upon ſo laudable a ſign, ſo long as there was no ſuſpition of malignity, portended nothing but good.

About the beginning of the year 1656, a Gentleman endued with an active habit of Body, without any manifeſt cauſe (unleſs that being much addicted to ſtudy, he uſed no exerciſe after it) became ill; at firſt he complained of a nauſeouſneſs and want of Appetite, with a great Head-Ach, on the ſecond day he was affected, now with a ſhivering, now with heat, ſeveral times reciprocating, beſides, with thirſt, and burning of the Præcordia, with a ſcurfineſs of the Tongue,

Tongue, and an ingrateful ſavour. On that day, he took ten drams of an Emetick Liquor, by which he vomited ſeven times and caſt up a great quantity of yellow bile, and had four Stools; the night following he was unquiet, and almoſt wholly without ſleep, and in which the ſick perſon grew more Feaveriſh, with an increaſed heat: on the third day, when the aforeſaid Symptoms were grown worſe, he was let blood to ten ounces; his Urine was red, thick, and with a copious ſediment; his Pulſe quick, and vehement; at night he ſweat a little with a ſhort ſleep, but diſturbed: on the following morning, he ſeemed to be a little eaſed; yet in the evening all things grew worſe, with moſt ſtrong wakings, heat, and thirſt: on the fifth day, by a light Sweat, the heat ſomewhat remitted, which yet a little before the Evening, returned with its wonted fierceneſs. The Night again was wholly without ſleep, with a continual toſſing up and down of his Body. In the Morning, by a little gentle Sweating, he felt a little eaſe; in the Evening an increaſe again of all things more cruelly; the night alſo was very unquiet: about the beginning of the next day, a Sweat, as before ſucceeded, and a little more plentifully: on this day was a manifeſt change towards Health; the heat and thirſt was a little leſs vehement, his Urine was leſs red, with ſome Hypoſtaſis; thence, for three days, the Feaver leiſurely declined; yet every night he had a certain fit, but more remiſs than before; on the eleventh day, he ſweated more plentifully, and was perfectly cured: all the time of his Sickneſs, he uſed a moſt ſpare diet, taking truly nothing of Aliment, beſide ſmall Beer, and Poſſet-drink made of it; he ſometimes took Drink and cooling Juleps of boiled Barly, and diſtilled waters; daily, if his Belly was not looſe of it ſelf, an emollient Clyſter was adminiſtred: he uſed no other Phyſick beſides, no wit, neither Purge nor Cordial. But the Feaver being allayed, he was twice Purged, and from thence quickly well.

This Feaver was a putrid Synochus, as may be conjectured by the ſhivering about the beginning, and then with continual heat, thirſt, watchings, and other Symptoms grievouſly infeſting for many days: but foraſmuch as its intemperature was exaſperated every night, it might be called a continued Quotidian This Diſeaſe made its firſt aſſault without any evident cauſe, becauſe the Blood being little ventilated, like Wine growing hot of it ſelf, had conceived an ardour, from the exalted Sulphur; the Choler flowing forth from the Choleduct Veſſels, and likewiſe the Purgings of the raging Blood, being poured about inwardly (as it is wont to do for the moſt part in Feavers) preſently ſtirred up troubles and diſorders in the firſt paſſages; therefore by reaſon of the excrementitious matter there heaped up, there was procured a depletion, and ſoon after the beginning, a Vomiting: notwithſtanding which Evacuation, and likewiſe a more ſtrong purging of the Belly by Stool, if adminiſtred, the Feaver being wholly inkindled, becauſe they too much agitate the Blood, and diſturb greatly the Concoction of the aduſt feaveriſh matter, for that reaſon bring more dammage for the moſt part, than benefit to the ſick: The firſt ſtation of this Diſeaſe, *viz.* until the whole Blood was fired, was extended to the third day; and then from thence, when the Blood flaming forth, was burdened with aduſt recrements, its greater ebullition, with a frequent endeavor of expulſion by Sweat, followed, on the ſeventh day, when the Blood for the greateſt part had flamed forth, and the aduſt recrements, heaped up in its boſom to a fulneſs of ſwelling up, began to be troubleſom, the critical motion was ſtirred up; by which nevertheleſs, that matter not being as yet wholly ſubdued, nor ready for ſeparation, the Diſeaſe was not perfectly cured; but after another period, the ſame increaſing, at laſt being ſtirred up, on the eleventh day, brought on that other, and perfectly curing ſwelling up: in the days between, becauſe, beſides the recrements remaining after the deflagration of the Blood, and reſerved for a Criſis, alſo from the Nutritious Juice not preſently taking fire, but after a peculiar manner depraved, other matter in the boſom of the Blood, apt to a ſwelling up, was gathered together; therefore, from the continual increaſe, and Flux of this, there hapned to this Feaver continual fits (ſuch as are wont in intermitting Feavers) on ſet days and hours.

A ſtudious young man, about twenty five years of Age, of a dark Countenance, and Melancholic temper, without any manifeſt occaſion, began to be ſick, in the Year 1656. At firſt he complained of a Feaveriſh Diſtemper with thirſt, a ſpontaneous wearineſs, and want of Appetite; moreover, on the ſecond day, of a pain in his right ſide, and a diſtention of either Hypochondrium, alſo with almoſt continual Vomiting, Wakings, and very great pain of the Head; a Phyſician being ſent for, he was preſently let Blood to twelve ounces. In the Evening he grew more hot, and was light-headed; afterwards, a Sweat, though ſmall ſucceeding, he was better the next Morning: on the fourth day again, he caſt up whatever he took preſently; alſo he was troubled with an almoſt continual endeavour of Vomiting. The exhibition of a Vomitory Medicine, propoſed by the Phyſician, both the ſick perſon, and alſo his Friends, taught by the danger of it before, rejected. From a Clyſter given him, he had ſix Stools, and ſeemed to be a little alleviated; alſo the night following he ſlept ſomewhat: on the fifth day he again fell into frequent Vomiting, with intolerable Thirſt; he burnt inwardly, but outwardly could not be felt any immoderate heat; becauſe the recrements of the effervent Blood, which ought to exhale through the Skin, ſeemed to ſtagnate within, and to

flow

flow forth into the Viſcera. Therefore in the evening this Bolus was given him, to provoke Sweat. Of Conſerves of Roſes Vitriolate one Dram, of *Gaſcon*'s Powder one Scruple, of Laudanum ſoluted in Balm-Water one Grain: that night he ſlept moderately, and by a copious ſweat following, the Symptoms ſeemed to be mitigated: nevertheleſs on the ſixth day, all things again were imbittered, and a through heat, thirſt, and burning of the Præcordia, cruelly tormented him; on the ſeventh and eighth day, the Puſe was unequal and diſordered; for the moſt part he talked idly, and if moved in his Bed, he fell often into a Swoon. On the ninth day, the ſame Symptoms ſtopped, alſo he was troubled with a contraction of the Tendons in his wriſts, and convulſive motions of other parts, that we almoſt deſpaired of Life. Becauſe that morning Nature ſeemed to be given over as conquered, ſhe was now to be ſuccoured, with whatever remained of Art: Wherefore intending a more copious Sweat, as the laſt Refuge, I gave him a Dram of Spirit of Harts-horn, at one time, in a ſmall draught of Cordial Julep; upon which, being for four hours very unquiet, and furious, he could ſcarce be held in his Bed: but afterwards Sleep creeping upon him, he ſweat very much, and the buſineſs ſuddenly came to be out of all danger, On the following night, for the continuing of the Sweat, I ordered to be given him, every ſix hours, a doſe of the Powder of Contrayerva, the Feaver, and the Diſtempers of the Nerves ſhortly ceaſed, and the ſick perſon became well.

This Feaver, as to the manner of its Figure, may be called a putrid Synochus; which, in this ſick perſon, from the Blood being made hot of its own accord, like Hay heating, and ſo conceiving an immoderate Fermentation, took its original: by reaſon of the Melancholick temper of the Blood, the heat was leſs ſtrong, although the Symptoms were otherwiſe worſe, and happened to be chiefly inimical to the nervous ſtock; for the Blood burning forth, as Fire in a Furnace, covered with Chips, glowed with a moſt inteſtine burning; therefore the ſick complained of the heat of the Præcordia, with an intolerable thirſt, when in the mean time, the exterior parts were bu little heated: for this reaſon, and becauſe the Body was leſs perſpirable, the aduſt recrements of the Blood being about to make a Criſis, and which were wont to be diſperſed outwardly, at ſet times, being ſuffuſed inwardly (Nature being very much oppreſſed, and perpetually provoked) brought on cruel, and almoſt continual Vomitings; wherefore, when the Feaveriſh matter was derived to the firſt paſſages, by ſo frequent an endeavour of its expulſion, before the fulneſs, or concoction, no Criſis followed thereupon. Nor was the ſick man the better for that irregular evacuation; yea, the Blood being ſtill made worſe in its mixture, began to be corrupted in it ſelf, and wholly to pervert the Nervous Liquor; from whence, beſides the aſſiduous Vomitings, frequent Swoonings, inequal Pulſe, alſo Deliriums, and Convulſive Motions did ariſe; but foraſmuch as the mixtion of either humor and diſpoſition, being not yet wholly looſned, or overturned, the Diaphoretick was adminiſtred, which by reaſon of its great agility, quickly paſs'd through both the Blood, and the Nervous Liquor, and a lively and haſty Fermentation being raiſed up anew, carried forth of doors their impurities and extraneous mixtures; the ſtate of the Diſeaſe tending towards Death, was reduced to Health, and by this means, inſtead of a Natural Criſis, by the help of a ſupplying Medecine, the ſick man, as it were recalled from the dead, quickly recovered Health.

A Woman, being about thirty years old, of a ſtrong Body, and Melancholick temper, (as might be gathered by her very auſtere manners) in the third month after her lying in, got cold in giving her Child ſuck, and uncovering her ſelf, and upon it fell preſently into a ſhivering. To this, a heat more increaſed than uſual, followed, which afterwards (a light Sweat ariſing) quickly remitted. On the ſecond and third day, ſhe was very thirſty, and without appetite to Food, yet without immoderate heat, that ſhe could ſcarce believe her ſelf in a Feaver: She lay quiet every night, but wholly without ſleep; her Urine was highly red, and with the multitude of Contents, thick and cloudy, which however not troubled by the Cold, remained ſtill after the ſame manner, without Hypoſtaſis, or ſinking down of the parts. On the fourth day, the heat was inkindled throughout the whole; wherefore a Phyſician being then firſt ſent for, about 12 ounces of Blood was taken from her Arm; after the letting of blood, and her Belly the ſame day copiouſly emptied, by a Clyſter, in the evening ſhe fell into a Sweat, by which nevertheleſs ſhe was nothing eaſed, and (though an Anodine Medecine was given her) ſhe wore out the whole night (as before) without ſleep. On the fifth day, from a Clyſter being given, ſhe had three Stools, and felt ſome eaſe: her Urine ſtill remained red and troubled; when Blood was preſcribed to be taken from her Ham, the ſick obſtinately refuſed, eſteeming her ſelf to grow well: on the following night, when ſhe had lain long without ſleep, and unquiet, ſhe at length was troubled with a fit, ſuch as is commonly called Hyſterical, after a grievous manner; and at firſt, with a certain numneſs or ſenſe of pricking poſſeſſing the extream parts of her body (eſpecially her feet, thighs and legs) ſhe was affected; and together with a Wind cruelly diſtending the Inteſtines, Ventricle and Hypochondria; ſhe felt in the bottom of her Belly, as it were a certain bulk to creep upwards, which when it had aſcended to the Heart, and thence to the Brain, the ſick Woman preſently was weakned in her Intellectuals, and all the night lay talking extravagantly and idly. On the ſixth day, after her Belly was taken down by a Clyſter, ſhe returned to her ſelf, and remained

remained in her right mind, and ſeemed to be indifferently well. But in the Evening when ſhe was moved in her bed, ſhe began to feel the ſame kind of fit as before, to wit, ſhe had a ſenſe of pricking, as if ſtung with Nettles, in all her body, together as it were a round thing rouling about in her belly, which creeping upwards, diſtended the Inteſtines and Ventricle, that ſhe emitted by means of it blaſts, and belchings: for eaſe ſake, ſhe required a draught of cold Water. Moreover, the Remedies uſual in hyſterical Diſtempers, as Caſtor, the ſmell of *Aſſa fœtida*, the fume of burnt Feathers, Ligatures, and Frictions of the Legs, and the like were adminiſtred, by the uſe of which, ſhe ſeemed for the preſent, free from the aforeſaid Diſtemper, and was wholly without it for four hours: but when ſhe lay upon her back in her bed, as ſhe had ſetled her ſelf to ſleep, on a ſudden ſhe complained, that the ſame Symptoms, did at once run through her whole Body, and by and by, ſhe fell upon it into a Delirium; houling and crying out, ſhe talked idely the whole night; the day following, her eyes being open, ſhe lay without ſpeech or motion: again in the Evening, when her Feaver being increaſed, ſhe grew furious, that ſhe could ſcarce be held in her bed: and ſo ſhe remained for three days, now delirious, crying out, and wailing, now as it were ſtupid, without motion, or voice; yet ſtill ſhe was tormented with Convulſive motions, about the tendons of the muſcles: on the tenth day, ſhe drew her breath deep, and difficultly, with a weak, and as it were a creeping pulſe, and about the middle of the night died.

This Feaver was of the rank of the Putrid Feavers, which nevertheleſs, by reaſon of the melancholic diſpoſition of the Bloud, (as we before intimated) was not very grievous, with heat or burning; but yet being very much infeſtous to the Brain, and nervous ſtock, was more difficult to be cured: The Bloud being prediſpoſed to a growing hot, eaſily contracted the Diſtemper by taking cold, but yet, from the ſalt, and earthy feculencies, together with the Sulphur being moved, it was not openly inflamed; nevertheleſs, burning with an inteſtine, and as it were ſhut up fire, it was more notably depraved: Hence, preſently from the beginning, the Urine was highly red, and troubled, alſo ſhe continued wholly without ſleep: on the fifth day, the Bloud burning forth, and being filled with the recrements, or aduſt matter, was irritated by its plenitude to an endeavor of excretion; wherefore, this night, a ſwelling up being ariſen, it transferred its load, not diſperſable by ſweat, into the head, and there affixed it to the Brain, and nervous ſtock: From thence, preſently, the wonted irradiation of the animal Spirits, being diſturbed in the fountain it ſelf, their inordinations firſt hapned to be felt in the extream parts; wherefore, there was a pricking in the whole Body, the Belly inflated, the Hypochondria diſtended, and as it were a certain ſubſtance, or live thing, aſcending upwards, and ſucceſſively running through the Belly, Precordia, and at length the Head: For theſe kind of Symptoms, ariſe not (as it is commonly believed) always from Vapors, lifted up from the Womb, and ſtriving or thruſting upwards: but, not ſeldom, from the Brain, and the beginning of the Nerves being diſtempered: for, when the evil is there inflicted, that the animal Spirits nigh their origine, are diſturbed in their motion, neither (as before) blow up, and diſtend the nervous Bodies, preſently the other Spirits, implanted in the extremities of the Nerves, being deprived of their wonted influence, begin to tumultuate, and being moved inordinately, and towards their beginnings, cauſe Convulſions in thoſe parts in which they dwell. This irregular, and Convulſive motion, begun in the extremities, by the continued paſſage of the Spirits, and of the nervous parts, creeps by and by into other parts, and then to others, ſtill to thoſe nearer to the Brain, till at length, (the whole ſeries of Spirits, like Souldiers, being carried ſucceſſively backwards) the Convulſions are continued, into the fountain it ſelf of motion; So as in truth, by this means, the Convulſive motions, are ſometimes begun, a moſt long way, from the cauſe, or place of the Diſtemper, as by this only argument plainly appears: to wit, as often as the influx of the animal Spirits, is inhibited in the Leg, or Arms, by a ſtrict Ligature, or by leaning hard on them, a ſenſe of pricking, or a cramp, with a numneſs, is felt, firſt in the Foot or Hand, which afterwards ſucceſſively aſcends towards the affected part: wherefore, in this ſick Woman, by reaſon of the Feaveriſh matter, (to wit, the aduſt recrements) fixed on the Brain, by a critical tranſlation from the boſom of the Bloud; and there beſetting the beginnings of the Nerves, thoſe Symptoms, imitating the hiſterical diſtemper were ſtirred up: by reaſon of the Nerves, (which are diſperſed through the whole Body, by means of the Spinal Marrow) being diſtempered near their original, the ſenſe of pricking begun in the extream parts, by and by is perceived in the whole. By reaſon of a like hurt, of the ſixth pare in the fountain, Convulſions and Diſtentions ariſe, firſt in its little branches, moſt thickly ſet about the Abdomen: That aſcent, as it were of a certain ſubſtance, was only a tumefaction of the Viſcera, and Muſcles, ſucceſſively inflated or blown up, by the Convulſion; from thence, the ſame Diſtemper (by the mediation or coming between of the branch of the ſame ſixth pare) creeping along more upward, and ſtill more near the Brain, the Precordia, and then the Head it ſelf, (as by a certain Vapor raiſed up from beneath) ſeemed to be taken; on the next day, when this Feaveriſh matter, at firſt lightly fixed in the Brain, was at length again amended by the Bloud, the aforeſaid Symptoms ceaſed for a time: Then ſoon after (the Bloud

again flowing, and depoſing its Recrements again in the Brain) the ſame kind of Diſtemper as before, this ſick Woman felt to come upon her; which however, with rubbings, the ſmell of ſtinking things, and other Remedies uſed in the hiſterical paſſion, was retarded for four hours, from its aſſault; to wit, foraſmuch as the animal Spirits, being tyred out by the external object, and irritated into a violent motion, were hindred, that they could not ſo ſuddenly conceive Convulſive motions: but afterwards, when that incitation of the Spirits, outwardly exhibited, did ceaſe, the morbific cauſe ſtill troubling, thoſe Spirits being grievouſly beſet, not ſucceſſively (as before) beginning at the extremities, but on a ſudden, all, both in the Brain, and the nervous appendix, were at once acted into confuſion. The Criſis being after this manner attempted, *viz.* By the tranſlation of the Feaveriſh matter to the Brain, the event of the Diſeaſe, both in this ſick Woman, and alſo in others, whoſe ſickneſſes I have diligently obſerved, for the moſt part hath a mortal ſucceſs. For the Bloud, unleſs extreamly depraved, and hindred, ſcarce ever endeavors to purifie it ſelf, by ſuch a Criſis: and as often as it endeavors an excretion by this means, it inflicts on the Brain, and nervous ſtock, an evil, not quickly, nor eaſily to be blotted out: alſo, the maſs it ſelf of the Bloud, very rarely, by the motion of ſuch a flowring, is rendred free, from the impure mixture of the Feaveriſh matter.

A learned young man, of a lean habit, and pale countenance, in the coming in of the Spring, being conſcious of no error as to his dyet, began to complain of a wearineſs, and impotency in walking, alſo of a drouſineſs, and ſleepineſs of his head: on the ſecond day alſo, he was tormented with thirſt, want of appetite, and an heat of his Precordia: on the third day, the Phyſician being ſent for, he took a Vomit, by which, when he had Vomited three times, and caſt downwards five times, cholerick and hot matter, he became ſomewhat chearfuller, and the night following ſlept indifferently well: on the fourth day, he bled a ſmall quantity; then his thirſt, and heat very much increaſed: his Urine was red, with a copious ſediment, and a little hypoſtaſis. But becauſe, after the ſigns of concoction in the Urine, the endeavour of Nature, as it were oppreſſed, appeared for ſeparation, without ſufficient evacuation, therefore he was let Bloud to ſeven Ounces, and he ſeemed thereby to be very much eaſed, yet in the evening, all things grew worſe, and then for three days, the Feaver ſeemed ſtill to be increaſed: on the ſeventh day, he complained of a great heavineſs in his head, and of a darkneſs, turning about in his eyes: after noon, an hemorrhage or bleeding copiouſly followed, that for the great loſs of Bloud, the ſick perſon had almoſt loſt all his ſtrength, and there was a very great neceſſity of medicinal help to ſtop the Bloud: For this end, when a Vein in his Arm was opened, Ligatures, and proper Medicines were applied, both to his Head and Belly, and very many other Remedies (the occaſion of haſty curing urging) preſcribed by every body, were tryed in vain; at length, by the perſuaſion of a Woman, coming there by chance, a red hot Iron was held to his bleeding Noſe, and on a ſudden, from the Vapour of the burnt Bloud, received into the Noſtrils, its Flux was ſtayed. This Remedy, I afterwards knew uſed to many, with very good ſucceſs. This great Hemorrhage cured the continual Feaver, to which nevertheleſs, an intermitting Quotidian followed, which afterward was quickly cured, by the method of curing already delivered.

This Feaver, beginning without any manifeſt occaſion, and continued for many days with thirſt, and heat, may be called a Putrid Synochus; which yet without any horrid Symptom, about the beginning or ſtanding, was cured by an eaſie courſe, tho' at length by a dangerous and difficult Criſis: The turgeſcency of the Bloud in the Spring-time, and together the defect of ventilation in the ſame, gave the beginning to this: The Bloud burning out, with a Feaveriſh fire, about the fourth day, had heaped up ſomething of aduſt matter; that flowring it attempted a critical motion, tho' with a ſmall hemorrhage: The defect of a more full evacuation, the opening of the Vein ſupplied for a time, afterwards, the aduſt Recrements being heaped together, in great plenty, the ſame being not apt to be diſſipated by ſweat, in a body not rightly perſpirable, at the time nature was about to endeavour a Criſis, a mighty bleeding followed. For when the Bloud, by reaſon of the ſecluſion of the Feaveriſh matter, is agitated with a critical motion, very many of its Particles are looſned from the mixture, ſo that a greater ſwelling up being provoked, they carry forth every extraneous thing confuſed with them: if at this time, the breathing places of the skin, be but little open, the maſs of the Bloud (as new Wine ſtopped up in a bottle of a ſmall mouth) even more notably grows turgid, and becauſe it cannot ſhake off the Feaveriſh matter, by ſweat, it carries it ſelf forth of dores, together with it, any way it can find; wherefore, when there lies a moſt eaſie paſſage, for the boiling Bloud, through the veſſels opening into apertures of the Noſtrils, from that Port (like the ſame new Wine when the veſſel is opened) being inlarged by a ſpumous refraction, it abundantly leaps forth. The continual Feaver being cured, by this means, an intermitting Quotidian followed, becauſe after a long deflagration of the Bloud, and great loſs of it, what Bloud was remaining, being very much deprived of Spirit, and the Salt, with the left Sulphur being throughly roaſted, eaſily contracted that kind of diſpoſition, whereby it was apt, not rightly to concoct the alible juice, but to pervert it into a matter very fermentative.

A Matron

A Matron, about ſixty years of age, when ſhe had ſat up a certain night, going to bed in ſheets, not throughly dry, began to be ill; at firſt ſhe was troubled with a ſuffocating Catarrh, that by reaſon of the ſerous deluge, falling on the Sarynx, ſhe could hardly breath; neither could ſhe ſleep; the next day with a nauſeouſneſs, and want of Appetite, with ſome little exceſs of thirſt and heat: on the third day, an acute pain invaded her in her ſide, with a Cough, and the Feaver increaſed: her Urine was red, and clear, with a laudable Hypoſtaſis, an unequal, and an intermitting pulſe. A Phyſician being ſent for, ſhe was let Bloud to ten ounces, alſo that day, her belly was copiouſly looſned by a Clyſter: About night the pain vaniſhed, and ſhe ſlept indifferently: her Urine was then red, troubled, and full of contents: on the fourth day, the Feaver was ſomewhat increaſed: In the evening troubled with a Cough very much, and by and by following thereupon the acute pain (as before) in the ſame ſide; her Urine being again clear, with an Hypoſtaſis: Her pain, from her being let Bloud again ceaſed; on the fifth day, the Feaver was more remiſs, but at night ſhe was unquiet with heat, and a toſſing up and down of her body, but without pain. The next morning ſhe ſweated plentifully, and was eaſed; then uſing ſtill a ſlender dyet for ſome days, and being once purged, ſhe grew well without relapſing. It is worth obſervation, that whilſt the pain troubled her, the Urine was clear, and with an Hypoſtaſis, nor troubled by the cold; which however, the ſame being allayed, became preſently thick, more red, and filled with contents.

This Diſeaſe, becauſe of the acute pain in the ſide, as it were a Pathognomic ſign, might be called a Pluriſie: but we have here a Feaver, preceding the pain, and not the product of it; The evident cauſe of the ſickneſs was Tranſpiration being hindred by the conſtriction of the pores; The Bloud growing hot, by reaſon of the *Effluvia* being retained, and alſo too much abounding with a ſerous latex, as it were vomiting very much of it, from the Arteries terminating in the Larynx, cauſed the ſenſe of the ſuffocating Catarrh: For this kind of Diſtemper (as alſo the Cough with great ſpitting) ariſes not, for that the watery humor (as is commonly ſaid) falls from the head, into the throat, and lungs; but becauſe the ſerous Latex is poured forth, now from the pneumonic veſſels, immediately into the lungs, now dropping forth from the Arteries opening into the Larynx, falls down on the breaſt; on the third day, from the ſame ſerous humour, with a portion of the Bloud, being fixed in the ſide, the acute pain aroſe; for the Bloud beginning to grow fervent, when as yet it did contain in it ſelf a crude matter, and (as it ſhould ſeem) ſomething ſour, from the degenerate alible juice, depoſed the ſame, (becauſe it could not caſt it forth of doors by ſweat) by a proper luſtration or purging through the intercoſtal Arteries, into the Membrane ſurrounding the Ribs; and there (as it is always wont in a Pluriſie) either by coagulation, (which may be lawfully ſuſpected) or by the ſhutting up of the veſſels, the Bloud being intangled with the ſame matter, is ſtopped in its motion; then being increaſed in its bulk, by a new coming ſtill of the Bloud, it cauſes a break of the union, and ſo an acute pain. That in this ſick Woman, the ſame kind of matter, diſturbing the maſs of Bloud, with a portion of it extravaſated, was fixed about the Pleura, it from thence hapned, becauſe the pain urging, the Urine was clear, and not full of contents: then when the veſſels, by reaſon of Phlebotomy, being emptied, they ſupped up again that matter, into its maſs, before exterminated from the Bloud, the Urine preſently became troubled, and again big with contents: The pulſe was unequal, and intermitting, becauſe of the idiocraſie or proper diſpoſition, which ſhe was wont to have in every intemperature: for when I cured this Woman of a Feaver, many years before, her pulſe being unequal, and intermitting, had ſtruck a fear in me, and others, of a ſad preſage, concerning the event of the Diſeaſe, which however at that time, (as alſo in this ſickneſs) ceaſed, proſperouſly, and without any horrid Symptom.

A ſtrong young man, and corpulent, after immoderate Exerciſe, about the Summer ſolſtice, and then a ſudden cold coming upon the heat, found himſelf ill: At firſt, a want of Appetite, nauſeouſneſs, and cruel pain of the head, as alſo thirſt, and a more intenſe heat than uſual troubled him; on the ſecond day, an acute pain invaded him on his right ſide with a Cough, and difficult breathing; Bloud being preſently taken plentifully from the Arm of the ſame ſide, that pain remitted ſomewhat, which yet in the evening returned, being made more cruel by a Cough, and bloudy Spittle. The night followed, without ſleep, and very unquiet: on the third day, he was again let bloud, beſides Liniments and Fomentations were applied to his ſide; Moreover, Pouders, Juleps, and anti-pleuretick Decoctions, being taken inwardly, about night the pain almoſt wholly ceaſed. Then by and by, he was afflicted with a cruel Head-ach, and a Vertigo: on the fourth day, a ſtream of Bloud fell from his right noſtril, about two ounces, by which the pain of his Head clearly ceaſed, and the Vertigo; but in the Evening, the pain in the ſide before diſtempered, returned with greater fierceneſs: In the mean time his Pulſe was ſmall, and weak, that when it was conſulted upon, for the letting him bloud again, 'twas thought dangerous, leſt his dejected ſtrength would not admit of ſuch Remedy: wherefore, Phlebotomy was performed only, in a very ſmall quantity, and a Fomentation, and a Cataplaſm was preſcribed to be diligently applied to his ſide; beſides twenty drops of the Spirit of Harts-horn, to be taken in a

ſpoonful of Cordial Julep, and the ſame to be repeated continually, within the ſpace of ſix hours: He ſweat that night very much, and the pain much remitted, his ſpitting was but little, interſperſed with Bloud, which, within a day wholly ceaſed, and the pain alſo leiſurely vaniſhed. The ſick man took twice a day, a ſcruple of the ſame Spirit of Harts-horn, and within a few days, he grew perfectly well, without relapſing.

This Feaver was a ſimple Synochus, ſtirr'd up from the evident cauſe, *viz.* a Conſtriction of the Pores: as ſoon as the Bloud began to be ſomewhat filled with the aduſt Recrements, and ſo to ſwell up more, the matter, which ſhould have been ſeparated, by reaſon of its peculiar evil, was tranferred into the Pleura, and being there fixed, compelled the Bloud coming to it, to be coagulated, and therefore to be ſtopped in its circulation, and (when it could not be received by the Veins) preſently to be extravaſated: from hence hapned the acute pain in the ſide, and bloudy Spittle, by and by, after the beginning of this Diſeaſe; then afterwards, the ſame matter being thruſt out of that neſt, which it had got, and being ſupped up again into the maſs of Bloud, was fixed in the head; and there inducing the like ſtagnation of the Bloud, and (as it is probable) coagulation, cauſed the Vertigo, and cruel pain; which nevertheleſs was quickly cured, by the hemorrhage being ariſen, by reaſon of the extravaſated Bloud. A part of the morbifick matter, being after this manner drawn away, the other part reſumed by the Bloud, was again conveyed to its uſual neſt, to wit, the ſide before diſtempered; where depoſiting its Latex, (to wit, a portion of the Bloud) it did coagulate it again, and compelled it to be extravaſated, or to flow out of the Veſſels: For that pain being renewed on the fourth day, with the bloudy Spittle, from the ebullition of the Bloud, too extreamly, and therefore flowing out of the Veſſels, would not be brought away; becauſe at that time, the Pulſe was ſmall and weak, with a falling down of the Veſſels, that indeed the Bloud was thought to have been run all out of the Veſſels, for that being coagulated by the morbific matter, (and therefore tho' expulſed the Arteries, yet not being able to be carried back by the Veins) it was ſtopped in its circulation. Upon this, an acute pain followed, becauſe the Bloud being heaped together by its frequent approach, and elevated into a Tumor, made a diſſolution of the union; alſo, by and by from the beginning, a bloudy Spittle came upon it, becauſe the Bloud being reſtrained within, in the Body, ſomewhere in its motion, by reaſon of the moſt tender, and eaſily opening little mouths of the Veſſels, ran forth into the Cavities; when to the ſame outwardly extravaſated, by reaſon of a more thick skin, and the mouths of the little Veſſels being locked up, no way lay open, unleſs by its being made and ripened into an Impoſthume. The opening of a Vein profited in the beginning of the Pleuriſie, becauſe it reſtrained the Bloud, ſomewhere hindred in its circuit, from too great effervescency; but eſpecially, for that, when the Veſſels were by that means greatly emptied, they did again receive, and render fluent, whatſoever humors were before exterminated, and alſo the Bloud beginning to ſtagnate in the diſtempered part. Alſo, the Remedies helping moſt, about the beginning of this Diſeaſe, were of that ſort, which hinder the coagulation of the Bloud, or diſſolve it in the coagulating; ſuch they are, which abound very much with a volatile, or an alchaliſate Salt: to wit, Spirit of Soot, of Bloud, Harts-horn, alſo Spirit and Salt of Urine, the Pouder of the Claws and Eyes of Crabs, of a Boars Tooth, or the Jaw of a Pike, are of known uſe. Among the Common People, it is a cuſtom to drink an Infuſion of Horſe-Dung; which Medicine indeed, I have known often to have brought help, in deplorable caſes. In the mean time, all acid things whatſoever, becauſe they more coagulate the Bloud, and hinder expectoration, are highly hurtful in this Diſeaſe.

CHAP. XII.

Of a Malignant or Peſtilential Feaver in general.

BEſides the continual Feaver, which is already deſcribed, and which ariſes from ſome principle of the Blood being too much carried forth, there is another ſpecies of this, which is ſtirred up, by reaſon of the Bloud being touched with ſome invenomed Infection, and therefore liable to enter into various coagulations, and corruptions: In which, not only the Spirit and the Sulphur, as in a Putrid Feaver, rage, and compel the Bloud to grow immoderately hot, but beſides, the mixture of the Bloud is preſently diſſolved, and its liquor goes into parts; and ſo moſt horrid Symptoms, with manifeſt danger of life, are induced in this ſort of diſtemper. Under this rank, we comprehend Malignant, and Peſtilential Feavers, the Plague, Small Pox, and Meaſles: of which we ſhall ſpeak preſently.

Peſtilential

Peſtilential Diſeaſes, wander ſo in the dark, and have an unknown original, that their cauſes, and beings are ſeldom explicated, without having a recourſe to occult qualities. By the unanimous conſent of all, the ſtrength, and power of theſe are placed in an invenomed matter; becauſe we perceive, from a peſtilent diſtemper, ſtrength ſuddenly to be overthrown, and life quickly deſtroyed, no otherwiſe than from the drinking of Poyſon. And therefore, for the explicating the nature of the peſtilence, it will not be beſides the matter, firſt, to enquire concerning Poyſon in general, and by what means it diſtempers our Bodies, then to ſhew what ſort of Poyſon is ſprinkled in the Plague, and contagious Diſeaſes: which being performed, we will treat particularly of the Diſeaſes but now recited.

Every thing deſerves the name of Poyſon, which ſtriking into our Body, after an occult manner vehemently hurts the temper, and actions of any part, or of the whole, profligates the Spirits, or perverts their motions, ſolves the mixtures of the Liquors, and induces Coagulations and Corruptions, deſtroys the functions and ferments of the Viſcera, and ſo ſuddenly and hiddenly brings life into danger. Of theſe, which after this manner lie in wait for us, there is a mighty plenty, and very rich proviſion in the nature of things: oftentimes they are inwardly begotten within our body; outwardly they are abundantly ſupplied from every Coaſt, and out of every tract of Earth, Water and Air, theſe daily ariſe out of the diſtinct families of Minerals, Vegetables, and Animals, and ſo mingle themſelves with our Food, yea, with our Medicine, that we may complain with *Pliny*, *Quod non ſit fateri, an rerum natura largius mala, an remedia genuerit.* That it was not known, whether Nature had begot greater Evils, or Remedies.

As there is great varieties of Poyſons, ſo, as to their Subjects, and ways of hurting, there is no leſs diverſity of them: for the moſt Poyſons, in their whole ſubſtance are ſaid to be contrary to us, that whatſoever they come to, with a burning force, and like fierce fire, they reduce into aſhes, yet out of theſe, ſome being noted for a peculiar raiſing of hurt, do more endammage one one part or ſubſtance than another. The Subjects, on which the taint of Poyſon, is next and more immediately inflicted, are twofold; to wit, the animal Spirits, or the ſpirituous ſubtil Liquor flowing in the Brain, and nervous ſtock; and the Bloud flowing in the Veſſels, and Heart, when the object is carried only to one, or being improportionate, at one to either, that from thence, the diſpoſition of the Liquors, or of the containing parts, is overthrown, whereby the neceſſary functions, for the performing of life and ſenſe, are reſtrained, and this done latently, and as it were unforeſeen, theſe kind of Diſtempers, we aſcribe to Poyſon.

The nervous Bodies, with the animal Spirit, are not invaded wholly after the ſame manner, by every ſort of Poyſons; for they are tormented, now with a Stupor, now with Convulſions, and thoſe of divers kinds and manners: The Bile of a Tarantula, cauſes dancing: A Power ſent from the Torpedo, by the Angle, or lines of the Net, ſtupifies the hand of the Fiſher. The Roots of the Wild Parſnip, or the Seeds of Lolium or Darnel, being eaten, make men mad: Opium, Mandrakes, Henbane, and the like, cauſe deep, and ſometimes deadly ſleep. Theſe and many others, chiefly impreſs their Poyſon, on the ſpirituous or animal faculty, without any great perturbation of the Bloud, or hurt brought to the heart.

There are alſo ſome Poyſons, which moſt of all inſinuate their malignity, to the maſs of Bloud; wherefore, from ſome Medicines, there have been produced, a yellow or black Jaundice, ſometimes a Leproſie, or leprous diſtempers, and ſwellings of the whole body, vapours breaking forth from ſecret hollows of the Earth, alſo from Coals newly inkindled, often ſuffocating the vital Spirits, at once congeal the Bloud, and ſtop it in its motion, whereby the flame of life in the heart, could not be continued. How much corruption of the maſs of Bloud is imparted from the peſtilent Infection, is perſpicuous to every one, from the Spots and Whelks, which are as it were the marks of the blaſted Bloud.

If the hurt, being firſt inflicted to either, *viz.* The regiment of the Heart, or Brain, be more lightly made, it is for the moſt part cured, without any great offence to either; wherefore, Convulſive Motions, Stupefaction, Lethargy, Melancholy, Paralytick Diſtempers, do not ſeldom begin with a laudable Pulſe, and without an immoderate effervescency of the Bloud; and then, if the diſtemper does not get ſtrength, leiſurely end, and ceaſe. There are other Poyſons, which often deprave the Bloud, and by diſſolving its mixture, corrupt it, in the mean time the animal functions remain whole enough. But if the ferment of the Poyſon be ſtronger, and hath more deeply fixed its roots, preſently the Poyſon is diſperſed, from one Province to the other: for when the nervous parts ſwell up, with a virulent juice, a portion of the Poyſon, is carried with the nervous Latex returning through the Lymphatick Veſſels, into the Veins, eaſily into the boſom of the Bloud, and infects its maſs, with the evil with which it was big: alſo, from the Bloud being grievouſly impoyſoned, the juice, by which the Nerves are watered, quickly contract the infection; hence mad men are in a Feaver, and thoſe taken with a peſtilent Feaver, are moſt often tormented with a Delirium, or Phrenſie. Concerning theſe things, we muſt conſider, what the alteration is, or the impreſſion of hurt, which is inflicted from the Poyſon, to the animal Spirit, with the brain and nervous appendix; and what alſo, to the Bloud, with the Heart and the annexed Veſſels: tho' here, it is not in the power of humane skill or wit, plainly to ſhew, or

as it were point out with the finger the manner of its being done; yet we may be able to attain to ſome little knowledge of this thing, by reaſoning, and by comparing it, with other diſtempers.

Concerning the former, we ſhall obſerve, that the ſubtil Liquor, or animal Spirits, wherewith the Nervous Bodies are blown up, and by whoſe expanſion, ſenſe and motion perform their reciprocal actions, are eaſily perverted from their tenſity, and equal expanſion: for as the Nerves are of a ſoft texture, and the Spirits which abound in them of a very ſubtil ſubſtance, they cannot endure any ſtrong or vehement objects; wherefore when any violent or improportionate thing falls on them, they are often compelled from their expanſion, and excurſion into flight, and a running backward, and not ſeldom into irregularities of motions: wherefore ſudden paſſions of the mind diſtract them, and drive them into Spaſms, and Convulſions; when the Alible Juice, by which they are repaired, is ſupplied too ſharp, ſour or auſtere, they ſuffer now Palſies, and now Contractures: If that ſome object more incongruous, (ſuch as we have affirmed Poyſon to be) ſhould be offered, whoſe Particles are indued with ſuch fierceneſs, or are of ſuch a kind of configuration, that when they grow impetuouſly hot with the Nervous Liquor, they ſhake or loſe here and there its more ſubtil or ſpirituous part, or wholly drive it away, and fix the remaining Liquor either with a ſtyptic force, or by ebullition, force it into inordinate motions; hence of neceſſity, evil diſtempers of the Brain, and Nervous parts ariſe, *viz.* ſometimes a Convulſion, Trembling, Shivering, ſometimes looſnings, or a ſtupefaction, and other ſymptoms of more grievous note. What things after this manner infect the Nervous Juice with Poyſon, are now more thick, and only when they are applied in a very Corporeal ſubſtance, do inflict their hurt; now they are thin, and being reſolved, even into a vapour or breath, pour forth from a certain little prick, the ferment of Poyſon, through the whole Nervous ſtock. Sometimes the Poyſon of ſome hurtful thing, being eaten, firſt begins its Tragedy in the Ventricle; more often by a naked touch, leaves on the ſuperficies of the Body, a virulent taint, which eaſily and quickly with its ferment, contaminates the Spirits, diſperſed through the whole. The infection, whereever inflicted, either within or without, is more largely diſperſed from the extremities of the Nerves, by their eaſie paſſage, being from thence brought into conſent of the evil, by the very many little ſhoots of the ſame branch. Often a more light touch of an invenomed thing, by the finger, or extremity of any other member, preſently communicates to the Brain, the received infection, and from thence it is retorted into the whole Body, and the fartheſt members; the reaſon of this is, that both the Particles of the Nervous Juice, and of the ſame invenomed infection, are ſo light, and ready for motion, that they paſs through moſt ſwiftly, as the Rays of light through a Diaphanous medium, the whole maſs of one another.

2. As often as the Bloud contracts hurt from ſome Poyſonous thing, the Poyſon is fixed within; either ſlow, and of leſſer activity, which does not preſently betray it ſelf, nor break forth into cruel ſymptoms, till of a long time after, it is ripened by a ſilent fermentation, and hath firſt infected the whole maſs of Bloud, as may be obſerved in ſome Poyſons, which are ſaid to kill at a diſtance, and not till after ſome months or years. Or the Poyſons inſpired into the Bloud, are imbued with a much more acute ſting, that from their Contagion, the Infection contracted, preſently breaks forth into cruel ſymptoms, and thereupon follows now a Feaveriſh effervency with Vomiting, Thirſt, and burning of the Precordia, now a ſwelling up of the whole Body, a diſcoloration of the Skin, oftentimes a breaking forth of Whelks, and Buboes, and frequently alſo a ſudden loſs of all ſtrength, ſo that ſudden death, without tumult, and almoſt inſenſibly ſteals upon one: where by the way it is to be noted, If the Spirits of the Bloud, provoked by the enemy, are able to encounter him, and to ſtrive for the victory, this Feaveriſh ebullition of the Bloud is ſtirred up from the conflict; but if the Particles of the Poyſon, being far ſtronger, ſuddenly profligate the Spirits of the Bloud, and extinguiſh life, preſently the bloudy maſs is corrupted, neither can it be circulated in the Veſſels, nor rightly inkindled in the heart.

If it be yet demanded, what mutations, the Bloud infected with Poyſon, undergoes, either in its ſubſtance, or conſiſtency, that, for that reaſon it is rendred unfit for the ſuſtaining of Life? I anſwer after this manner; Some Poyſons fuſe the Bloud, and too much precipitate its ſeroſity, ſuch are Medicines, which by a ſtrong killing Purging, or by a *Profluvium* of Urin, or a diſcoloration, or ſwelling up of the whole Body, or with an eruption of Puſtules, cauſe a very great ſecretion of the ſerous Latex; in the mean time a great ebullition of the maſs of Bloud is induced, whereby the Vital Spirits are greatly deſtroyed, the Particles of Salt and Sulphur too much exalted, by the concoction, and are often ſo roaſted, that a Yellow or Black Jaundice is cauſed.

There are Poyſons of another kind, far more dangerous, which congeal the Bloud, and by deſtroying its mixture, corrupt it, *viz.* the firſt induce a congelation to the bloudy maſs, and then a Putrefaction: for when the Spirits of the Bloud, being overthrown, by the contagion of the Poyſon, are diſſipated, the equal mixture of the Liquor is looſned; wherefore the more thick Particles mutually infold one another, and (like Milk, when Rennet is put to it, or growing ſowr of it ſelf) are coagulated apart: hence the Bloud curdles in the Veſſels, that it is

leſs

leſs readily circulated in them: coagulated portions of this, being inwardly diluted, into the boſom of the heart, are apt to ſtagnate there, and ſo to bring forth frequent ſyncopes and ſwoonings: being carried outwardly, and in the circulating, fixed in the skin, ſometimes being more plentifully heaped together, they induce a ſuffuſion of blackneſs through the whole, ſometimes being more ſparingly diſperſed, they cauſe only ſpots, or Purple marks, like black and blue ſtroaks, and other appearances of malignity. But the coagulation of the Bloud, quickly diſpoſes it to putrefaction or corruption; as is ſeen in extravaſated Bloud, which is wont to grow ſoon black and putrid. For the Spirit being exhaled, the Particles of Sulphur and Salt remaining in the Bloud, begin to go apart one from another, and to break the bond of the mixture, from whence follows Putrefaction.

Theſe things being thus premiſed of Poyſon in general, the reaſon of the method requires that we enter upon the handling of Feavers, which draw their Original, altogether from a malignant, and invenomed infection: and as under this title, the Peſt or Plague eaſily obtains the chief place, I will begin with its conſideration, and afterwards, I will ſpeak of Malignant Feavers, Small Pox, and Meaſles, in order. But yet, before I ſhall propoſe its definition, I will briefly inquire, of the peſtiferous Poyſon, what its Diſpoſition and Nature may be; alſo, from whence it may be born; and laſtly, by what means it is propagated into others, by contagion.

For the expreſſing the Nature of the Plague, Authors are wont to chuſe ſome invenomed Bodies, and from their Names, to frame an Elogy of this moſt wicked Diſeaſe; wherefore in the definition of the Peſt, are commonly recounted the Nepelline, Aconital, and Arſenical Poyſon: the Lethiferous force of which however, as it conſiſts in a very thick matter, and does not exert or put forth it ſelf but by a Corporal contact, doth not truly imitate the eſſence of the Peſtilential Diſeaſe: for this is founded in a Spiritual and Vaporous Infection, by which its *Effluvia* being every way diffuſed, ſo potently unfold themſelves, that out of the beſt ſeminary or ſeed-plot, they quickly propagate a fruitful Crop of Death and Deſtruction. By reaſon of its notable activity, this Infection may deſerve to be called, as it were a certain quinteſſence of Poyſon; the very agil and ſubtil Particles of this, do penetrate all Bodies, and inſpire them with its ferment: for either being diſperſed through the Air, or hid in a certain tender or cheriſhing neſt, tho' they ſtrike againſt the humane Body but lightly, and as it were through a Caſement, they eaſily ſubdue it; for both the Animal Spirits, and thoſe of the Bloud, they quickly infect, and by that means, ſhortly pour forth the venomous taint, into all the members.

When a Peſtilential Breath or Vapour, hath invaded any one, and that Poyſon hath firſt laid hold on the Animal Spirits, or thoſe of the Bloud, or both of them at once, (as hath been already ſaid of Poyſons) the taint is quickly derived from the ſubtil and more thin ſubſtance of theſe, into a more thick matter: becauſe it quickly ferments the whole Maſs of Bloud, or of the Nervous Juice, and the Excrementitious Humors, every where abounding, and from thence is deduced into the ſolid parts, and fixes the evil in them. If this Diſeaſe, firſt poſſeſſes the Animal Spirits, preſently the hurt is communicated to the Brain, and the Nervous ſtock, and eſpecially to the Ventricle, forthwith it impoyſons the humour growing in theſe; looſens its mixture, perverts the regular motion, and renders it wholly incongruous and infeſtous to the more tender ſubſtance of the containing parts: by and by from thence, Cramps and Convulſive Motions, cruel Vomitings, pains of the Heart, alſo Phrenſies, Deliriums, or pertinacious Watchings, are ſtirred up, about the firſt aſſault of the Diſeaſe: when in the mean time, the infection not being yet diſperſed through the Bloud, the ſick are not Feaveriſh, nor are troubled with inordinate Pulſe, or Syncope, or appearances of marks; which ſymptoms however ariſe afterwars, as ſoon as the Bloud is infected. If when the Spirits of the Bloud are firſt poſſeſſed, with the impoyſoned infection, either drawn in with the Air, or attracted through the Pores, its ferment is preſently diſſipated through the whole Maſs of the Bloud, the infeſted portions immediately begin to be looſned from their equal mixture, to go into parts, and to be coagulated, and the ſame, being delated, into the boſom of the Heart, are wont there to ſtagnate, and ſo to induce a Syncope, Swoonings, and often ſudden Death; alſo being carried outwardly, fixed about the skin, to cauſe Buboes, inflamed riſings, and other marks of Poyſon; in the mean time, the ſick appear well in mind, nor are they troubled with Delirium nor Convulſive Motions. If that from a more ſtrong cauſe, the hurt is inflicted to both parts at once, the courſe of the Diſeaſe is performed with a more horrid proviſion of ſymptoms, and eſpecially with a Syncope, and Phrenſie at once infeſting.

As to what appertains to its riſe; when the Plague firſt ariſes in any Region or Country, there is attributed a two-fold cauſe of it, *viz.* Primary or Metaphyſical, alſo Secondary or Natural, ſubordinate to that: The very Heathens did acknowledge this Diſeaſe, wherever it raged, ſent firſt of all from God, for the caſtigation of the wickedneſſes of men, and therefore for its extirpation, they equally made uſe of Prayers and Sacrifices as of Medicines. As to what belongs to the Natural cauſe, there are divers opinions. Some will, that the Peſtilence newly ariſen, be

derived

derived from the Heavens, and influences of the Stars only: on the contrary, others have affirmed it only to ariſe from the internal putrefaction of the humors of our Body: but theſe endeavour to deduce the cauſe of this ſickneſs too far off, and theſe more near than it ought. We will walk in the middle way, and what reaſon perſuades, and what very many Authors aſſert, we will place the chief and firſt ſeminary or ſeed plot of this Poyſon, in the Air; becauſe, it ſeems conſonant to Reaſon, that from the ſame Fountain, from which the common food of life is had, the beginnings of death, no leſs diffuſive, are to be ſought. There is the ſame neceſſity for our breathing in the Air, as of Fiſhes living in the Water; wherefore, as to Waters infected by Poyſon, the Murrain of Fiſhes dying in heaps is aſcribed; ſo Men dying of an Epidemical ſlaughter, without any manifeſt cauſe, nothing could kill, beſides the Infection of the commonly inſpired Air.

For the Air, which we neceſſarily draw in for the continuance of Life, conſiſts of an heap of Vapors and Fumes, which are perpetually breathed forth from the Earth; in which the exhalations of Salt and Sulphur, being mingled with the atomical vaporous little Bodies, conſtitute here as it were a thick cloud: the motions of theſe are ſwift and unquiet, they are of a manifold figure, and very much diverſe, wherefore ſome continually meet againſt others, and according to their various Configurations, they cohere with theſe, and are mutually combined one with another, and from thoſe they are driven, and fly away: from hence the reaſons of the Sympathy and Antipathy of every thing, depend. From the diverſe Agitations of theſe kind of Atoms, near the Superficies of the Earth, this or that Tract of the Air, enters into diverſe alterations, by which, Bodies, chiefly the living, are variouſly affected: becauſe the inteſtine motion, of the Particles of every Animal, depends very much upon the motion and temper of the Particles of the Air: foraſmuch as theſe perpetually exagitate thoſe, raiſe up thoſe lying aſleep, repair the loſs of thoſe flying away, ſhake the vital flame with their Nitroſity, and ſupply it with a Nitrous-Sulphureous Food, eventilate its being inkindled by continual turns of acceſs and receſs, and carry away the Soot and Fumes. So long as an apt contemperation happens in either, for motion and configuration, living Creatures injoy perfect health and life; but if the little Bodies ſwimming in the Air, be of that ſort of figure and power, that are plainly adverſe to the Spirits implanted in living Creatures, they looſe the mixtures of theſe, from the reſt, from whoſe Elements they are collected, and pervert their motions; hence the diſpoſitions of things are deſtroyed, life profligated, and, the ſame being ſcarce extinct, the Bodies undergo putrefaction; hence the tops of Trees, or of Corn, being ſtruck with a blaſt, ſuddenly grow dry or wither; hence, among Cattel, the Murrain often rages, which kills at once whole Flocks; by reaſon of this kind of cauſe, the Seeds of the Peſtilence firſt put themſelves forth, and attempt the ſlaughter of humane kind: for as invenomed Bodies in the bowels of the Earth or concreted on its ſuperficies, produce the Arſenical or Aconital mixtures, ſo theſe being even reſolved into vapour, and heaped together in the Air, create moſt pernitious Airs, from which Malignant and Peſtilential Diſeaſes ariſe; the infection, which after this manner Contaminates the Air, the moſt ingenious *Diemerbrochius*, a ſearcher of this Diſeaſe, contends, that is only ſent (as the wrath of angry *Apollo*) immediately from the angry right hand of God: but this were to multiply without any pretext of neceſſity (I will not ſay beings but) Miracles, and in every Plague to aſſert a Creation of new ſubſtance; when in the mean time, the virulent product of Minerals and Vegetables, which daily appear, and of as quite adverſe Nature to us, as the Plague, clearly teſtifie, that there lives hid in the Bowels of the Earth, plenty of invenomed matter, ſufficiently fitted for this buſineſs. For the little Bodies, which being rouled about with earthy matter, do conſtitute the Poyſonous mixtures in the boſom of the Earth, the ſame being reſolved into vapours, will be no leſs hurtful afterwards, and impreſs a peſtiferous blaſt to the Air, which they wander through: wherefore, by the leave of ſo Learned a Man, I ſhould ſay, that it ſeems not improbable, that the things which firſt of all affix the ſeed plot of the Peſtilence, to any tract of Air, be the Poyſonous *Effluvia* of fierce Salts and Sulphurs, and (by the Divine Will inſtigating) breathing forth from the bowels of the Earth; which ſometimes, being a long time before ſhut up, are leiſurely exhaled out of Dens and Caverns; ſometimes by reaſon of the motion of the Earth, or Earthquake, or a gaping of the Earth, they break forth in heaps; alſo, of the ſame kind, are thoſe which ordinarily are breathed forth from the filth of Souldiers in their naſty Camps; or from unburied Carcaſes; or from places, beſet with ſtanding and ſtinking Mud: but the little Bodies after this manner exhaled, obtain their wonderful height, properties, and abilities, by a long putrefaction, that therefore they are incongruous, and heterogeneous to all others whatſoever, and ſo being received into the Air, ferment it (as it were a maſs of Liquor) and pervert it from a wholſom and benign, into a moſt pernicious and wicked Nature.

Some Bodies more eaſily, others not ſo readily receive the malignant tincture of the Peſtilent Air. Thoſe who by reaſon of ill feeding are full of evil humors, and who by reaſon of fulneſs, have their Bloud ſtuffed with firable Sulphur, receive the Peſtilential Poyſon, by the leaſt blaſt of the invenomed Air, eſpecially if fear or ſadneſs happen, which convey inwardly,

and

and lead to the Heart, as it were by a certain attraction, the moſt light darts of the Contagion. On the contrary, thoſe who have their Viſcera clean, and the Maſs of Blood well tempered, and are endued with a ſtrong and fearleſs mind, do not ſo eaſily receive this infection, and ſometimes exterminate itſoon, being received.

Thus much for the beginning and divulgation of the Peſtilence, according to its firſt Fountains, and from thence the ſtream of the infected Air being deduced; it remains for us to ſpeak concerning its propagation by contagion, foraſmuch as it is derived, as it were extraduced from ſome, and ſo to others.

We underſtaud by Contagion, that force or action, by which any Diſtemper reſiding in one Body, excites its like in another. But as this may happen, either immediately by contact, as when any one lying in the ſame Bed with another, taken with the Plague; or mediately, and at a diſtance, as when it happens that the infection is is trans-ferred from one houſe to others remote, or alſo if the Plague come upon any one, after many days or months, perhaps years, handling a Garment, or Houſhold-ſtuff, brought from an infected Houſe; therefore that the Nature of the Contagion, and its diverſe modes may be plainly made known, we will firſt weigh what that is, which ſtreams from an infected Body. Secondly, How it bears it ſelf through the Medium of its paſſage. Thirdly, by what means it begets a Diſtemper like it ſelf, in another Body.

1. That from every Body, although of a more fixt Nature, *Effluvia* of Atoms conſtantly fly away, and run forth, which round about conſtitute as it were a Cloud or Halos, and as it were cloath it, like the down of a Peach, is ſo much received among the more ſound Philoſophers, that nothing can be more. But by how much the more any thing conſiſts of active Particles, by ſo much the more it ſends from it ſelf little Bodies of more remarkable virtue and Energy. Hence the *Effluvia* which fall from Ambers, are able to move other Bodies from their place: Emanations proceed from Sulphureous things, which fill the whole Neighbourhood with Odors. And ſo when the Peſtilential Venom, as hath been already ſaid, is from hence any where fixed, and though in the ſmalleſt Bulk, is of great efficacy and operation, there is a neceſſity that ſome emanations proceed from the Body imbued with it, which refer the Nature or diſpoſition of the ſame Poyſon and Malignity, and diffuſe them on every ſide according to its ſphear of activity. But when theſe little Bodies, which retain the contagion of the Peſtilence, as they ſtream from one Body, are not preſently received by another, we ſhall enquire how they carry themſelves, in reſpect of their paſſage through the Medium.

Where we ſhall preſently meet with a difference in thoſe, from many others, for that the *Effluvia*, which ordinarily evaporate, do not long retain the Nature or Diſpoſition of the Body, from which they flow, but either vaniſh into Air, or being impacted to other Bodies, are aſſimilated to them; but thoſe Particles, which fall from a Peſtilential Infection, are not eaſily ſupped up by the Air, or any other Body, ſo as they may be wholly deſtroyed; but among the various confuſions of Atoms, and the daſhings of other Bodies, they keep themſelves untouched. For this untamed Poyſon remains ſtill the ſame almoſt, and not to be overcome by others, and though it conſiſts of never ſo little heap of Atoms, will not preſently vaniſh; but with its Ferment, imbues the next little Bodies, and ſo acquires new forces, and gains ſtrength by going; from whence it lurks a long while in ſome Neſt, and after a long time, when it aſſaults a convenient Subject, puts forth it ſelf, and imparting the taint of its Poyſon to another, raiſes up again the Diſeaſe of the Peſtilence anew, which ſeemed before to be exploded, and though from the ſmalleſt Seminary, ſprinkles far and near its deadly poyſon.

For the Peſt brings forth ſuch moſt ſure ſigns of its Contagion, that ſome Authors contend, that for this reaſon it only continues among Mortals, and doth never ſpring up anew, but is only conſerved from its Neſt, and carried from thence, from one Region to another. Hiſtories relate, that the Seeds of this have lain aſleep for ſeveral years, in ſome Garment or Bed-cloaths, and that afterwards, they being ſtirred, it hath appeared, and hath ſtirred up anew the Diſeaſe of the Peſtilence, increaſing with a mighty ſlaughter of men. When by reaſon of the Tinder, or cheriſhing Neſt, the Plague is propagated after this manner, at a diſtance, the invenomed little Bodies, which remain in the infection, being moved, preſently leap out, and unfold its Poyſon every way, as it were by a certain irradiation: if that they ſtrike againſt any human body, preſently they lay hold on the Spirits, and are by their Vehicle conveyed inwardly, and then by an eaſie labour, they infect the Blood and Humors, whereſoever flowing in the Veſſels, with their Ferment, and quickly bring to them coagulations and putrefaction. And after this manner, through the moſt ſubtil *Effluvia*, is made as it were a certain tranſmigration of the peſtilential Diſeaſe, even as when a ſhoot being cut off from ſome Tree, and laid up for a time, and afterwards ingrafted to another Trunk, though from the ſmalleſt Bud, it is able to produce a Tree of the ſame kind and nature.

CHAP. XIII.

Of the Plague.

THus far we have diſcourſed of Poyſon in general, alſo of the Peſtilence, its beginning and propagation by Contagion: it now remains, that we explicate the Deſcription of the Plague, its Nature, according to its Accidents and Symptoms, moſt worthy of note; then ſome things ſhall be added which belong to its Cure.

The Plague may be deſcribed after this manner; That it is an Epidemical Diſeaſe, contagious, highly infeſtous to human kind; taking its beginning from an envenomed infection, received firſt by the Air, and then propagated by Contagion; which having hiddenly and largely ſet upon men, cauſes extinctions of the Spirits, coagulations of the Blood, Blaſtings, Mortifications or Deadneſſes of the ſolid parts, and with the appearances of Whelks, Buboes, or Carbuncles, as alſo with the horrid Proviſion of other Symptoms, brings the Sick in danger of Life.

Although the Plague be one kind of Diſeaſe, and its ſpecifical differences, or eſſential are not found, yet by reaſon of the divers kinds of Accidents, which come upon it, ſome diverſities and irregularities of it are obſerved, which ſomething vary the type of the Diſeaſe, though they change not the ſpecies. For firſt this Diſtemper ſometimes is more univerſal, that it rages every where through many Villages and Cities at once; but ſometimes it is circumſcribed in narrower bounds, and only threatens one Region or Tract of Land, Secondly, Sometimes the Plague comes ſimple, and unmixt with other Diſeaſes, wherefore privily, and as it were by ſurprize, almoſt without a Feaver, or vehemency of Symptoms, brings a ſecret killing of the Sick. Sometimes it is complicated, with a number of other Diſeaſes, that the buſineſs is carried with tumult and frequent skirmiſhing between Nature and Death. Thirdly, the degree of Malignity conſtitutes a great difference; for the Plague in ſome places and times is much more mild, that many of the Sick eſcape; ſometimes it is highly mortal, that moſt taken are killed, and that ſcarce one of a hundred recovers.

But becauſe this Diſeaſe hides its weapons, and coming on men unawares, kills them ſuddenly, therefore it ſhall be our work, that by ſome ſigns, as it were Watchmen planted, we may know the clandeſtine coming of this Enemy, although we are not able to foreſee it from afar. Very many ſigns happen, which foretel ſhortly a Plague about to come; to wit, if the Year keeps not its Temper, but has immoderate, and very unſeaſonable exceſſes, either of Heat or Cold, or Drineſs or Wet; if the Small Pox or Meaſles do every where rage; if Boils or Buboes accompany reigning Feavers. Beſides, Aſtrologers are wont, from the Aſpects of the Stars, or Appearances of Comets, to predict the approaching Plague, but this ought rather to be called a vain Conjecture, than a certain foreknowledge. From a preceding Famine, a moſt certain preſage may be taken, of a Plague to follow, as in the Adage, Μετὰ λιμῶ λοιμὸς; the Plague comes with the Famine. For the like Conſtitution of the Year, which for the moſt part, by reaſon of the Corn being blaſted, brings ſcarcity, is apt alſo to produce the Plague; alſo, an evil way of feeding which people in Dearths uſe, eating all unwholſom things, without choice, diſpoſes their bodies to the more eaſie receiving the Infection. Yea, alſo Earthquakes, freſh openings of Caverns and ſecret Vaults, by the gaping of the Ground, by reaſon of the Eruptions of malignant and empoyſoned Airs, often give beginning to the Peſtilence. For indeed, as there is need of great diligence to foreſee, as it were from a Watch-Tower, the approaching Plague, ſo there is no leſs need of care and diligence, to conſider, or take notice of the ſame, being freſh riſen, and the ſhooting of its firſt darts; for oftentimes, being too ſolicitous, we dread vulgar Feavers, if perchance they end in Death, for this Diſeaſe; and ſometimes being too ſecure, contemning the Peſtilence, by reaſon of its Symptoms, like to a common Feaver, we apprehend not our danger, till too late; wherefore, for the more full knowledge of this Diſeaſe, we will ſubjoyn its Signs and Symptoms both Common and Pathognomic, or peculiar, and briefly deſcribe their Cauſes, Means and manner of being done.

Beſides the Signs already delivered, which by a certain demonſtration *a priori*, or beforehand, bring a ſuſpition of the Plague about to come, there are others, the concourſe of which, plainly ſhew its preſence in the ſick Body; of theſe, ſome are common to the Plague, with a Putrid Feaver, ſome are more proper to this Diſtemper. For the impreſſion of the Peſtilence moſt often ſtirs up an effervescency of the Blood, and ſo has frequently a Feaver joyned with it, that among ſome, in the definition of the Plague, it hath the place of a kind of Feaver; wherefore, by reaſon of the ebullition of the Blood, and the hurt brought to the Viſcera, preſently there follows, a growing hot, a ſpontaneous wearineſs, thirſt, a burning of the Præcordia, often great vomitings,

ings, pains of the Heart, Torments of the Inteſtines, a Scurfineſs of the Tongue, or a Blackneſs, a pain of the Head, Watchings, Phrenſie, Palpitation of the Heart, Swooning, and ſudden loſs of Strength; though Feavers are moſt often beſet with theſe kind of Symptoms, yet if at the ſame time the Plague hath ſpred in the Neighbourhood, and a fear of it hath poſſeſſed the minds of men, hence a greater ſuſpition of this Evil is cauſed, eſpecially, becauſe, whilſt the Peſtilence reigns, other Diſeaſes in any one, leave their proper Nature, and change into it: wherefore, if there happens to the Diſtempers but now recited, a Communication of the ſame Sickneſs to many, and a frequency of Burials, that it becomes every where very deadly, and ſpreads largely even by contagion; and if beſides, Buboes, Carbuncles, Spots, or other marks of the Peſtiferous Infection appear, the buſineſs is put without doubt, and we may with no leſs faith denounce it the Peſtilence, than when we ſee an Houſe flaming, with fire breaking through the Rafters, we cry out Fire. But becauſe here is mention made of Buboes, Carbuncles and of other Symptoms (of which we have already ſpoken, where we treated of Putrid Feavers) it remains that we briefly touch the Cauſes of them, and the manner of their being made: They are theſe; A Carbuncle, a Bubo, Whelks, Inflammations, and malignant Puſtles.

Concerning theſe in common, we ſay, that they are all produced of the Blood and Nervous Juice, touched with the peſtiferous Poyſon, and coagulated in parts, in their Circuit, and diſtempered variouſly with Putrefaction; foraſmuch as the Spirits reſiding in either Liquor, eſpecially in the Blood, are no ſooner profligated, by the blaſt of this malignant Diſeaſe, but a coagulation is induced to the remaining Liquor, even as Milk growing ſowr, or when ſome acid Juice is powred to it, wherefore, portions of it being more grievouſly touched with the Poyſon, they ſoon curdle or grow into gobbets, and ſuffer corruption with blackneſs, like Blood out of the Veſſels; from whence, preſently they hinder the motion of the reſt of the Blood in the Veſſels, and in the Heart, and by means of its Ferment, more coagulate it; but whatſoever by congelation grows into curdled gobbets, unleſs it be preſently caſt out of doors, cauſes Death quickly, by reſtraining the Circulation of the Blood; and being thruſt forth outwardly, towards the ſuperficies of the Body, it is ſtopped in its motion, between the narrow Windings of the Veſſels; and being wholly deſtitute either of Spirit, or being ſtruck by a blaſting, produces its Deadneſs, black and blew Spots, and black or purple Marks; or by reaſon of the Salt and Sulphur being exalted by the Peſtilential Ferment, and affecting new things, grow together into tumors of a various kind.

A Carbuncle, or fiery Inflammation, is a fiery Tumor, with moſt ſharp and burning Puſtules round about it, and infeſting the ſick with an acute pain; which ariſing in various places ſeverally, will not be ripened, but creeping more abroad on the ſuperficies, burns the skin, and at length ſhakes off the Lobes or Gobbets of its Corruption, and leaves an hollow Ulcer, as if burnt by an Eſcharotick or burning Plaiſter.

The Generation of Plague-Sores, ſeem to be made after this manner, when poyſonous Infections do ſtrike into the Blood, in its own nature torrid, portions of it congealed, are fixed in the ſuperficies of the Body; and in that place, becauſe the motion of the Blood is a little hindred, a Tumor at firſt ſmall, is induced; which afterwards, by a malignant Ferment, unfolding it ſelf more largely, being leiſurely increaſed, creeps into the neighbouring part: A Suppuration follows not, becauſe the matter being extravaſated, and ſtagnating, is not concocted and digeſted by a gentle heat, but by reaſon of the Particles of the outragious Sulphur, together with the carried forth Salt, being heaped up in theſe Tumors, and becauſe of the ſtagnation, they being preſently looſened from the mixture, a burning is excited, as if a Cautery were affixed to the part: pieces and lobes of skins, eaten as it were from a covered Eſchar, fall off, becauſe the corroſive Venom, impacted in the Muſcles, gnaws not only to the ſuperficies, but thoſe that lie tranſverſe through the whole ſubſtance; wherefore, before all the fleſh is conſumed with the Membranes, in which the eaten Pieces were invalved, ſome piece, as it were cut off from the reſt, falls away. A Carbuncle, oftentimes but one, oftentimes more ariſe: ſometimes they are alone, ſometimes they are accompanied with a Bubo.

A peſtilent Bubo ſprings forth only in glandulous places, into whoſe ſubſtance goes, not only the Blood congealed by the Poyſon, and carried through the Arteries, but the nervous Juice heaped up there, and carried back into the Veins. Becauſe this Tumor happens from leſs torrid Juices, and in part more frigid, therefore it partakes of ſuppuration: for the matter being leiſurely heaped together, when (by reaſon of the ſtagnation) the vital Spirit being departed) it had loſt the form of Blood, it was by a long concoction converted into matter, from the particles of Salt and Sulphur exalted, and reſtrained in the Tumor. But that theſe Tumors only happen in the Glandula's, the reaſon is, not that by the deſtination of Nature, the Neſt or Tinder of the Diſeaſe is carried to theſe parts, but as the particles of the virulent infection, abound every where in the Blood, and nervous Juice, they are more readily gathered together, as in a common Family, and where the Blood being dilated to the extream parts of the Arteries, and is ſo not readily received, and carried back by the Veins, and alſo the alible Juice to be carried back from the Nerves, into the Veins, is depoſed; either of theſe, as it appears clearly, by late obſervations of

Anatomiſts, and by experience, are made or done about the Glandula's; wherefore, when in theſe parts, either humors, being ſtuffed with the peſtilent ſeeds of the Contagion, come together at once, as it were the Neſt of the malignity, becauſe of the virulency here depoſed from either, is blown up.

Whelks, fiery Inflammations, and purple Spots, in reſpect of the Venom, are of the ſame ſtuff as the Tumors but now deſcribed: but in theſe, the product of the virulency conſiſts in a leſſer ſubſtance, yet with greater danger, by reaſon of the ſeeds of the Poyſon being more diſperſed; more ſmall portions of the coagulated Blood being fixed in the skin, conſtitute theſe leſſer appearances, wherefore, out of theſe, ſome being increaſed, are ripened into little itching bliſters; others, by reaſon of a certain blaſting, or deadneſs of the corrupted Blood, grow into black and blew, and purple ſpots.

Although the Plague, by reaſon of its ſudden, ſecret, and very ſwift aſſault upon ſick people, hardly gives time or place for a Prognoſtick, and when this Diſeaſe, by reaſon of the occult manner of hurting, contains in it ſelf nothing that is not ſuſpected, yet there are ſome ſigns that appear in its courſe, by which we are wont to foretel either Life or Death. The buſineſs is then deſperate, if the Diſeaſe paſs preſently into an Epidemical Diſtemper, and makes violent Aſſaults; if that bleeding, or only a ſmall Sweat follows in the beginning of the Diſeaſe, if the Urine be thick and troubled, the Pulſe unequal and weak; if a Convulſion, or a Phrenſie preſently follow: if the Vomits or Stools are blewiſh, black, or highly ſtinking; if the Whelks at firſt contract a redneſs, afterwards a blewneſs; if the Carbuncles are many; if the Buboes at firſt ſwelling up, diſappear; if ſtrength be ſuddenly loſt, the Face horrid, or grows black and blew; if with a ſhivering of the outward parts, there be a heat of the Bowels; eſpecially if theſe, or many of them happen in a Body full of ill humors, or in an unwholſom ſeaſon. On the contrary, the ſick may be bid to be of good chear, if the condition of the Peſtilence be lighter, and leſs deadly; if the the Diſeaſe happens in a robuſt and healthful body, with a ſtrong mind; if Remedies may be timely had, before the Diſeaſe hath poſſeſſed the whole maſs of Blood. Alſo, if with a continuance of ſtrength, high and equal Pulſe, a ſuppuration of the Buboes, and a large profuſion of Matter, with the abſence of more horrid Symptoms, the courſe of the Diſeaſe is performed: In the mean time, although here we may hope all good, yet we are not to be ſecure, becauſe, ſometimes the ſnares of life are laid privily, with the laudable appearance of ſigns, and we ſuffer moſt grievouſly as from a reconciled Enemy, whoſe fierce threatnings we ſeemed to have ſhunned.

Concerning the curing of very many ſickneſſes, the buſineſs is chiefly committed to Nature, to whoſe neceſſity, Phyſick is the Midwife; and the Office and Science of a Phyſician chiefly is buſied in theſe, that occaſions of giving convenient Aids to this labouring be attended; but the Plague hath this peculiar, that its Cure is not at all to be left to Nature, but that it is to be endeavoured any way, by Remedies gathered from Art. Nor are we to be ſolicitous of a more opportune, or as it were a gentler time, but Medecines are moſt quickly to be prepared, and we muſt not ſtay for them ſome hours, no nor minutes: But becauſe, whilſt the Peſtilence reigns, there is no leſs need of care, that the Contagion may be driven far away, than that the Diſeaſe being impreſſed, may be cured; therefore a double task is incumbent on the Phyſician, to wit, that he looks to the prevention of this malignant Diſeaſe, as well as to the Cure. To preſcribe a method for both theſe, had been a work of too much tedioufneſs, and to have given you a Diſh a thouſand times dreſſed by Authors; wherefore, we will only touch lightly here ſome chief Indications, and haſte to other things.

Preventive Cautions either reſpect the Republick, and belong to the Magiſtrate, or private perſons, to whom it ſhould be taught, what is to be done by all men, when the Plague is feared.

The publick Care in the time of the Plague, conſiſts chiefly in theſe, That Divine Worſhip be truly obſerved, that all Neſts of Putrefaction be cut off, that Filths, Dunghils, and all ſtinking things may be removed out of the Streets, and all occaſion of the Contagion diligently avoided, and that an wholſom means of Living be conſtantly obſerved by the Citizens: For which end, the uſe of Fruits, and of other unwholſom things ſhould be interdicted; that poor people, who have not plenty or choice of food, ſhould be provided for at the publick Charge: If ſtill the Peſtilence begins to ſpread, the empoyſoned force of the Air ſhould be corrected as much as may be, which may be beſt done, by the frequent burning of Sulphureous things; the the infected ſhould be ſeparated from the ſound, and the dead Carcaſes and Houſhold-ſtuff ſhould be avoided; and laſtly, that able and fit Phyſitians, and Miniſters be provided for the uſe of the ſound, and neceſſities of the ſick.

The preventive means of a private perſon, is wont to be concluded in theſe three things; *viz.* Diet, Phyſick, and Chirurgery. Diet reſpects the ſix non-natural things, among which, of the greateſt moment are, the Air, and Paſſions of the mind; as to the reſt, *Hippocrates* his Precept may ſuffice, *viz.* Labour, Meat, Drink, Sleep, *Venus* ſhould be taken moderately. The Peſtilent Air ſhould be avoided, by going into ſome other place; , or corrected by the well burning

ing of Sulphureous things, or whilſt we breath it ſhould be cured by fumigations and ſweet ſmells, often carried near the noſtrils. As to the paſſions of the mind, fear and ſadneſs, whilſt the Peſtilence rageth, are as it were another Plague; for in theſe, the ſeeds of the envenomed Contagion, which are placed in the ſuperficies of the Body, as it were on the edge of a Whirlpool, are ſnatched inwardly, by a certain force, and carried to the Heart; wherefore 'tis a moſt excellent Antidote, to be of a chearful and confident Mind. I have known many, who (as *Helmont* was wont to ſay) by fortifying the Archeus, with Wine and Confidence, never uſed any other Poiſon-reſiſting Medecines, and remained without any hurt of the Contagion among the infected; and on the contrary, ſome ſtruck with fear, when they have dwelt far from all Contagion, have drank in the ſeeds of the Peſtilence, as if they were derived from the Stars.

Among the Chirurgical things to be adminiſtred for preſervation ſake, are wont to be commended, the opening of a Vein, Cauteries and Amulets. Where there is a fulneſs with a great ſwelling up of the Blood; or in thoſe who conſtantly, by long cuſtom are wont to be let Blood, it is convenient to open a Vein; for the leſs the Blood grows hot, and is circulated without tumult in the Veſſels, it will be ſo much the longer ere it be contaminated by the peſtiferous Diſeaſe. Iſſues made by Cauteries, are ſo much uſed, almoſt by the ſuffrage of all, for preſervation ſake againſt the Plague, that it is become the moſt common Receipt; for theſe by a common tranſmiſſion poure forth the aſſiduous coming of the ſuperfluous and excrementitious matter; and if that the infections of the Peſtilence be admitted inwardly, they are caſt forth of doors at theſe open ports.

Amulets hung about the Neck, or born on the Wriſts, are believed to have a wonderful force againſt the Peſtilence; of theſe, among ſome of the greateſt eſteem, are ſuch as are made out of Arſnick, Quickſilver, the Powder of Toads, and other Poyſons. That the ſame in this caſe may be profitable, beſides the Obſervations of Phyſicians, this reaſon may ſeem to perſuade ſomething. The *Effluvia*, or Atomical little Bodies, emerging now from theſe Bodies, now reſiding upon theſe, are before affirmed to fly about through the whole Region of the Air; theſe, as they are diverſly figured, ſome of them eaſily cohere with others, but if they ſtrike againſt ſome of another form, they oppoſe and overturn them: hence the particles of the peſtilent infection, which are adverſe to our ſpirits, excellently agree with thoſe little Bodies of Poyſon, placed near, and are readily fixed to them; wherefore the Amulets made of Poyſon, do this, *viz.* They receive the ſeeds of the Peſtilence meeting us, into themſelves, by reaſon of the likeneſs of parts; alſo, by alluring the ſame from our bodies, into their embraces, they in ſome meaſure, free the infected from the infection.

The Medicinal prevention hath a twofold ſcope: Firſt, That the aſſiduous coming of the excrementitious matter or humors be taken away by a gentle purging as often as there is need: Secondly, That by the daily taking the Poyſon-reſiſting Medecines, our Spirits and Body may be fortified againſt the Aſſault of the poyſon; By the former, the Food and Cheriſhers, of which encreaſe putrefaction brought in by the poyſon are drawn away; by the latter, the firſt enkindling of the peſtiferous infection, as it were, a deadly fire is inhibited. Alexipharmies or Medicines contrary to poyſons, ſeem to be helpful againſt the contagion of the Plague, for this twofold Reaſon; both becauſe the Maſs of Blood and Viſcera being filled with the particles of theſe, and alſo the Spirits before poſſeſſed with the ſame, they do not eaſily admit of the company of the impoyſoned infection; alſo, becauſe the Blood being incited by the gentle fury of theſe, is kept from coagulation.

Thus much for preſervation, it follows now, that we ſpeak of the Cure of the Plague. The Doctrine of which, is either general, and comprehends Remedies, which for this end, are taken from Diet, Chirurgery, and Medecine; or ſpecial, which delivers the uſe and Cautions to be exhibited about thoſe Remedies; and by what means we are to oppoſe the Symptoms variouſly ariſing.

Diet comprehends the uſe of the ſix Non-naturals, but the chief care, and medical Cautions, are to be given about Eating; the primary Indications of this, conſiſt not at one and the ſame time together, but ought to be ſupplied by turns, according to the nature of the thing, and the exigency of Nature. In reſpect of the malignity, and of the loſs of ſtrength, Aliments are to be deſired, which greatly cheriſh the Spirits, and bring a more plentiful Nouriſhment: in reſpect of the Feaveriſh Diſtemper, a more ſlender refrigerating Diet, and temperating the Blood, ſeems to be required: the Phyſician muſt regard either, but he may rather intend his Remedies againſt the Malignity, than the Feaver.

The Helps that belong to Chirurgery, are the opening a Vein, which ſeldom and very cautiouſly ought to be uſed in this Diſeaſe, becauſe the Blood being too much exhauſted, and the Veſſels falling down, Sweat is not ſo eaſily procured; inſtead of this, it is better to uſe Cupping, with Scarification; for this and Bliſtring are rightly applied for the drawing forth of the Venom; moreover, againſt Buboes, Inflammations, or malignant Ulcers produced by them, Cataplaſms, Fomentations, Plaiſters, Oyntments, and many other things, to be outwardly applied, are to be ſought for from Chirurgery, in which ſome Poyſons, as the Electric of Poyſon,

are

are preſcribed by ſome to be admixed; wherefore, Preparations of Arſnick, to wit, the Oyl and Balſom of it, are commended by many, in this caſe too of moſt excellent Uſe and Efficacy.

Medecines for the Cure of the Plague, are either Evacuators, or Poyſon-reſiſters: The intention of the former is, that the ſerous Latex in the Blood, and the excrementitious Humors, which abound in the Viſcera, be thruſt forth of doors; and together with them, very many Particles of the envenomed Infection, every where diſperſed in the Body: But theſe are both Vomitories and Purgers, the uſe of which is more rare, and only in the beginning of the Diſeaſe, alſo Diaphoreticks or ſweating Medecines, which at ſometimes may be ſuffered according as there is ſtrength, are to be preſcribed in the Plague; for theſe more fully, and from the whole Body at once evacuate, yea, and by agitating the Blood, defend it from Congelation, and as they move from the Center, ſtill to the Circumference, they drive the empoyſoned Ferment, alſo the Corruptions of the Blood and Humors, far from the Heart, and ſo chaſe the Enemy without the Camp. But Vomits and Purges evacuate leſs univerſally, and by concentrating the malignant matter, oftentimes carry it inwardly, and fix it to the Bowels. But theſe Medecines, whether they operate by purging, or ſweating, ought to be of that kind, which have particles, rather agreeable to the empoyſoned infection, than to our Blood or Spirits; for ſuch a Medicine will paſs through the various windings of our body, with its whole forces and unmixt, and by reaſon of the ſimilitude of either, more certainly takes hold of the virulent Matter of the Diſeaſe, and carries it forth of doors with it ſelf, by the mutual adheſion of the parts, which way provoked Nature leads. Wherefore, Medecines, whether Catharticks, or Sudorificks, are commended before others, which are prepared out of Mercury, Antimony, Gold, Sulphur, Vitriol, Arſenick, and the like; which, when they cannot be ſubjugated by our heat, or maſtered, become the beſt Remedies againſt the poyſon of a Peſtilent Diſeaſe; for theſe do not only potently evacuate ſuperfluous things, but whenas they put forth very ſtrong and untameable particles, and explicate them every where in the Body, diſſipate the Ferments of the Poyſon growing here and there, and hinder them from maturation; and as theſe Remedies, being of themſelves not to be overcome by Nature, are neceſſitated to be carried outwardly through through the open paſſages of the Body, they carry forth of doors with them, whatſoever extraneous or hoſtile thing is met with.

As to Poyſon-reſiſting Medecines, or Alexiterians, which are ſaid to reſiſt the Poyſon of this Diſeaſe, without any ſenſible evacuation, they are (for the moſt part) ſuch whoſe particles are not very much of kin to Nature, ſo as to go into Aliment; nor ſo diverſe, as to provoke to an excretion. The ſame being inwardly taken, and broken into the ſmalleſt pieces, inſpire the Blood, and Juices flowing together in the Veſſels, and Viſcera, with their little Bodies, as with a new Ferment, and by moving the ſame gently, and by keeping them in an equal mixture, defend them from Coagulation and Putrefaction; diſſipate the particles begun to be heaped up, one from another, by the ſame gentle agitation, and hinder them from maturity; and laſtly, by prepoſſeſſing the Blood and Spirits, defend them from the impreſſions of the peſtilent Mark. Among theſe, ſome more ſimple Remedies are commended, as Rue, Scordium, *&c.* But moſt of all by far are eſteemed, thoſe that are compounded; wherefore, Treacle, Mithridate, and Diaſcordium, ſome of which are compoſed of no leſs than fifty ſimples; that it is eſteemed a Crime in Medecines ſo compleat in all numbers, to omit one Plant, or one Dram of them in their Compoſitions; the reaſon perchance is, becauſe very many things being put together, may make a Maſs, whoſe diverſe kinds of particles being exalted, by long digeſtion, may ſtir up the greater Fermentation in our Blood and Humors.

Having after this manner ranked the Remedies, in which we ought to be inſtructed, for the curing of the Plague; now next we ſhould ſpeak of the Method of Cure, *viz.* What firſt, and then what next ſhould be done in order: but that Diſeaſe hath ſo precipitous a courſe, that there is neither place for deliberation, nor is there frequently any Phyſician to be gotten, for fear of the Contagion; wherefore, there is no need here of many preſcripts, or a long ſeries of Indications; this buſineſs is to be quickly performed, and may be comprehended in a few things. Therefore, when the Peſtilence reigning, any one is diſtempered with the Contagion of this Diſeaſe, the help of the Omnipotent God being requeſted by Prayers, preſently Remedies are to be flown to. If the Plague happens in a Body not throughly purged, and prone to Vomiting, preſently let a Vomit be taken, whoſe operation being finiſhed, immediately let a Sweat be provoked, by taking Diaphoreticks, and the ſame continued as ſtrength can bear it, and afterwards be often repeated. Beſides, let Alexipharmicks or Poyſon-reſiſters be uſed almoſt every moment, until by the eruption of Whelks, Inflammations, or Buboes, all the Venom be wholly driven forth of doors; but in the mean time, proper and reſpective Remedies are to be oppoſed to the moſt urging Symptoms; but eſpecially fit helps are to be ſought from Chirurgery, for the Cure of the Buboes, and Plague-Sores: the whole weight of this buſineſs leans on theſe two Intentions, that the peſtiferous Poyſon may be every way expelled from within, and then, that the Recourſe of what is driven forth, be with equal diligence prevented.

Con-

Concerning the Plague, we cannot ſo readily write Examples, and Hiſtories of ſick perſons, with exact Diaries of the Symptoms; becauſe theſe kind of Sickneſſes came not every year, neither when they ſpread, is it lawful for every Phyſician that takes care of his own health, frequently to viſit the ſick, or to ſtay long with them, whereby he may denote all Accidents, and diligently conſider the reaſons of them; which Task however, the renowned *Diemerbrochius* did ſo firmly perſiſt in, that after him, others may lawfully be ſuperſeded from this Work: when ſome times paſt, in this City, *viz.* 1645. the Plague (though not great) had ſpred, Dr. *Henry Sayer*, a very Learned Phyſician, and happy in his Practice, many others refuſing this Province, boldly viſited all the ſick, poor, as well as rich, daily adminiſtred to them Phyſick, and handled with his own hands, their Buboes, and virulent Ulcers, and ſo cured very many ſick, by his ſedulous, though dangerous Labour. That he might fortifie himſelf againſt the Contagion, before he went into the infected Houſes, he was wont only to drink a large draught of Sack, and then his perambulation about the Borders of Death, and the very Jaws of the Grave being finiſhed, to repeat the ſame Antidote: After he had in this City, as if inviolable as to the Plague, a long while taken care of the Affairs of the Sick without any hurt, he was ſent for to *Wallingford*-Caſtle, where this Diſeaſe cruelly raged, as another *Æſculapius*, by the Governour of the Place: But there being ſo bold, as to lie in the ſame Bed, with a certain Captain (his intimate Companion) who was taken with the Plague, he quickly received the Contagion of the ſame Diſeaſe; nor were the Arts then profitable to the Maſter, which had been helpful to ſo many others, but there with great ſorrow of the Inhabitants, nor without great loſs to the Medical Science, he died of that Diſeaſe. As to others, diſtempered by the Peſtilence, he was wont to order this kind of method of healing, if he was ſent for before the Buboes or Whelks appeared outwardly, for the moſt part he gave a Vomit, the preſcriptions of which were the Infuſion of *Crocus Metallorum*, ſometimes with white, and ſometimes with *Roman Vitriol*: The Vomiting being ended, he commanded them preſently to be put into a Sweat by the taking of Diaphoreticks; and thence, ſome intervals being granted, for the recovery of ſtrength, the ſweating to be continued to the declination of the Diſeaſe: but if he were ſent for to the ſick, after the appearances of the Marks, the Vomiting being let alone, he inſiſted only upon Sudorificks.

CHAP. XIV.

Of Peſtilential and Malignant Feavers in Specie, *and of others Epidemical.*

AFter having having unfolded the Nature of the Plague, by the order of our Tract, we ought to proceed to the Diſeaſes which ſeem to be neareſt like its Nature; which chiefly are Feavers, called Peſtilent and Malignant; for it is commonly noted, that Feavers ſometimes reign popularly, which for the vehemency of Symptoms, the great ſlaughter of the Sick, and the great force of Contagion, ſcarce give place to the Peſtilence; which however, becauſe they imitate the Type of putrid Feavers, and do not ſo certainly kill the ſick, as the Plague, or ſo certainly infect others, they deſerve the name not of the Plague, but by a more minute appellation of a Peſtilential Feaver: Beſides theſe, there are Feavers of another kind, the pernicioufneſs and contagion of which appear more remiſs, yet becauſe they are infeſtous, beyond the force of putrid Feavers, and ſeem to contain in themſelves in a manner, the τὸ Θεῖον or Hand of God of *Hippocrates*, are yet by a more ſoft Appellation, called Malignant Feavers.

Thoſe Feavers differ both from the Peſt, and from one another according to the degree, and vehemency of Contagion and deadlineſs; as the Plague is a Diſeaſe highly contagious, and deadly to humane kind; 'tis the Peſtilent Feaver, which commonly ſpreads with a leſſer diffuſion of its infection, and frequency of Burials. When the infection is only ſuſpected, and the Criſis happens beyond the Event of vulgar Feavers, only not to be truſted, or leſs ſafe, it is eſteemed for a Malignant Feaver, They are yet more fully deſcribed thus;

When the Feaver commonly ſpreads abroad, which for the variety of Symptoms, puts on the likeneſs of the putrid Feaver ſo called, to wit, when there are preſent, Thirſt, Burning, Wearineſs, Anxiety, roughneſs of the Tongue, Watchings, Phrenſie, Vomiting, want of Appetite, Syncopy, Swooning, Heart-pains, and a concourſe of other moſt terrible Accidents; if there happen beſides, Spots either like to the little Flea-bites, or broad ones, like black and blew ſtrokes, and livid, we eſteem this Diſeaſe of an evil Nature. If beſides theſe, it is not cured after

after the wonted manner of Feavers, but that the ſtrength of the Sick is caſt down, without any manifeſt cauſe, and that Death comes often unlooked for, and unſuſpected, againſt the Prognoſtick of the Phyſician, there is yet a greater cauſe of ſuſpition of malignity: But if it kills very many of the ſick, and that thoſe who converſe with the ſick, contract the evil of the ſame Diſeaſe, that the ſame Diſeaſe ſpreads through all the Villages or Cities, it may be ſaid to be more than malignant, a peſtilential Feaver; which is yet fully proved, if it rages in very many ordinarily with a certain common ſymptom, as when a Squinancy, Dyſentery or deadly Sweat, ſuch as in times paſt ſpred in *England*, accompany theſe ſort of Feavers.

If that a Feaver ariſes, which diſtempers many living in the ſame Region together, almoſt after the ſame manner, which notwithſtanding obſerves the Laws of a common putrid Feaver in its courſe, and is cured almoſt after the ſame manner, this is not ſaid to be Peſtilent, but only a Malignant Feaver; unleſs that in ſome labouring with a remarkable Cacochimy, or fulneſs of ill humors, the appearances of Buboes, or of ſpots, ſometimes with a deadly Criſis, and a Contagion creeping upon others, betray ſome ſigns of Malignity.

If it be demanded, to which Claſs of the aforeſaid Feavers theſe ſort of Peſtilential and Malignant Feavers ought to be placed, we aſcribe them only to the rank of continual Feavers; we diſchage or acquit intermitting Feavers, becauſe by intervals they grant ſuch firm Truces to Nature, and then they regularly and exactly obſerve their periods, which does not conſiſt with an envenomed diſpoſition. Alſo we except Hectick Feavers from malignity, beauſe otherwiſe their mortality would not be ſo long delayed, but that partaking of poyſon, they would kill ſooner: among continual Feavers, although we affirm, that the ſimple ſynochal Feavers are not free, yet they are rarely touched with this evil; but moſt of all, the Feaver which ſhews the notes of Peſtility or Malignity, is of that ſort, which reſembles the figure of the putrid Feaver ſo called: for when in theſe Feavers, beſides the appearances of virulency, we perceive a continual growing hot of the Blood, which paſſes through the courſes or ſtadia of beginning, increaſe, ſtanding and declination, as in putrid Feavers, we deſervedly affirm here, the ſulphureous part of the Blood to be heated and enkindled, and by its burning to have brought in the Feaver; wherefore in theſe kind of Feavers two things are eſpecially to be noted, the growing hot of the Blood, and the malignity joyned with it, of which now this, now that is the greater: alſo, in both there is a great latitude, and very many degrees of its intenſion or heat, according to which the Feaver becomes more or leſs acute or malignant.

The growing hot of the Blood is performed after the ſame manner, as is already ſaid concerning Putrid Feavers, to wit, the ſulphureous part of the Blood growing hot above meaſure, as it were takes fire by its fervor; in the time of its burning, it accumulates a great quantity of aduſt matter, upon whoſe ſubaction and ſecluſion, depend the State and Criſis after the wonted manner of Feavers; but beſides theſe, the Blood being infected with a certain venomous taint, in the burning it begins by reaſon of the malignant ferment, to be coagulated into parts, and to putrifie: wherefore beſides the uſual Symptoms of the common Feaver, by reaſon of ſome congealed portions of the Blood, follow either deadly Diſtempers, Swooning, a Dejection of the Spirits, alſo appearances of Spots and Marks; beſides venomous *Effluvia*, which depart from the ſick, that are able to raiſe up the like Diſtemper in others, by the force of their Contagion; wherefore by reaſon of its perniciouſneſs and contagion, and their various degrees, it is called either a Peſtilent or Malignant Feaver.

Alſo whilſt the Blood growing hot, is infected with a venomous and malignant ferment, not only proper coagulations of its maſs, with a diſpoſition to putrefaction, are induced; but alſo the Nervous Liquor, eaſily contracts the taint of this, from whence it being made improportionate to the Brain and Regiment of the Animal Spirits, ſtirs up great irregularities in them: wherefore upon theſe ſort of Feavers, come not only ſpots and whelks, but moſt often a Delirium, Phrenſie, Sleepineſs, Tremblings of the Limbs, Cramps, and Convulſive Motions; I have often obſerved, that in ſome certain years, Malignant Feavers have increaſed, which have ſhewn their virulency, without the appearances of Marks, chiefly about the Nervous ſtock; becauſe in ſome, preſently after the beginning, has followed a ſleepineſs, with a mighty heavineſs of the Head, in others, ſtrong Watchings, a perturbation of Mind, with Trembling and Convulſive Motions, but in moſt, either none, or only an uncertain Criſis, and inſtead of it, a tranſlation of the Feaveriſh Matter to the Brain; beſides it is obſerved, that theſe Feavers creep upon others Contagion, and that very many are killed by them, that therefore they do deſerve to be called Malignant.

But theſe kind of Feavers are ſometimes firſt begun from a venomous infection, and the Blood being touched with the Particles of the Venom, conceives of it ſelf an Effervеſcency, and is enkindled; as when from a Contagion or Malignant Air being inſpired, any one hath fallen into a Malignant Feaver, without any evident cauſe or prediſpoſition: But ſometimes the Feaveriſh Diſtemper is induced from a proper Cauſe, and then the Seeds of the Malignity, either lying hid within the Body, exert themſelves in the effervent Blood, or they come from another place by the contaminated Air, as it were the Food of the Flame before enkindled; for it appears by frequent

frequent obſervation in the time in which an Epidemical Feaver ſpreads, that others being any way ariſen, turn into it.

Malignant Feavers, as alſo Peſtilential, for the moſt part are popular, and invade many at once; but ſometimes they are private, and not ordinary, ſo that perhaps only one or two are taken in the whole Region; in ſuch a caſe it is to be ſuſpected that they come not from a malignant Air, or Epidemical cauſe, but from a morbous proviſion of the Body; for I have often obſerved that when in the Spring or Autumn, a Feaver ſufficiently common, hath ſpred in ſome City or Town, of which very many have died, perhaps ſome one on whom an evil prediſpoſition and a more ſtrong evident cauſe, hath brought the Feaver, hath lain by it, with more horrid Symptoms, and great notes of malignity: in which caſe that malignity is not to be called common to the Feaver, but not ordinary and accidental only.

Although the greateſt reaſon of the difference, by which theſe kind of Feavers are diſtinguiſhed from one another, and from other Feavers, conſiſts in their deadlineſs and contagion; yet ſometimes they are noted with a certain peculiar Symptom, from which they take for that time, both the note of malignity, and the appellation of the name: hence in ſome years an Epidemical Feaver reigns, which induces to moſt of the Sick a Squinancy, another time an Inflammation of the Lungs, a Pleuriſie, Dyſentery, or ſome other Diſtemper, and that oftentimes moſt dangerous, and contagious; ſo the ſeeds of Diſeaſes, not only derived from the Parents by traduction, excite their fruits as it were by a certain deſignation, in the ſame part or member; but alſo thoſe received from an infection commonly ſpreading, produce in all, a diſtemper of the ſame mode and figure; which yet I think to happen, not becauſe the ſeeds of the venomous Infection, reſpect either this or that Region of the Body, with a certain peculiar Virtue; but theſe ſo affect the Maſs of Blood, by a like manner in all, that there is a neceſſity, for the ſake of waſhing away this ſtain, that a Criſis be attempted after the ſame manner in all. For when, without malignity, the Bloud, by coagulation, or perhaps other Cauſes, is apt to be extravaſated, the uſual places, in which portions of the ſame being extravaſated, are wont to be fixed, are the Throat, Pleura, Lungs, and Inteſtines; wherefore, 'tis no wonder, when from a malignant cauſe, the congelation of the Bloud, and for that reaſon an extravaſation is induced, if the Diſeaſe is neſted in the accuſtomed cheriſhing place of Nature.

Concerning the Cauſes of theſe kind of Feavers, there is not much buſineſs; they are for the moſt part deduced, in reſpect of the malignity, from the vicious conſtitution of the Air; in reſpect of the Feaveriſh heat, from the morbous proviſion of the Body; either of theſe are eaſily made clear, by what hath been already ſaid concerning a putrid Feaver, and the Cauſes of the Peſtilence: If the malignity be ſtronger than the Feaver, and hath induced it, the impreſſion of it is to be imputed to the inſpired Air, or to a contagion received from others, if the Feaver be firſt, its inkindling is aſcribed to tranſpiration being hindred, to a Surfeit, or to ſome other of the evident Cauſes above enumerated.

As to the Signs, beſides Contagion and Deſtruction, theſe ſhew the malignity of the Feaver, a ſudden loſs of ſtrength, a weak and unequal Pulſe, and evil affection of the Brain and Nervous parts, being ſuddenly induced, cruel Vomitings, Blackneſs of the Tongue, a ſuffuſion of Darkneſs through the whole Body, but chiefly the appearance of Spots, Buboes, and of other Marks.

For the Cure of Feavers, both Peſtilential and Malignant, there is greater need of Judgment and Circumſpection, than in any others whatſoever: For when there are two primary Indications, to wit, the Malignity, and the Feaveriſh Intemperance, and when one can ſcarcely provide for the one, without detriment to the other, it is not eaſily to be diſcerned, which ſhould firſt be helped, or ſooneſt regarded. In reſpect of the Feaver, Purging, opening a Vein, and cooling things do chiefly help; but whilſt theſe are performed, the Malignity, for the moſt part is increaſed, and being neglected, ſpreads abroad more largely its Poiſon; againſt the Malignity, Poyſon-reſiſting Cordials, and Diaphoreticks are required, but theſe extreamly heighten the Feaver, they more ſhake the Bloud and Spirits before inkindled, as it were with the blaſt of Bellows, and force all as it were into a Flame; wherefore, here is great need of Skill, that theſe things be rightly ordered in themſelves, and where there is moſt of danger appearing, thence the curative intentions are to be more immediately deſigned; but ſo, as whilſt one is conſulted about, the other be not neglected. But in theſe Caſes, beſides the private Judgment of every Phyſitian, experience may ſupply the chief means of healing; for whenas theſe Feavers firſt ſpread, every one almoſt tries ſeveral Remedies, and by the ſucceſs of them collated together, it may be eaſily reckoned, what kind of Method is to be relied on, till at laſt, by a frequent trial, or the footſteps of thoſe paſſing before, there is made as it were a high and broad Road, for the curing of theſe ſorts of Diſtempers, bounded both with various obſervations and warnings.

Beſides theſe ſort of Feavers, which ſpread on many at once, and by reaſon of the Contagion, Deadlineſs, and conſpicuous Notes of Virulency, deſerve to be called Peſtilent or Malignant; there are ſome others, Epidemical or Popular, which almoſt every Year, either in the Spring or Autumn rage in ſome Countries; of which the Inhabitants for the moſt part of them are wont to be ſick, and not few, eſpecially of the Elder, to die: In which notwithſtanding, no ſigns of Peſtilence or Malignity appear, neither does the Diſeaſe ſeem to ſpread, from one and ſo to another, ſo much by contagion, as to lay hold on many, by reaſon of a prediſpoſition, impreſſed almoſt on all. But theſe kind of Diſtempers depend chiefly upon the foregoing conſtitution of the Year: for if the ſeaſon going before was very intemperate, by reaſon of exceſs of cold or heat, of drineſs or humidity, and ſo had continued for a long time, it changes our Blood very much from its due temperature, whereby it is apt afterwards to conceive Feaveriſh Efferveſcencies; and from hence a Feaver, now of this Type or Figure, now of that is produced; which preſently becomes Epidemical, becauſe it draws its beginning from a common cauſe, wherewith the bodies of all are in a manner affected: But ſuch Feavers, foraſmuch as they depend upon the Blood having gotten a diſpoſition, now ſharp, now auſtere, or of ſome other kind, by reaſon of the temper of the Year, for the moſt part are of the rank of intermitting Feavers; yet by a proper proviſion of Symptoms, they are wont to be noted according to the peculiar conſtitution of every Year. Theſe are not able to be comprehended under a certain common Rule, or formal Reaſon, which may quadrat to the Nature of each of theſe; becauſe they vary every year according to their ſeveral Accidents. However, we will give you the deſcriptions of theſe kind of Feavers, ſpreading of late years in this Region, had at that time, for ſome ſpecimen of the reſt, and add it for a concluſion at the end of this Tract.

There yet remains to be aſcribed to the rank of Malignant Feavers, ſome other private Feavers, and participating of no contagion; of which ſort chiefly are thoſe which are wont to happen to Child-bearing Women, by reaſon of difficult and hard Labour, or by reaſon of the ſtoppage of their Courſes. Indeed it ſufficiently appears by common obſervation, that theſe are very dangerous, and often mortal: for if by the parts of the Womb being hurt, or by Cold being admitted, or perhaps by any other cauſe, the Courſes are ſtopped, and the Humor which ought to be thruſt forth, ſhall be confuſed with the Maſs of Blood, it moſt wickedly infects it, as it were with a certain venomous mixture; that by that means, preſently a Feaver is excited, which with an evil proviſion of Symptoms, is very much beſet, *viz.* with heat and cruel Thirſt, Vomiting, pain of the Heart, and Watchings, and for the moſt part obtains, either no Criſis, or a very difficult one; becauſe, unleſs the wonted way of the flux of the Courſes, may be at length reſtored, it is wont, after the heat of the Blood hath been continued for ſome days, to communicate the evil to the Brain and Nervous Stock; from whence, by and by, a Delirium, Phrenſie, Convulſions, and other moſt wicked Diſtempers, are moſt often induced, which do not ſeldom end in Death: but theſe ſort of Feavers deſerve a peculiar conſideration, which we have more fully determined to ſhew hereafter in a particular Diſcourſe concerning this buſineſs; in the mean time, we will undertake to propoſe ſome Inſtances or Examples of the Feavers, but now delivered, *viz.* of the Peſtilent, and Malignant.

The Peſtilent Feaver, of late years, hath more rarely ſpred in theſe Regions, than the Plague it ſelf: of the only one of this kind, which fell under our obſervation, I will give you a brief Deſcription. In the Year 1643. when in the coming on of the Spring, the Earl of *Eſſex* beſieged *Reading*, being held for the King, in both Armies there began a Diſeaſe to ariſe very Epidemical; however, they perſiſting in that work, till the beſieged were forced to ſurrender, this Diſeaſe grew ſo grievous; that in a ſhort time after, either ſide left off, and from that time, for many Months, fought not with the Enemy, but with the Diſeaſe; as if there had not been leiſure to turn aſide to another kind of Death, this deadly Diſeaſe increaſing, they being already overthrown by Fate, and as it were falling down before this one Death. *Eſſex*'s Camp moving to the *Thames*, pitched in the places adjacent, where he ſhortly loſt a great part of his men; but the King returned to *Oxford*, where at firſt, the Souldiers being diſpoſed in the open Fields, then afterwards among the Towns and Villages, ſuffered not much leſs; For his Foot (which it chiefly invaded) being pack'd together in cloſe Houſes, when they had filled all things with filthineſs, and unwholſom naſtineſs, and ſtinking Odors (that the very Air ſeemed to be infected) they fell ſick by Troops, and as it were by Squadrons. At length the Feaver, now more than a Camp-Feaver, invaded the unarmed and peaceable Troops, to wit, the Entertainers of the Souldiers, and generally all others, yet at firſt (the Diſeaſe being yet but lightly inflicted) though beſet with an heavy and long languiſhment, however many eſcaped. About the Summer Solſtice, this Feaver began alſo to increaſe with worſe proviſion of Symptoms, and to lay hold on the Husbandmen, and others inhabiting the Country. Then afterwards ſpred through our City, and all the Country round, for at leaſt ten Miles about. In the mean time, they who dwelt far from us, in other Counties, remained free from hurt, being as it were without the ſphere of the Contagion. But here this Diſeaſe became ſo Epidemical, that a great part of the people was killed by it; and aſſoon as it had entred an houſe, it run through the ſame,

that

that there was ſcarce one left well to adminiſter to the Sick; Strangers, or ſuch as were ſent for to help the ſick, were preſently taken with the Diſeaſe; that at length, for fear of the Contagion, thoſe who were ſick of this Feaver, were avoided by thoſe who were well, almoſt as much, as if they had been ſick of the Plague.

Nor indeed, did there a leſs Mortality, or ſlaughter of men accompany this Diſeaſe; becauſe Cachectick and Phthiſical old men, or otherwiſe unhealthful, were killed by it; alſo not few of Children, young men, and thoſe of a more mature and robuſt age. I remember in ſom[a] Villages, that almoſt all the old men died this year, that there were any left who were abl[e] to defend the Manners and Priviledges of the Pariſh, by the more anciently received Tradi[e]tions.

When this Feaver firſt began, it was ſomething like the Figure of a putrid Synochus; but it was harder to be cured: and when it ſeemed to be helped by a Sweat or Looſneſs, preſently it was wont to be renewed again; but for the moſt part, after the deflagration of the Blood, continued for ſix or ſeven days, this remitting, and inſtead of a Criſis, the aduſt matter being tranſlated to the Brain, the Sick for a long time keeping their Beds with raging ſometimes, but more often with a ſtupefaction, with great Weakneſs, and ſometimes with Convulſive Motions, ſcarcely eſcaped at laſt. About the middle of the Summer, beſides the Contagion and frequent Burials, this Diſeaſe betrayed its Malignity, and Peſtilential force in open Signs, *viz.* by the eruption of Whelks and Spots; becauſe about this time in many there appeared without any great burning of the Feaver, an unequal, weak, and very much diſordered Pulſe; alſo without a manifeſt expence of Spirits, their ſtrength preſently became languiſhing, and very much dejected: In others, Sick after the ſame manner, appeared little Bliſters or Meaſles, now ſmall and red, now broad and livid: in many, Buboes (as in the Plague) about the Glandula's: of theſe ſome died ſilently and unforeſeen, without any great ſtrugling of the Spirits, or Feaveriſh Burning excited in the Blood: in the mean time others, by and by becoming furibundous, whilſt they lived, ſuffered moſt horrid Diſtractions of the Animal Spirits. Thoſe about to eſcape from this Diſeaſe, without any laudable Criſis (unleſs they were the ſooner freed by a Sweat provoked by Art) the Brain, and nervous ſtock becoming diſtempered, at length, with a benummedneſs of the Senſes, Tremblings, Vertigo, Debility of Members, and Convulſive Motions, did not grow well but of a long time after. During the Dog-days, this Diſeaſe being ſtill infeſtous, began to be handled not as a Feaver, but as a leſſer Plague, and to be overcome only by Poyſon-reſiſting Remedies; letting of Blood, was believed to be fatal to this: Vomits and Purges, ſometimes though not often, were made uſe of, but the chiefeſt means of Cure, were accounted to be procured by Alexiteriums, and timely Sweat. For this end, beſides the Preſcripts of Phyſicians, to be had at the Apothecaries, ſome Empirical Remedies deſerved no ſmall praiſe; then firſt of all, the Pouder of the Counteſs of *Kent*, began to be of great eſteem in this Country; alſo of no leſs note was another Pouder, of the colour of Aſhes, which a certain Courtier ſtaying by chance in this City, gave to many with good ſucceſs; and to others approving of the uſe of it, he ſold it at a great price; the ſick were wont having taken half a dram of this, in any Liquor, to fall into a moſt plentiful Sweat, and ſo to be freed from the virulency of the Diſeaſe; That Diaphoretick (whoſe Preparation I afterwards learnt from the Cozen German of the Author) was only the Pouder of Toads, purged throughly with Salt, and then waſhed in the beſt Wine, and lightly Calcined in an earthen Pot. The Autumn coming on, this Diſeaſe by degrees remitted its wonted fierceneſs, that fewer grew ſick of it, and of them many grew well; till the approach of the Winter, when this Feaver almoſt wholly vaniſhed, and Health was rendred to this City, and the Country round about fully and wholly.

Thus you have ſeen the Beginning, Progreſs, and End of this Feaver, at firſt only a Camp-Feaver, but at length became Peſtilential and Epidemical. That at firſt the Diſeaſe began in the Souldiers Camp, may ſeem to be imputed not only to their Naſtineſs and ſtinking Smells, but in ſome ſort to a common Vice of the Air, for as theſe Feavers come not every year, their Original may be aſcribed, partly to the peculiar Conſtitution of the Year; becauſe by that means a more light intemperance of the Air being contracted, though it did not affect the more healthful Inhabitants; yet in the Army, where evident Cauſes, *viz.* Errors in the ſix non-naturals, very much happen to the general procatartick Cauſe, there is a neceſſity for theſe kind of Sicknelſes eaſily to be excited. For the conſtitution of this year, was in the Spring very moiſt, and ſlabbery, almoſt with continual ſhours, to which a more hot Summer ſucceeding, and the infection of the Feaveriſh Contagion here firſt increaſing, ſtill grew worſe, and diſpoſed all Bodies the more for the receiving it; wherefore, that this Diſeaſe was almoſt proper to this Region, and at this time Epidemical, the ſeed of it ought to be aſcribed to its firſt riſing from the Army, being quartered round about. But foraſmuch as it afterwards being made Peſtilential, and very Epidemical, it infected moſt of the People living here, and killed not a few, the reaſon was, the evil affection of the Air; which becauſe of the intemperance of the year, being unwholſom, beſides by the continual breathing forth of ſtinking Vapors from the Souldiers Camp, and the quarters of the Sick, it became at laſt ſo vicious, that the infection of the Feaver, being diſperſed in it,

was greatly exalted, and aroſe almoſt to the virulency of the Plague. *Diemerbrochius* relates from the like Camp-Feaver, ariſing in the Summer at *Spires*, afterwards another Malignant and Peſtilential, and then the Plague it ſelf to have accrued. Alſo, it was a ſign that this Feaver of ours, became at laſt equal to the Plague it ſelf, beſides the great force of the Contagion, and the frequency of Burials, moſt wicked Diſtempers of the Blood, and nervous Liquor, being brought preſently upon all, by it: becauſe, ſtrength being ſuddenly overthrown, the weak intermitting Pulſe, the creeping forth of Meaſly Bliſters, the eruption of Buboes, argued the Coagulation, and corruptive diſpoſition of the Blood: beſides, the Delirium, Madneſs, Phrenſie, Stupefaction, Sleepineſs, Vertigo, Tremblings, Convulſive Motions, and divers other Diſtempers of the Head, ſhewed the great hurt of the Brain, and nervous Stock.

That the Figure or Idea of this malignant Feaver, may be painted to the Life, very many Obſervations or Hiſtories of ſick people are eaſily to be had; of the many Examples of this Diſeaſe, I ſhall only mention a few, which hapned ſome years ſince in the Houſe of a venerable man, and as with a mournful ſlaughter, ſo not without ſome admiration.

About the Winter Solſtice, in the Year 1653. a Youth of about ſeven years old, without any manifeſt cauſe, found himſelf ill, being troubled with a pain in his Head, Sleepineſs, and mighty Stupefaction; with it he had a Feaver, though not ſtrong, with an ordinary burning, which grew more grievous, only by wandring fits, ſometimes once, ſometimes twice in twenty four hours ſpace: preſently from the beginning, he ſlept almoſt continually; alſo he was wont in his ſleep to cry out, to talk idly, to leap often out of his Bed; being awakened, and ſometimes of his own accord awaking, he preſently came to himſelf, and conſtantly called for drink; his Urine was red, and full of Contents, his Pulſe equal, and ſtrong enough; in his Wriſts appeared light contractures of the Tendons, and in his Neck, and other parts of his Body, ſome red Spots like Flea-bites. At the firſt, was ordered a light Purgation, and a frequent taking down of the Belly, by the uſe of Clyſters; he daily took Cordial Juleps, with Poyſon-reſiſters; Veſicatories or bliſtering Plaiſters were applied to his Neck, and other Plaiſters to the Soles of his feet: on the ſixth day, a little Blood ſtreamed from his Noſtrils; on the ſeventh, without any manifeſt through Criſis, the Feaver very much abated, the heat ſo gentle as to be perceived only by the Touch; alſo the Urine pale, thin, and without any ſediment, yet he was much more grievouſly troubled with ſleepineſs, and a ſtupefaction of the Head, ſo that his Urine, and the Excrements of his Belly came away involuntarily; however, being called upon, he knew the ſtanders by, and anſwered to their Queſtions: Theſe Diſtempers, notwithſtanding the Remedies, every day grew worſe: About the fourteenth day, the ſick Youth became ſo ſtupid, as neitherto be able to underſtand, nor to ſpeak, yet he ſwallowed ſtill what was put into his Mouth, though unknowingly, and his Pulſe was laudable enough: About this time, he fell into a Flux, excited of it ſelf by Nature for four days, which at laſt ceaſing, a whitiſh Cruſt or Scurf, and as it were Chalky, began to ſpread over the whole Cavity of his Mouth and Throat, which being often in a day wiped away, new preſently broke forth: when he had thus for four days more been ſick, he became better in his Intellect and Senſe, ſo that he was able to know his Parents and Friends, to take notice of their words, and to do ſomething as he was bid; but as his ſenſitive Faculty began to be reſtored, ſo he began to grow worſe as to his Speech and the Organs of ſwallowing; without doubt the matter being fallen from the Brain, into the beginnings of the Nerves, a Palſie in the Tongue and Throat had ſucceeded to the heavineſs and ſtupefaction: which Diſtemper in a ſhort time ſo increaſed, that afterwards the ſick perſon could not ſwallow at all, but that what he took in at the Mouth, preſently flowed back again, neither could any thing go down into the Stomach; when beſides the cruelty of the Diſeaſe, there was danger leſt he ſhould be killed by Famine, an Inſtrument was prepared of a Pin of Chalk, put into a little pliant Wand, and on the top of it a little tuft of Silk made fit; and this being thruſt down his Throat, opened the cloſing for a time, whereby the Food taken in, was ſuffered to paſs; after the uſe of this for a day or two, he was able to ſwallow again, and afterwards to take his Food well enough; and within a few days, he began to ſpeak, to diſcern any thing, and becoming wonderful hungry, to ask for, all day long, all ſorts of Food, and greedily to devour whatever was brought to him. In the mean time, by reaſon of his long Sickneſs, and the nervous parts being grievouſly hurt, he was grown ſo lean, that the Bones ſcarce ſticking to the Skin, he repreſented exactly a living Skeleton. But afterwards, by the ſedulous, indefatigable, and prudent Care of the Mother about his Diet, he recovered perfect Health, and is yet living, and well.

When this Child had hardly arrived to the height of his Sickneſs, his Brother, elder about two years, on the Ides of *January*, was taken almoſt after the ſame manner: At firſt he was troubled with a Torpor and heavineſs of the Head, then growing Feaveriſh, with a ſleepineſs and ſtupidity; he began to talk idly in his Sleep, then being awake hardly to come to himſelf: after four or five days, theſe Symptoms grew more grievous; he was able to underſtand little, nor ſcarce to ſpeak articulately, and not without ſtammering. His Urine was thick, cloudy, without Hypoſtaſis, or ſetling of the Contents: There appeared, as in his Brother, red ſpots, ſmall,

ſmall, like Flea-Bites: his Excrements both of his Belly and Bladder, came away involuntarily: but his Pulſe was yet ſtrong and equal; his Hypochondria were ſtretched out, and inflated with a tumor of the Abdomen; about the eighth day, he had a ſmall ſtream of Blood: on the eleventh day of his Sickneſs, he fell into a Diarrhœa, by which, in the ſpace of five hours, he caſt forth ſeven times, bilous, thin, and highly ſtinking ſtuff, from whence there was ſome hope of his amendment; but the next day after, the flux of his Belly ceaſing, pains and torments cruelly infeſted his Belly, that crying out and moaning night and day, he ſent forth moſt heavy complaints; his Hypochondria and Abdomen were tumid like a Tympany, and mightily diſtented; when he could not receive any thing of eaſe, from no Remedies, the moſt exquiſite Skill of many Phyſicians being tried, on the fourteenth day he died Convulſive, in theſe Torments.

A little after his Death, *viz.* on the thirteenth of *February*, his Brother, elder than him, about eleven years old, a Youth of great hopes, began to be Feaveriſh; and as the others, with a torpor and heavineſs of his Head, though leſs ſtrongly affected; but the heat in the Blood was greater, which was of a more hot temperament, and greater perturbation appeared, that for the firſt ſix days, beſides heat and thirſt, he was troubled with a continual endeavour of excretion, now by Sweat, now by Stool. His Urine was red and troubled; ſome red Spots, as in the reſt broke forth; on the ſeventh day he had a bleeding about five Ounces, which ceaſing, a great benummedneſs ſucceeded, that for all that day and the night following, he could ſcarce lift up his Eyes: On the eighth day, a moſt plentiful bleeding followed again at the Noſe, that there was danger, leſt he ſhould have loſt his Life, together with his Blood; the Blood ſprang ſo copiouſly from his left Noſtril, that being received in a Baſon, it made little Bladders or Bubbles by its fall: when he had loſt above two pound of Blood, and being taken with a cold Sweat, began to loſe his ſtrength, Remedies were at length adminiſtred, and the Flux was yet hardly ſtopped. The Hæmorrhage being ſtayed, the Youth ſlept ſoundly, and all that day became ſleepy; yet often awaking, he remained well in his Senſes, and was quick in ſenſe, and underſtanding; and being asked of his health, he ſaid he was pretty well; his Urine, which which was before red and troubled, then appeared pale, thin, and with a laudable Hypoſtaſis, that the Sick ſeemed (eſpecially becauſe he wanted thirſt, or immoderate heat) to be perfectly cured and freed from the Feaver: on the following Morning, being the ninth day of the Feaver, he remained yet torpid, but being raiſed up, he living chearfully and intemperance, ſeemed to be in a condition of growing well, but that he began a little to faulter in his Speech: in the Evening, when it was leaſt ſuſpected, the Feaver being again enkindled, on a ſudden he fell into a Lethargy, that he was ſcarce able to be awakened from ſleep, and being pulled, ſcarce to know any body, or to ſpeak plainly; although ſo great a loſs of Blood had gone before, the Pulſe was yet quick, high, and vehement; alſo the Urine red; after deriving and withdrawing Remedies had been uſed all that night, this Youth ſeemed to be in a little better condition, ſo that in the morning, he continued a long time from Sleep, but began to rowl about his Eyes hither and thither, and to ſet himſelf up a little; yet without ſpeaking, or knowledge of thoſe that were about him: before noon, his Eyes being ſhut again, he wholly loſt the uſe of every Animal Faculty: he lay for three days as it it were Apoplectick, with an high and vehement Pulſe, with a palpitation of the Heart, and a difficult and painful breathing; his Pulſe at length growing leſſer by degrees, he died the thirteenth day of the Feaver.

On the fifteenth of *February*, his Siſter ſomewhat leſſer than he was, began to complain of a pain and torment in her Belly, a trembling in her hands, and a painful tenſion or ſtretching out of the Muſcles of her Neck, with a feaveriſh intemperance and thirſt: on the laſt day of *February*, ſhe growing plainly into a Feaver, could not keep out of her Bed: moreover, ſhe was troubled with a wandring heat, now in her Face, now about her lower parts; alſo ſhe became heavy and ſomnolent, and awaking from ſleep, could not preſently come to her ſelf. On the firſt of *March* ſhe was lightly Purged and with eaſe, with an expreſſion of Rhubarb: her Urine was thick and red; alſo petechial red ſpots (as in the reſt) were conſpicuous: we gave her after that, for four days, at ſeveral times, to wit, after the interval of every ſix hours ſpace, ten drops of the Spirit of Harts-Horn, in a ſpoonful of Cordial Julep; the aforeſaid Symptoms afterwards leiſurely remitted, and this ſick Child, though ſlowly, recovered health without any manifeſt through Criſis.

About the ſame time her little Brother, younger than any of theſe, fell ſick almoſt after the like manner; who, yet, a Looſneſs ariſing naturally of it ſelf, for many days, voyding Cholerick and greeniſh ſtuff, was eaſily cured. Alſo in the ſame Family, many other Domeſticks, and ſome Strangers coming to help them, the evil being propagated by Contagion, fell ſick of the ſame Diſeaſe: who notwithſtanding, at length became well, though with difficulty, and ſlowly, without any regular Criſis being made.

That this Feaver was malignant, plainly appears by the Contagion, Mortality, and Appearances of Spots, and many other ſigns; though that infecting Contagion, whereby it ſpred from one to another, ſhewed it ſelf ſlow, and of leſſer efficacy; becauſe, between the Sickneſſes of each

each of them, many days, and oftentimes weeks hapned to be, that the Infection of this though acute Diſeaſe, and the diſſemination on others, was ſcarcely finiſhed in four months ſpace, in the ſame Houſe. The Feaver about the firſt beginning ſeemed gentle and mild, not very terrible as to burning; but the matter being heaped together, from the deflagration of the Blood, became preſently untameable, hard to be exterminated, alſo enemical to the Brain and Nervous Stock; wherefore in each of them, the beginning of the Diſeaſe was to be known rather by the torpor and ſomnolency, than the fervor and heat; alſo the Criſis, though by ſeveral ways attempted, *viz.* by Sweat, Flux, Bleeding, did not happily ſucceed, but for moſt part, the Blood growing turgid with the Critical Motion, endeavoured to transfer the Feaveriſh matter, upon the dwellings of the Animal Spirits; yet it ſelf notwithſtanding, became not putrefied by this means, but that about the ſtanding of the Diſeaſe, both humors (to wit, the Blood, and Nervous Juice) being vitiated, by an impure mixture together, and grievouſly touched, cauſed the event of the Diſeaſe, to be either deadly, or extream dangerous.

CHAP. XV.

Of the Meaſles and Small Pox.

IN the next place, we refer the Small Pox and Meaſles to the Rank of Peſtilential and Malignant Feavers, which indeed are mixt Diſtempers, conſiſting at once according, and contrary to our Nature. As to their Original, they have their Seminary born with us: but as to the effect, they produce preternatural Symptoms, and (as the Plague it ſelf) poyſonous; ſo that they conſtitute as it were a certain peculiar kind of Feavers, proper indeed to men, but after another manner, than *Porphyrius* has aſſigned; for it happens for every man only, and once to be diſtempered with the Small Pox or Meaſles: if perchance any one lives free their whole life, or another more often fall into theſe Diſtempers, they are rare and unuſual events of Nature, which leſſen not common obſervation; yea 'tis fully confirmed, to wit, that all, and only men are obnoxious to the Small Pox and Meaſles, and are wont to be rid of them at one Sickneſs. Concerning the Small Pox, we will treat of them apart from the Meaſles, what the Cauſe of them is, then what Signs and Symptoms they have, and laſtly, what things belong to the Criſis and Cure.

Concerning the Cauſes, we ought to conſider in the firſt place, what is the ſecret leading Cauſe, to wit, which renders only and all Mankind, and that once, obnoxious to this Diſeaſe. Secondly, We will enquire concerning the evident Cauſes, *viz.* by what and how many ways, this latent and occult diſpoſition is wont to be, now ſooner now later, deduced into Act. Thirdly, It ſhall be declared, what is the conjunct Cauſe, to wit, by what motion and alteration of the Blood, the figure of this Diſeaſe is produced.

1. As to the firſt, This diſpoſition or natural prediſpoſition, which inclines humane kind to this Diſeaſe, ſeems to be a certain evil or impurity of the Blood, conceived in the Womb, among the firſt Rudiments of Generation; almoſt all Authors would have this aſcribed to the Menſtruous Blood; which Opinion ſeems not altogether improbable; becauſe in a Womans Womb (otherwiſe than in moſt other living Creatures) there is generated a certain Ferment, which being communicated to the Maſs of Blood, affords to it Vigor and Spirit, and then at ſet periods, procures a ſwelling up, and an excretion of the ſuperfluous Blood; but at the time of Conception, when the *Menſtrua* wholly ceaſe, very much of this Ferment is beſtowed on the *Fœtus* or Child; and its Particles being heterogeneous to all the reſt, as a certain extraneous thing, are confuſed with the maſs of Blood and Humors; with which being involved, and ſeparated one from another, lurk or lie hid a long while; yet afterwards at ſome time, being moved or ſtirred up, by ſome evident cauſe, they ferment with the Blood, and induce to it an Ebullition, and then a Coagulation, from whence very many Symptoms of this Diſeaſe ariſe.

Theſe Fermentative Seeds ſometimes are few and gentle, and ſo involved with other little Bodies, as they do not eaſily appear, and are brought into act; ſometimes they are more and ſtronger; ſo that on the leaſt occaſion they are ripened into this Diſeaſe; hence indeed ſome are taken ſooner, with the Small Pox in their tender years; others more ſlowly, and not till full or more ripe Age; alſo ſome eaſily receive the Contagion, but others converſe often with the ſick without danger. The ſooner that any one hath this Diſeaſe, the more ſecure they are; wherefore Children moſt often eſcape; old men, or ſuch as are of years, are more in danger, *viz.* in Children or young people, Tranſpiration is more eaſie, alſo the habit of the Body

more

more firm and healthful. But altho the venomous ſeeds of this Diſeaſe, for the moſt part are wont to be diſperſed or blown away at once, and with one ſickneſs; yet it ſometimes happens, that a part of the infection being ſtill left, the ſick have fallen into this Diſeaſe twice or thrice.

2. The evident cauſe which ſtirs up theſe fermentative ſeeds, and moſt often brings them into act, may be ſaid to be threefold, *viz.* The contagion received from ſome place: the diſpoſition of the Air, and the immoderate perturbation of the Blood and Humors. It is moſt manifeſt by daily experience, that this Diſeaſe doth come upon others, and ſpread abroad by contagion; *viz.* from the infected Body, continually flow *Effluvia*, which being received by other Bodies, preſently like poyſon, they ferment with the Blood, and ſuſcitate or awaken the lurking or ſleeping Seeds of the ſame Diſeaſe, homogeneous with themſelves, and diſpoſe them into the Figure or Idea of this Diſeaſe: neither is the Infection only communicated by contact, but at a diſtance. They who live within the ſame Houſe, or neighbouring to the Sick, eaſily receive the Infection; alſo it is cheriſhed in Cloaths, and diſſipated afar off, and transferred to more remote places. They who are of kin one to another, ſooneſt infect each other; alſo they who are fearful, and extreamly dread this Diſeaſe, more readily fall into it: For by Fear, the Particles of the Infection are conveyed inwardly from the ſuperficies of the Body. At what time the Contagion ſpreads, and that the Small Pox are Epidemical, all other Diſeaſes almoſt degenerate into this. Secondly, a certain peculiar diſpoſition of the Air, notably induces the Small Pox; hence moſt often it becomes popular, and rages ordinarily through whole Regions, Cities and Villages; hence alſo it more often exiſts in the Spring and Autumn: becauſe at that time eſpecially divers manners of little Bodies, and by that means tumultuating flow about in the Air, which we draw in with the Air, and ſo various effervescencies of the Blood and Humors, and Idea's of Diſeaſes are raiſed up. Neither doth this Diſeaſe become only more frequent and Epidemical for theſe Cauſes, but alſo it gots a manifold Nature, that ſometimes the Small Pox are deadly, and as it were peſtiferous, and ſometimes they are more mild and benign; to wit, as they have contracted more or leſs of Malignity from the Air; hence alſo ſometimes black and livid Whelks or Puſtles appear, and have much of the Nature of the Plague. Thirdly, Sometimes, though the Tinder of contagion be abſent, and that no malignant Conſtitution of the Air had gone before, yet by reaſon of the Blood and Humors being immoderately diſturbed, the Small Pox do ariſe: ſo I have known ſome to have fallen into this Diſeaſe, from a Surfeit, or immoderate exerciſe, when none beſides in the whole Country about, hath been ſick of it, to wit, the Seeds of this evil, lying hid, without any previous infection, being ſtirred up by a too great fervor of the Blood, and being aſſociated, gathering together, eaſily defile, and infect the whole Maſs of the Blood, with their Ferment,

3. So much for the ſecret leading, and evident Cauſes, but as to the conjunct Cauſe, *viz.* which is the formal reaſon of this Diſeaſe, or the manner of its being made, the buſineſs ſeems a little more intricate. It is commonly wont to be compared to Muſt growing hot, or Beer when it purges in the Vat: for if you put to theſe Liquors any thing of Ferment: as their Particles are heterogeneous, and of wonderful activity, preſently they diffuſe themſelves through the whole ſubſtance of the Liquor, they exagitate the more thick and impure Bodies, againſt which they are daſhed, beat them aſunder, and roul about them, until a flowring being made, they drive the ſame from the intimate embrace or company of the Liquor, to the outmoſt Superficies. After the like manner the heterogeneous Seeds of this Diſeaſe, are thought to ferment the Blood, and then by a certain eruption of Whelks or Puſtles, like the flowring, purifies it. But indeed, if we ſhould more ſtrictly conſider the Buſineſs, there will appear here a great difference; becauſe the infection of the Small Pox, is as it were a Ferment, or corruptive, and compels the Blood to grow hot, not towards perfection, but depravation; for when the Particles of this venomous infection ſtrike againſt the receiving Subject, they preſently raiſe up little Bodies like to themſelves, and born with us, with which being aſſociated, they paſs through the whole Maſs of the Blood, and make it to grow highly turgid, and to boil up, and after ſome time growing fervent, to go into parts, and to be coagulated, *viz.* the diſperſed Seeds of the Poyſon, diſſolve the mixture of the Blood, preſently profligate the more pure Spirits, then they joyn its more thick Particles to themſelves, and by their adheſion, render them as it were congealed: The portions being ſo coagulated, together with the infolded Seeds of the Poyſon, being left by the reſt of the Blood, in its circuit, between the extremities of the Veſſels, are affixed to the skin: by which means, if Nature being ſtrong enough, doth caſt forth the whole poyſon, with the congealed Blood, the remaining Maſs of the Blood, although made poorer, remains however in a condition to continue Life and Health; but if the Blood, being too exceſſively congealed, cannot be purified after this manner; or if portions of the Blood growing together with the Poyſon, do not fully break forth, or at laſt do ſtagnate within, they wholly corrupt the Liquor of the Blood, or elſe being affixed to the Viſcera, and eſpecially to the Heart, they deſtroy their conſtitution and ſtrength.

Portions of the congealed Blood, with the Poyſon, begin to break forth about the fourth day (now ſooner, now later) becauſe Coagulation is not preſently induced, but after ſome time,

in

in which the Venom unfolds it ſelf, and ferments the Blood with its Effervency: Firſt, light portions of the infected Bloud, and thoſe but few in number, like to Flea-bites, are fixed in the Skin; quickly after more appear, and thoſe firſt broke forth, by the acceſſion of new Matter, and by the continual appulſion of the congealed Blood, increaſe, and are elevated into a tumor; then theſe Whelks at firſt red, being by degres increaſed, at length grow white, *viz.* the Bloud being thruſt forth of the Veſſels with the Poyſon, by reaſon of the heat and ſtagnation, is changed into Matter: about the ſeventh day after the eruption, the white tumors grow cruſty, into a dry Scab; for the more thin part of the matter being evaporated, the reſt grows hard, which then having eaten, and broke off the Cuticula, or outward thin Skin; falls away from the fleſh or next Skin.

When the infection of the Small Pox is at once impreſſed on the Blood and Spirits, it very rarely can be blotted out, or diſſipated by Medecines, or Bloud-letting; but that its hidden diſpoſition, will break forth into act; wherefore at firſt it diffuſes it ſelf by little and little, and inſpires the maſs of Bloud, as it were with a Ferment, hence an ebullition and growing hot are produced in the whole Body, the Veſſels are diſtended, the Viſcera provoked, the Membranes pulled, until the Seeds of the Contagion, by fuſing and coagulating the Blood, being at length involved with its congealed portions, are thruſt forth of doors. The Eſſence of this Diſeaſe will be better laid open, if that I ſhall recount the Signs and Symptoms, which are to be obſerved in its whole courſe, and ſhall add in order the Reaſons and Cauſes of them, on which they depend; but they are thoſe which either indicate the Diſeaſe being preſent, or that foretel its ſtate and event.

As to the Diagnoſis of this Diſeaſe, by which it may be known, whether any one at firſt falling ſick, will have the Small Pox or not; at that time are to be conſidered, the force of the Contagion, and the concourſe of the Symptoms firſt appearing; for if by reaſon of the evil conſtitution of the Air, this Diſeaſe doth ſpread abroad every where, none then is taken with a Feaver, without the ſuſpition of the Small Pox, eſpecially if they never had them before in their lives; but if this Diſeaſe be more rare, and without fear of Contagion, yet its unlooked for Aſſault quickly betrays it ſelf, by theſe ſort of Signs and Symptoms.

1. There is a wandring and uncertain Feaver, ſometimes ſtrong, ſometimes more remiſs, obſerving no reaſon of increaſe, or growing continually hot, ſo that the Sick are now highly hot, by and by without any evident cauſe, they are without a Feaver; the cauſe of which is, for that the fermentative Seeds are not agitated by an equal motion, but like fire half choaked, now increaſes more, and now are almoſt quelled, and ready to expire; until the burning ſpreading more largely, the flame every where breaks forth.

2. A pain in the Head and Loins, is ſo peculiar a Sign in this Diſeaſe, that it almoſt alone, in a continual Feaver, ſignifies the approach of the Small Pox; the reaſon of which is commonly imputed to the greater Veſſels being very much diſtended by the effervency of the Bloud; but indeed it appears not, wherefore the ſame trouble is not cauſed equally in other parts, by reaſon of the like diſtention of the Veſſels, and wherefore in the Small Pox, more than in a burning Feaver, or in other Feavers, where the Bloud grows more hot, theſe kind of pains ſhould increaſe; yea, it may be obſerved, that great pains, now in the Head, now in the Loins, do urge, when the Blood but little ſwelling up, the Veſſels are not amplified, *viz.* in the beginning of the Diſeaſe, when the Feaveriſh diſtemper is not yet conſpicuous, while the ſick as yet go abroad, and are well in their Stomach, upon the firſt coming on of the Small-Pox, they betray themſelves by theſe kind of Pains. Wherefore, the cauſe of theſe kind of dolorifick pains, ſeems rather to ſubſiſt in the nervous ſtock, *viz.* in the Brain, and ſpinal marrow, and that by reaſon of the membranes, and nervous parts being pulled or hauled by the particles of the poyſon, theſe pains do ariſe. For it is moſt likely, that the innate ſeeds of the Small Pox are chiefly hidden in the Spermatick parts, and that firſt of all, the Contagion lays hold on, for the moſt part, the Animal Spirits; hence, the firſt efferveſcency is ſtirred up in the Juice, wherewith the Brain and nervous parts, but eſpecially the Spinal marrow are watered, and from thence the evil is communicated to the maſs of Bloud; wherefore, this Diſeaſe beginning, the Head and Loins are tormented with cruel pain; afterwards, the venom being tranſlated into the Blood the Feaveriſh efferveſency is ſtirred up in the whole.

3. Great anxiety, and unquietneſs, and ſomtimes a ſwooning, infeſt the ſick, *viz.* by reaſon of the perturbed motion of the Blood, as alſo its equal mixture, beginning to be ſolved, by the Poyſonous ferment, the Blood from thence being apt to ſtagnate in the Heart, and to be hindred in its Circuit, cauſes theſe affections to be thus excited.

4. Cruel Vomiting, alſo when the Ventricle is free from an impure ballaſt of Humors, very often accompanies this Diſeaſe; the reaſon of which is, becauſe the fermentative ſeeds, being ſtirred up into motion, by the little Arteries gaping into the coats of the Ventricle, are depoſed by every appulſe of the Blood, and raiſe up Vomiting, as if the particles of Stibium had been ſwallowed; but afterwards, aſſoon as ſweating being procured, the Poyſon is driven forth outwardly, this Symptom ceaſes, and the Sick are well in their Stomach, without any purging forth of the noxious matter.

5. With

5. With these may be ranked, the Symptoms which shew themselves, according to the various habitudes of the Body, after a diverse manner, as heavy sleepiness, terrors in sleep, deliriums, tremblings, and convulsions, sneezing, heat, redness, a sense of pricking over the whole Body, involuntary tears, a sparkling, and itching of the eyes, a tumor or swelling up of the Face, a vehemency of Symptoms from the beginning, that the Disease seems presently to have attained his strength: the reason of all which may easily be elucidated, if what hath been already said concerning the Symptoms of Feavers be observed; with respect to the diverse tempers of the Sick, their habit, and age, as also the condition of the year.

2. As to the Prognosis of this Disease, by the Symptomatic Signs, it is indicated to be either salutary, or mortal, or of a doubtful Event.

1. The business promises well, when this Disease has benign circumstances; to wit, when it happens in a good constitution of the Air and Year, and at what the Small Pox are less malignant and pestilential; as in the year 1654. at *Oxford*, about Autumn, the Small Pox spred abundantly, yet very many escaped with them: but before, in the year 1649. this Disease was more rare, yet most died of it. Also, there is less danger, if it should happen in the age of Childhood or Infancy, or in a sanguine temper, and good habit of Body, or in a Family to whose Ancestors the Small Pox have not proved mortal: Besides, if in the whole course of the Disease, the Symptoms prove laudable, if in the first Assault, there be a gentle Feaver, without cruel Vomiting, Swooning, Delirium, or other horrid Distempers; if the Feaver about the fourth day be allayed, with the Symptoms chiefly urging, and then some little red spots begin to appear; if on the second day of the coming forth of those little red spots, they become more conspicuous, which afterwards grow together by degrees into little Pimples, and are ripened into Matter; if about the tenth day, or thereabouts, after the Eruption, the white tumors begin to scab, and by little and little from thence to fall off; if after their first coming forth, the Small Pox are soft, distinct, few, round, sharp-pointed, lying only towards the skin, and not in the inward Parts, you may be confident the Sick will do very well, and is in a good condition.

2. The appearances, which in the Small Pox, signifie the business to be suspected, and full of danger, are of this sort; if there be a malignant constitution of the Air, that this Disease becomes Pestilential, and many die of it; if men of more ripe years, or middle Age, be taken with it; if it happens in a cold and melancholick temper, or in an impure or evil humor'd Body, where the Bloud is not rightly circulated, nor transpiration truly performed, or if the Hypochondria or Præcordia are obstructed, some of the Viscera infirm, or troubled with an Ulcer, or if the habit of the Body be too fat, the Small Pox happen not without great danger of Life; nor is it less to be feared, when presently after the beginning, a great Feaver, cruel Vomiting, Swooning, a dejection of strength, Phrensie or Delirium come upon them, and that these desist not, upon the full coming forth of the Small Pox, for these signifie a too great perturbation in the Bloud and Humors; also, a confusion and contumacy of the morbifick matter, which can neither be subdued, nor easily separated from the mass of Bloud, or equally extruded from it: if there be an anxiety, and great unquietness, with an inordinate boiling up, and growing hot of the Bloud; also a great thirst, a difficulty of breathing, also a flux of the Belly, or Dysentery, they shew that sweating is hindred, and that the malignant humors restagnate towards the inward parts: The small Pox breaking forth slowly, argue the crudity and untameableness of the matter, and the impotency of Nature, and 'tis much more a sign, if they come forth double, and continued, in too excessive a quantity and confusion, and also if there be a disordered expulsion, and irregular, of that matter, when not in certain issues, but every where undistinguishable. The Pox being hard, signifie the incoction of the same matter, being depressed, a weak expullion; and they are the worse, if in the midst of them appear black spots; or if purple spots familiar to the Feaver, or the Plague, are sprinkled among the Pox, they indicate a great malignity and putrefaction of the Bloud, such as is wont to be found in the Pestilence. Lastly, the Pox being black, livid or green, are of an evil omen, because, besides the coagulations of the Bloud, they argue its deadlinesses and corruptions, as in a Gangreen or Pestilent-Plague-Sore; if when the small Pox being come forth, they presently grow dry, and the swelling of the parts remit, it shews a going back of the malignant matter, or of the congealed Bloud, with the Poyson, and a restagnation of it to the inward parts; from whence, unless a more free Diaphoresis or sweating be excited, that it may be thrust forth of doors again, Death for the most part quickly follows: For from hence the Bloud being more coagulated, enters into putrefaction, also it is apt to be hindred in its motion, and to stagnate in the Heart and Vessels. If after the coming forth of the small Pox, a flux of the Belly, or a bleeding at Nose, comes upon them, it is an evil sign, because, by this means the Venom driven outwardly, is again called back inwardly; but sometimes I have observed these Symptoms to have hapned, with great ease to the sick, *viz.* Nature being before oppressed and burthened; after this

manner, part of the burthen being as it were detracted, ſhe was eaſed; wherefore, ſhe buckled her ſelf to the work of ſweating, and more readily expedited the expulſion of the noxious matter.

As to the Curative part, ſince the ſtadium or courſe of this Diſeaſe, hath three Seaſons, as it were ſo many meaſures, diſtinct one from another, the Curative intentions ought to be accommodated to each of theſe; wherefore the Curative Method concerning the Small Pox, teacheth firſt, what is to be done ſo long as the Bloud boyls up, and grows hot inwardly, with the motion of the fermentative matter, and before the ſmall Pox appear, which period for the moſt part is finiſhed in four or five days.

Secondly, what means or manner of Diet and Phyſick is to be inſtituted, after the coming forth of the ſmall Pox, until the ſtate or ſtanding of the Diſeaſe, *viz.* whilſt the Whelks or Pox come to the height, and being fully ſuppurated or ripened, begin to dry.

Thirdly and laſtly, what we muſt obſerve in the declining of the Diſeaſe, even whilſt the ſmall Pox growing dry, fall off.

1. As to the firſt, let the Intention be, that we may carry away every impediment of Nature, whereby the Bloud being infected by the Ferment of the ſmall Pox, and apt to be coagulated, may yet retain an equal motion in the Heart, and without ſtagnation in the Veſſels, and growing hot, may expel forth of doors the congealed portions with the Poyſon; in the mean time, there muſt be a caution, leſt the work of fermentation or growing hot be any ways hindred, or too much provoked; for by this the Maſs of the Bloud is agitated into congealed portions, more than it ought to be; by that other it is reſtrained too much in its motion, nor are the invenomed Particles ſent forth of doors with the congealed Bloud; Nature in the work of ſecretion and expulſion, is wont to be hindred by too great an heap of excrements in the Viſcera, or by the abundance of Bloud in the Veſſels; wherefore upon the firſt aſſault of the Diſeaſe, care muſt be taken, that if need be, an evacuation by Vomit or Stool, be timely procured; but only more mild Purges, and gentle are to be uſed, which do not too much provoke, or diſturb the Humors: wherefore, at this time, Purges, Emeticks, or Clyſters, now theſe, now thoſe, take place; alſo the letting of Bloud, if there be a fulneſs, is performed with good ſucceſs.

During this growing hot of the Bloud, Diet ought to be inſtituted ſlender and moderately cooling, *viz.* Barly-Broth, or Grewel of Oatmeal, Poſſet Drink, Small Beer, or the like: Fleſh, and Fleſh-Broths are to be avoided, whereby the Bloud, by reaſon of the too great plenty of ſulphureous Food, may be enkindled more than it ought; alſo all cold, and ſharp or acid things are hurtful; for theſe congeal the Bloud more, and contract the little mouths of the Veſſels by their aſtriction or binding nature, that the ſmall Pox come forth leſs freely; alſo hot things, and Cordials are cautiouſly to be adminiſtred; for by theſe the Bloud and Humors are too much agitated, and driven into confuſion.

2. When the Small Pox begin to appear, there are three things, which by a conſtant Rule we preſcribe to be performed to every ſick perſon, to wit, that a ſoft and gentle Sweat be ſtill continued in the Bloud; alſo, that the Throat and Eyes may be preſerved from a too great eruption of the Small Pox. That the Bloud lightly growing hot may emit the Small Pox, Decoctions of Figs, Marigold flowers, and ſhavings of Harts-horn in Poſſet-drink, are commonly preſcribed, and the uſe of them is general for a long time, almoſt with all people; for the ſame intention, we are wont ſometimes in a day to give them moderate Cordials; but the more hot and ſtrong are carefully to be ſhunned: Purging and Bloud-letting here are moſt wickedly enterpriz'd, and theſe, though Neceſſity compelled, Phyſicians dare not meddle with for fear of blame: For to defend the Throat and Guttural parts, we put on the outer Skin a defence of Saffron dipped in Breaſt-Milk, and ſewed in a Rag; for theſe, by opening the pores, draw away the venom outwardly, from the moſt inward part or the Throat; alſo for this end, we adminiſter Gargariſms, and things to waſh the Mouth, which by their reſtriction, reſtrain the coming forth of the Small Pox within: we defend the Eyes with peculiar Medecines, of Roſe-water, and Breaſt-Milk, with Saffron, and ſuch like, frequently iterated, from the incurſion of the Small Pox: Beſides theſe, ſometimes certain moſt horrid ſymptoms do trouble, which muſt be timely helped with convenient Remedies; ſometimes there are preſent, Watchings, Phrenſie, Bleeding at Noſe, Vomiting, Looſneſs, and a falling back of the Small Pox: for theſe and divers others, as occaſion ariſes, a prudent Phyſician knows how to provide; in which however there is need of great caution, leſt whilſt we take care of the ſmaller matters, the great work of Nature ſhould be diſturbed by a too great moleſtation of Medecines. For in all this time there is one and a continued Criſis: wherefore nothing is to be medled with raſhly. There is required the moſt care and circumſpection of the Phyſician and Nurſes, or thoſe that adminiſter to the Sick, when this Diſeaſe is at its height or ſtanding, *viz.* leſt that when the Small Pox be fully come forth, and brought to their greateſt height, tranſpiration ſhould be hinder'd; for then the ſick are in danger of renewing the Feaver,

and

and of the reſtagnation of the Malignant matter within, whilſt we ſtudy to prevent the one, we for the moſt part bring on the other.

3. When the Diſeaſe ſhall be in its declination, and the Small Pox begin to wither and ſcab, the buſineſs for the moſt part is out of danger, nor is there much need of a Phyſician; let the ſick, though he grow very hungry, content himſelf ſtill with a ſlender Diet, and without Fleſh: if the Scabs fall off ſlowly, we are wont to ripen them with Liniments, and peculiar Medecines, to make them fall, and care ſhould be taken that they leave not behind them too great Pits: after the Sick having the Scabs every where fallen off, and are able to riſe and walk about the Chamber, the filthy Excrementitious Matter in the Bowels, is to be carried away, by two or three times Purging, and then they may be permitted to uſe a more plentiful and ſtronger Diet.

The Meaſles are ſo much akin to the Small-Pox, that with moſt Authors they have not deſerved to be handled apart from them, but that either Diſtemper have been treated of together, after the like manner and method. The Eſſence and Cure differ at leaſt accidentally, or as they are greater or leſſer; becauſe in the Meaſles the Whealks riſe not up to ſo great a Bulk, neither are they ſuppurated; wherefore the Sickneſs is ſooner ended, and with leſs danger. this Diſtemper is wont moſtly to ſpread upon Children, more rarely amongſt thoſe of years, or old men; alſo thoſe who firſt have had the Small-Pox, are not afterwards ſo obnoxious to the Meaſles, but in moſt things, either Diſtemper are of kin, *viz.* the Evil being contracted in the Womb, diſpoſes men only, and all men once to the Meaſles; the malignant conſtitution of the Air, and ſometimes a Surfeit, and moſt often the Contagion, are wont to bring the hidden diſpoſition into act; there are preſent marks of malignity, and the Sickneſs oftentimes becomes Epidemical, and with Mortality and Contagion.

That I may briefly contract the Sum of the Matter, it ſeems that the Meaſles are a certain lighter flowring, of an extraneous ferment, contracted from the womb; by which, ſome Particles being ſtirred up into motion, make the Blood lightly to grow hot, and to be a little coagulated; wherefore the Marks from thence ſpread abroad, are diſſipated without any breaking of the Cuticula, or outward Skin, by evaporation only; but the Small Pox are a more full and ſtrong agitation, according to all the Particles of the ſame Ferment, which cauſing a great ebullition and coagulation of the Blood, produces far more full whelks, and greater in bulk, and not to be diſſolved, but by ſuppuration, or growing into matter: when the Small Pox precede, they are not only exempt from the ſame Diſeaſe any more, but alſo from the Meaſles, becauſe they conſume only ſome of the Particles of the Ferment, leave ſtill a diſpoſition to the Small Pox; wherefore old men, or thoſe of years, are not ſo readily infected with the Meaſles, becauſe they are either freed from the contagion, by having before had the Small Pox, or elſe the Infection of this more light Diſeaſe, is eaſily reſiſted by their more ſtrong Spirits.

It were eaſie to illuſtrate the afore-cited Doctrine concerning the Small Pox, with Hiſtories and Obſervations of the Sick, becauſe there is no Diſeaſe beſides can ſupply with a greater plenty of Examples, or variety of Accidents; but of the great number of this kind, I ſhall only propoſe in this place a few Caſes, and thoſe remarkable for ſome irregularities.

It is a uſual thing to handle all that are ſick of the Small Pox, with a like, or wholly the ſame method of Curing, and manner of Diet; wherefore, a Phyſician is rarely ſent for to the common ſort, but the buſineſs is wholly committed to ſome Women, profeſſing themſelves skilful in this Diſeaſe; and theſe are wont to boil in their Broths, and all the Suppings of the ſick, Marigold-flowers, ſhaving of Harts-horn, and ſometimes Figs; alſo every night to adminiſter a Bolus of Diaſcordium; and they who grow not well by this kind of Government, though not neglected, yet are affirmed to be incurable, by reaſon of the cruelty of the Diſeaſe. But truly this kind of Practice is not convenient for all alike, nor to be adminiſtred to every one indifferently; as theſe two following Hiſtories will make manifeſt.

A young Man, about 20 years of Age, of a ſlender Body, and more hot temperature, began to be Feaveriſh in the beginning of the Spring, at firſt cruel Vomitings, an oppreſſion of the Heart, and frequent changes of heat and ſhivering, a pain in his Loyns, a diſturbance of his Fancy, and Wakings infeſted him; on the third day, the Small Pox appearing, thoſe Symptoms remitted, but ſtill the Feaver, with heat and thirſt continued. Not only the accuſtomed Decoctions in this Diſeaſe, but alſo a moſt elegant Julep, of a moſt grateful taſte, were ſo nauſeous and troubleſome to him, that he would not ſo much as taſte the ſame, but with a great deal of trouble; as often as he took going to ſleep, Diaſcordium, or any other more temperate Cordial, for the continuing his Sweat, though in a very little quantity, the night following he was without ſleep, and in great diſquiet; and then in the beginning of the morning a Bleeding followed, by which means indeed, the Small Pox being full come forth, the Life of the ſick was in great danger, by reaſon of this occaſion hapning once or twice; where-

fore, when I had found by obſervation, his Blood apt to grow immoderately hot, by ſo light a provocation, I inſtituted this method as occaſion ſerved. All Medecines being let alone, he took for the quenching his Thirſt, ſmall Beer, and ſimple Almond-Drink, at his pleaſure: for his Food, becauſe he vomited back all Oatmeal Grewel, or Barly-Broth, he eat only Apples roaſted tender, and dreſt with Sugar and Roſe-water, often in a day. Nature being contented with this ſlender ordering, and being ſeen to be diſturbed with any other thing performed happily its work, that the ſick perſon grew well, without any grievous Symptom afterwards, the Small Pox from thence ripening, and then of their own accord falling off.

In the middle of Autumn of the former Year, a Gentile Young Man, being endued with a ſharp Blood, and obnoxious to a frequent bleeding at Noſe, fell ſick of the Small Pox; his Blood of its own accord grew immoderately hot, that the Whelks very quickly broke forth over all his Body: Poſſet-Drink, with Marigold-Flowers, and other uſual things boiled in it, alſo Juleps, or any Cordials, though temperate, and gently provoking Sweat, moſt certainly ſtirred up a Flux of Blood in this Perſon; wherefore I ordered the like manner of Diet, as in the ſick perſon before cited, by which he found himſelf better; however, in the very ſtate or ſtanding of the Diſeaſe (when the Small Pox being fully come forth, by reaſon of a more difficult tranſpiration, the Feaver is wont to be ſomewhat renewed in all) this ſick man fell into a moſt plentiful Bleeding; that after a large profuſion of Blood, the Small Pox began to flagg or fall: After that Remedies, very many, were tried in vain, for the ſtaying of the Blood, at length a little Bag being hung about his Neck (in which was a Toad dried in the Sun, and bruiſed) he firſt, and immediately perceived eaſe; though the bleeding was by this means ſtayed, and not any more returning (whilſt he conſtantly wore this peculiar Medecine in his Boſom) our ſick Man ſtill uſing a moſt thin and cooling Diet, grew quite well; that indeed from hence it may appear, that although the Blood in this Diſtemper, is apt to be greatly coagulated, yet ſo long as the vital Spirits, being ſtrong and robuſt, are able ſufficiently to execute their government, they endeavouring by their proper ſtrength or forces, do beſt of all ſeparate and thruſt forth the congealed portions of the Blood, as it were by a certain skilful ſeparation; and this work is moſt of all hindred, when the ſame Spirits are too much irritated by Cordials, or more hot Food, and agitated into confuſion: But in the Plague it happens otherwiſe, becauſe in this, if any delay be granted, the Spirits themſelves are preſently profligated by the Venom; wherefore, here they muſt fight cloſe and quick, when in the Small Pox, the Phyſician does his buſineſs better by delay.

Concerning letting of Blood, at the inſtant breaking out of the Small Pox, it is very dubious; formerly, among our Countreymen, this was eſteemed a wicked buſineſs, neither were they wont to admit of Phlebotomy under any pretext of neceſſity: but of late, experience having taught us, in ſome caſes, it is found, that to let Blood, hath been wholly profitable and neceſſary; which evacuation however, if it ſhould be adminiſtred indifferently in every conſtitution, or when this need ſhould be, it ſhould be performed in too large a quantity, by that means oftentimes very great dammage ariſes.

Some years before, I viſited a young Gentlewoman, of a florid countenance, and more hot temperature, growing into a Feaver, after the fourth month of her being with Child; ſhe was troubled with a cruel Vomiting, a moſt cruel pain of the Loins, beſides with moſt ſtrong heat and thirſt; her Pulſe was ſwift, with a ſtrong and vehement vibration or beating; altho the Small Pox had never been in that Place, yet theſe Symptoms gave no light ſuſpition of this Diſeaſe; however, its great effervescency indicated that Blood ſhould be taken away; wherefore I took away about ſix ounces preſently, upon which the heat remitted ſomewhat, yet the Vomiting, with a cruel pain in the Loins remained ſtill: At the hour of ſleep, I gave her a Cordial Bolus, with half a grain of our Laudanum, by which means quiet ſleep followed, with a pleaſant ſweat, and an allaying of all the Symptoms: the next morning the Small Pox came forth, with which, although the ſick Gentlewoman was greatly diſtempered, yet ſhe grew well without any dangerous Sickneſs, or fear of miſcarrying, and went out her full time.

The laſt Autumn, a ſtrong Man, of an active and robuſt conſtitution of Body, yet of a pale Countenance, and more cold Temper, fell into a Feaver; on the ſecond day he was tormented with heat and thirſt, and a moſt cruel pain in his Loins: when I had preſcribed Blood to be taken in a ſmall quantity, the unskilful Chirurgeon, who was ſent for, took from him almoſt half a pound; a little after, the ſick man began to be all over in a cold ſweat, on a ſudden to loſe all ſtrength, to be troubled with a ſhivering, a weak Pulſe, and unequal, and frequent ſwooning. At this time being ſent for, I gave him a temperate Cordial, to be taken frequently. His Spirits and Pulſe being thereby reſtored, the Feaver was renewed, which afterwards, for ſome days, yea, weeks, exerciſed the ſick man after a very irregular manner; for he was wont for three or four days to grow very hot, alſo to be infeſted with thirſt, watchings, Head-Ach, and other Symptoms, then to be troubled all over with a copious and critical

cal ſweat, by which indeed for half a days ſpace he found himſelf better; but from thence, the Feaver ſtill growing worſe, heaped together again new matter, till it was diſperſed by another Criſis, and then another. After that he had been thus feaveriſh for at leaſt twenty days irregularly, at length the Small Pox began to come forth in ſeveral parts of his Body, here and there, and then the Feaver wholly remitted; yet within few days, by reaſon of ſome Errors committed in his Diet, very many of the Whelks began to fall down again, few of them only being brought to maturity: However, inſtead of the ſubſiding ſmall Pox, a mighty Bubo grew up behind his right Ear; from which, being ſoon ripened, and broke, a great plenty of Matter flowed forth for many days, and ſo at length the Corruptions of the Blood, unable otherwiſe to be diſſipated, were carried forth by degrees, and the ſick Perſon recovered perfect Health.

Chap. XVI.

Of Feavers of Child-bearing Women.

VUlgar Experience abundantly teſtifies, that the Feavers of Women lying in are very dangerous, beyond the diſpoſition of other common Feavers: alſo that the ſame differ very much, as to their Eſſence, from both a ſimple and putrid Synochus, plainly appear from their ſigns and ſymptoms rightly weigh'd: wherefore, I believe it not to be from the matter, to handle after Malignant Feavers, the acute Diſeaſes of Women lying in, being exceeding near of kin to thoſe, for their mortality or perniciouſneſs. Yet, before I ſhall enter upon the unfolding theſe Diſeaſes, it behoves us to conſider their Subjects, *viz.* the Bodies of Women in Child-bed, after what manner they are prediſpoſed, and by what proviſion they are made obnoxious to theſe kind of Sickneſſes.

Concerning this, the firſt thing that offers it ſelf, is, that the Flux of the menſtruous Blood is wholly convenient to be ſuffered by human kind, and at this time for Women, concerning whoſe Nature and Original we ſhall not enquire in this place; but it ſhall ſuffice to note, that in them, the particles of the Blood to be periodically thruſt forth, are very Fermentative; which, if retained in the Body, beyond the wonted manner of Nature, are very often the cauſe of many Diſeaſes; unleſs only when a Woman conceives with Child. For all the time of her being big-bellied, the monthly Flowers are ſtopped without any incommodiouſneſs; and in the mean time, Milk, or the alible Juice, is diſpoſed in great plenty, about the parts of the Womb, for the nouriſhment of the Child; but after the Birth, this daily ſuppreſſion of the Monthly Flowers is recompenſed by a copious flowing forth of the Lochia, or what comes away after the Birth; and the Milk within three days having wholly left the Womb, ſprings forth plentifully into the Breaſts: at which time, Women lying in, are wont to be troubled with a ſmall Feaver. If that the Milk be driven away from the Breaſts, it reſtagnates again towards the Womb, and is thruſt forth, together with the Lochia, under the form of a whitiſh humor. In the mean time, the Womb, after the Birth, becomes ſubject to various Diſtempers; for oftentimes its tone is hurt, the unity is diſſolved, and many other Accidents are induced, which render Women lying in, ſubject to danger: wherefore, that their acute Diſeaſes may be rightly unfolded, it is convenient to conſider chiefly theſe three things, *viz.* Firſt, The Nouriſhment of the Child, or the Generation of Milk, both in the Womb, and in the Dugs, and the Metaſtaſis or tranſlation of it from one to another. Secondly, The purging of the Mothers Blood, or the Profluvium of the Lochia, after a long ſuppreſſion of the Menſtrua. Thirdly, The condition of the Womb after the Birth, and its influence on other parts of the Body. And theſe being premiſed, we will ſpeak of the Feavers of Women lying in, *viz.* both the Milky and the Putrid, called, and that deſervedly, malignant, by reaſon of its deadlineſs.

Firſt, the Milk and nouriſhing humour, being heaped up in the parts of the Womb, for the nouriſhment of the Child, are of a like Nature, though ſomewhat different in conſiſtency. Milk is indeed more thick, becauſe it ought to be received in at the mouth, and to be kept in the Ventricle, and afterwards its more thin portion to be conveyed to the maſs of Blood. The other alible Juice is more thin, and like the Water of diſtilled Milk, becauſe it is immediately poured into the Blood of the Embryo, through the umbilick Veſſels, without any previous digeſtion. Either Juice is ſuppoſed to come from the Chyle freſh made in the mothers ſtomach; what is repoſed or laid up in the Breaſt, is more thick and white, by reaſon of the more thin or open

ſtrainer,

ſtrainer, and coction in the greater Glandula's; on the contrary, it happens in the Womb otherwiſe, where the Glandula's are ſmaller, and the ſtraining more cloſe. But there is a great diſagreement among Authors, concerning the paſſages, by which this Humour is carried, both in the Breaſts, and into the Cake of the womb. Some contend, that Milk only is begotten of the blood, more plentifuly cocted in the glandula's, which yet, by reaſon of the immenſe diſpenſe of Milk, which conſiſts not with the Blood, this ſeems not probable. Others affirm, that the Chyle, or Milky humor, is immediatly convey'd from the Viſcera of concoction, through occult paſſages, without any alteration, into either receptacles: But in the mean time, while theſe paſſages lie open, it ſeems indeed to me more likely, that from the meat taken into the Mothers Stomach, a portion of the Chyle thence made, is preſently ſupped up into the Veins, which having obtained the Vehicle of the Blood, before it be aſſimilated by it, is laid up in the Glandula's, deſtinated here and there for the receiving of it, being carried by the Arteries, and laſtly ſeparated from the Maſs of Blood; for as it appears, that Drink being plentifully taken, preſently paſſes through the whole Maſs of Blood, and is rendred by Urine like Water; and as old Ulcers, by means of the Blood coming between, prey upon the nutritious Humor, from the whole Body, and powr it forth under the ſhape of a putrified Matter, why may not the alible Juice in like manner, being ſtrained by the Collander of the Glandula's, before it has indued the colour of Blood, go into a Milky Humour? This indeed ſeems more probable, becauſe, whilſt the Milk is carried from the Womb into the Breaſts, and on the contrary, paſſing through the Maſs of Blood, it is wont to ſtir up a perturbation through the whole, with a Feaveriſh Intemperance; beſides, in the firſt days, after the Birth, when the Glandula's do leſs rightly perform the Office of Secretion; Beaſts, who have not the Lochia, give a bloody Milk, which is drawn forth of their Udders, that is, mixt with Blood, by reaſon of the plenty of it flowing forth together.

Secondly, As to what belongs to the Menſtrua being ſuppreſſed, in the time of being with Child, and the Lochia plentifully coming away, after being Delivered, we ſay, that after the Conception of the Child, the Menſtrua ought to be ſuppreſſed by Divine Deſignation, for that the flowing of them often cauſes Abortion; then, becauſe the Veſſels are filled by a continual ſtilling forth of the alible Juice into the parts of the Womb, the Maſs of Blood doth not ariſe into ſwellings up, to be allayed by the Menſtruous Flux. For the ſame reaſon, Women for the moſt part, have not their Courſes ſo long as they give ſuck. Perhaps in ſome, indued with a more hot Blood, the monthly Courſes flow, both whilſt they are big-bellied, and in the time of their giving Suck, but that more rarely, and is wont not to happen without trouble; yet in the mean time, the Menſtrua being ſuppreſſed, during the time of being with Child, becauſe much leſs of the nutritious Humor is expended at that time for Milk, they much more deprave the Blood, than the ſame being reſtrained at the time of ſuckling the Child, are wont to do: yea, from them being long ſuppreſſed, in the former condition, an, as it were, envenomed taint is impreſſed on the Maſs of Blood, which, unleſs it be purged forth by the daily Flux of the Lochia, preſently after being brought to Bed, produces grievous, and almoſt malignant Diſtempers. Wherefore, that I may give my Opinion of the flowing of the Lochia, I ſay, that this Bleeding proceeds immediately from the Veſſels being broken, by which the After-Birth did ſtick to the Womb, and that by this way, the excrementitious Blood and Humors being partly heaped up about the Womb during the time of being with Child, and partly flowing from the whole maſs of the Blood, are evacuated, *viz.* whilſt the Womb at firſt intumeſied in its bulk, falls down preſently after the Birth, and is contracted into a leſſer ſpace, the Blood is plentifully preſſed forth from the Veſſels opening into it. But beſides, foraſmuch as during the ſuppreſſion of the Courſes, the bloody maſs is imbued with very fermentative Particles, aſſoon as after the Birth, the mouths of the Veſſels are opened, forthwith, as it were at the inſtant of a more large Flux of Monthly Courſes, the whole Blood grows hot (even as Muſt or new Wine upon the opening the Bottle) and endeavours to purge forth the highly fermentative particles out of its boſom, by the going away of the Lochia, as it were the flowring: And therefore, beſides the Blood, which in the firſt days oftentimes flows pure, by reaſon of the freſh opening of the Veſſels, afterwards is ſifted forth matter very much diſcoloured, *viz.* livid and green, and this very ſtinking. This kind of Flux is wont to continue at leaſt for fourteen days, yea, in ſome for a month; and if that by reaſon of any error, it be ſtopped before the maſs of Blood be throughly purified by ſuch flowring, preſently a Feaver, very dangerous, with horrid proviſions of Symptoms, is wont to be induced: of which we ſhall ſpeak anon in its proper place.

The third Conſideration, previous to the Doctrine of Feavers, belonging to Women in Child-bed, is chiefly about the Womb it ſelf; to wit, how it is affected after Child-bearing, and what influence it has on other parts of the Body. As to the firſt, there are chiefly two Accidents, upon which the acute Diſeaſes of Women in Child-bed very much depend, *viz.* Firſt, The falling down of the Womb, or the reduction of it, from the bulk of ingravidation, to its

natural

natural Site and Magnitude: Secondly, the ſolution of the unity, within its cavity, by reaſon of the breaking of the connexion, or tying to the Cake of it, or After-Birth. When the Child, with what wraps it about, is put forth, preſently the ſides of the Womb it ſelf, before very much amplified or enlarged, do mutually cloſe, and by the help of the Fibres, leiſurely contract themſelves into a narrower ſpace; by reaſon of this kind of contraction, the Blood and Corruptions, or Matter are plentifully preſſed forth from the Veſſels and Pores of the Womb, and are thruſt forth with the Lochia. But ſometimes it happens, by reaſon of ſome preternatural thing contained in the Womb, as part of the Secondine, or After-Birth, a Mole or piece of Fleſh, Clodders of Blood, *&c.* alſo, if there happen after a painful Birth, a Contuſion or great Dilaceration, that the Womb cannot rightly draw it ſelf together, but by an inverſe motion of the Fibres, aſcends upwards, and is lifted up into a bulk; alſo the membranes being affected with a Convulſion, it ſelf is ſtill tormented with Torments, as if it were yet in travel; which kind of Diſtempers, if they long continue, by reaſon of the Orifice of the Womb being tied together, with the Convulſive motion, the Lochia are oftentimes ſtopped alſo: from hence grievous Symptoms follow, and very often the Feaver is either firſt excited, or it happens, being for ſome other cauſe induced, to be rendred far more dangerous. Secondly, as to the ſolution of the unity, from the Cake of the Womb being broken, it comes to paſs, that the Birth, either at its juſt time, or precipitous, being too much haſtened; then the Secundine is caſt forth, either whole, or being torn, or pull'd away, part of it being left behind, it is cut off as it were in half. If the Child be born at its juſt time, and the Birth, with what enwraps it, comes away from the cavity of the womb, as ripe fruit from a Tree, whole, and without violence, the mouths of the Veſſels are ſomewhat unlocked, and the Lochia moderately flow; but from hence no grievous Symptoms is to be feared: but if the Child, not being yet ripe for the Birth, is pulled away, or breaks forth as it were by force, although the Cake, with the membrane is pulled away whole, yet the Veſſels being torn, a greater hemorrhage or bleeding, and at length an ulcerous diſpoſition follows, the little mouths of the Veſſels ſpewing forth a ſtinking matter. If that part, or the whole Secundine ſticks to the ſides of the Womb, , after the Birth, it there putrifies, and ſends forth very ſtinking matter or corruption, and ſtirs up wicked Diſtempers: oftentimes the Orifice of the Womb is ſhut up, and retains within gobbets of clodder'd Blood, little pieces of Membranes, or Fleſh, which putrifying, by reaſon of the heat, impoyſon the Blood and Humors, flowing together to that place, by Circulation, from the whole Body; alſo, by a troubleſom itching or provocation, they ſtir up the parts of the womb, being ſo very ſenſible, into Convulſions.

When therefore hurt is brought to the Womb from Child-bearing, after the aforeſaid ways, the ſame is quickly communicated to other parts, not without trouble to the whole Body; which thing indeed is wont to be done by a double means. For firſt, this happens, becauſe the Lochia being hindred from being thruſt forth, preſently reſtagnate or flow back upon the maſs of Blood, and infect it as it were with a virulent taint: moreover, from the contents putifying in the Womb, either the ſubſtance it ſelf of the Matter, or the Particles coming away from the cadaverous ſubſtance, are mingled with the Blood, and nervous Juice, paſſing through that place, and quickly infect their whole Liquors. Secondly, Hyſterical Diſtempers are more largely extended, by reaſon of the notable conſent, which happens between the Womb and the Brain, with the Fibres and Membranes of the whole Body, by the means of the nervous paſſage; for when the extremities of the Nerves, planted about the parts of the Womb, are driven into Cramps and Convulſive motions, by reaſon of the preſence of ſome hurtful humour, the Convulſions there received, preſently creep more largely upwards, by the endeavours and circumduction of the Nerves towards the Brain; and ſo it happens to the Viſcera to be ſucceſſively inflated, and cruelly haled together, and the Brain it ſelf at length to be pierced, and its functions to be as it were overwhelmed; hence from the convulſive motions, ariſing about the Womb, an inflation of the Belly and Hypochondria, a rumbling, vomiting, ſobbing, and ſtreightneſs of the Præcordia, difficult breathing, a ſenſe of choaking, and oftentimes a ſtupor, and want of Speech, or at leaſt ſome of theſe are excited: nor does the Tragedy ſo eaſily leave, but that alſo the Brain being hurt, by the continuance of the Diſtemper, by that means, the evil is retorted upon other parts, that oftentimes the whole nervous ſtock is compelled into irregularities of motions; for what commonly is ſaid to be done by vapors, and the Diſtemper, called the aſcent of vapors, creeping from the nether parts, to the upper, is nothing elſe than the parts of the Membranes and nervous paſſages, being ſucceſſively driven into Convulſions. Further, in theſe ſort of Diſtempers, the hurt action doth not always begin, or is at firſt perceived in that Region or Place where the hurt is inflicted, neither do the paſſions which are called hyſterical, proceed only from the Womb; for ſometimes the trouble is immediately brought from the Brain, or the convulſions and contractions begin in the extream parts, and ſometimes the extre-

extremities of the Nerves, ſomewhere in the Viſcera, as the Stomach, Spleen, Reins, no leſs than the Womb are haled; in which, irregularities being ariſen, they are continued into the neighbouring part, and from thence to the Brain; from whence again the Convulſions are reflected to other parts, and not ſeldom through the whole Body. Juſt ſo the buſineſs in Child-bearing Women, and with others in Feavers, as I have often obſerved; to wit, ſome by reaſon of their Womb being evilly affected, but others by reaſon of a Feaveriſh matter fixed in the Brain, by a critical metaſtaſis or tranſlation, fall into Paſſions like to the hyſterical. And theſe things being rightly præpenſed, concerning the prævious proviſion, in the Feavers of Women in Child-bed, there is not any thing that we ſhould ſtick at in the entrance more, ſo that we take notice that the bodies of Women lying in (eſpecially thoſe who are feeble, and of a more tender conſtitution) are debilitated, chiefly after a difficult and hard Labour; ſo that, by reaſon of this occaſion only, they eaſily conceive feaveriſh intemperatures, and being brought in by this or any other means, they are hardly able to bear them. We will next ſpeak of the Feavers themſelves, with which Women lying in, are wont to be ſick, of which Diſtempers there are commonly recounted as it were three kinds, *viz.* the Milky Feaver, the Putrid, the Symptomatic, or of that manner by a certain borrowed ſymptom, but is chiefly marked with the Pleuriſie, Squinancy, or the Small Pox: of which we will diſcourſe in order.

The Milky Feaver.

WE have already ſaid, that as yet it was uncertain of what matter Milk was immediately made, and by what paſſages it is carried into the Breaſts, moreover when this part appears not at all to anatomical inſpection, I am of the opinion, that the Milky Chyme, being made out of Aliments in the Bowels, and from thence confuſed to the Bloud for nouriſhing Juice, is preſently again, for the moſt part of it, ſeparated from its maſs by the help of the Glandula's in the Womb, or in the Breaſts, that it might ſupply the Child with nutriment, either in the Mothers Belly, or in her boſom by the Breaſts. In the time of going with Child, although the greateſt part of this is derived to the Womb, yet in the laſt months, a little quantity of it is laid up in the Breaſts; but about the third or fourth day, after being brought to Bed, the Milk is more plentifully carried into the Breaſts, and as it were with a certain force, that it quickly fills them to a ſtretching them forth, and begins to be troubleſom. At this time, Women lying in (though not all, yet moſt) are wont to be troubled with a feaveriſh intemperature, with thirſt, heat, and an inquietude of the whole Body, they complain of a pain very troubleſom in the Back and Shoulders, of a fulneſs and burning of the Breaſts: and unleſs the Milk be diligently drawn forth, it being too much congeſted or heaped up, oftentimes brings forth an Inflammation, with an Impoſthume following of it in the Breaſts. This Feaver, whilſt the Lochia are in good order, hardly laſts three days, but that about that ſpace it is wont to be allayed, a plentiful ſweating ariſing of its own accord; yet this intemperature being excited by the coming of the Milk, is ſomewhat increaſed and continued longer, if that the Milk entring the Breaſts in abundance, be not milked forth, but is again repelled from thence; for by its departure, as well as by its coming, a perturbation is wont to happen in the whole Body, with thirſt and heat, which alſo more certainly comes to paſs if it happens to be driven away violently, by repelling Topicks. But being driven by their help from the Breaſts, or departing of its own accord, it is thruſt forth, with the Lochia, in the form of a whitiſh humor, and a ſweat, or more plentiful tranſpiration, exterminates the Reliques of the Diſeaſe. If that with this kind of intemperance, brought in by reaſon of the commotion of the Milk, the Lochia be ſtopped, or errors in eating and drinking be committed, or any other evident cauſe ſhould happen, that may increaſe the fervor of the Blood, very often the Milky Feaver, preſently acquiring worſe Symptoms, changes into a Putrid or rather malignant Feaver.

The Cauſe, or formal Reaſon of the aforeſaid Feaver (whilſt the way of the Milk lies hid) may be only propos'd, from an Hypotheſis, and as it were a certain Augury; for being ſuppoſed, that this milky humor is carried to the Breaſts immediately, by a peculiar paſſage, from the Viſcera of concoction, without any commerce with the Blood, this feaveriſh Diſtemper ariſes, for that the Breaſts being filled with Milk, and greatly diſtended, the ſanguineous Veſſels are ſo compreſſed, that they do not eaſily tranſmit the Blood flowing thither; from whence, the Blood being hindred in its circuit, begins to tumultuate through its whole maſs, and the Spirits being inordinately moved, and wholly confuſed, it conceives a fervor, ſuch as being induced by a Stopping, Surfeit, Inflammation, or Wound, conſtitutes ordinarily the ſimple Synochus; but if the matter of the Milk (as it is not improbable) paſſes through the Blood, this Feaver of Women in Child-bed, ſeems to ſpring from hence,

that

that when this Latex is transferred to the Breaſts, having left the Womb, a great portion of it ſubſiſts in the maſs of Blood, which indeed, for that it exceeds the proviſion of the nouriſhing juice, and ſo cannot be wholly aſſimilated, and beſides abounds in heterogeneous parts, and as it were ſomething extraneous, and not mingleable with the Blood, creates a trouble, therefore for the carrying it forth of doors, and putting it forth, this three days feaveriſh Diſtemper is employed; For when the milky Chile, being uſed to be ſeparated about the Womb, by and by, after being Delivered of a Child, that wax of excretion is hindred, reſtagnating into the maſs of Blood, it is there firſt of all heaped up more plentifully, than that the whole may go into nouriſhment, or be received into the Breaſts: wherefore, the Milk, not only in its paſſage to the Breaſts, but alſo in its return towards the Womb, brings forth the Feaver, to wit, by reaſon of either paſſage thorow the Blood.

But however the cauſe of this Diſeaſe is ordained, it matters little or nothing towards the Cure; for this is wholly committed to nature, and ſo long as the Lochia are in good order, it proceeds for the moſt part happily, without any Phylical help, becauſe after the growing hot of the Blood, for three or four days, either a plentiful ſweat, or a more free tranſpiration, cures this Diſtemper, to wit, either the Particles of the Milky humor, degenerate in the aſſimulating, or the aduſt recrements, remaining after the deflagration of the Blood, or both of them at once ſupplying the food or tinder of the Feaver, are by little and little ſubdued, and evaporated out of doors, which being excluded, the Blood becoming free from the extraneous mixture, quickly recovers its priſtine condition; yet in the mean time, certain vulgar Rules are wont to be obſerved, about the admiſſion of the Milk into, or the driving away of the ſame, out of the Breaſts. If the Milk too plentifully ſprings into the Breaſts, that their inflammation, as alſo the immoderate growing hot of the Blood, may be prevented, at that time, a more thin and ſparing dyet, to wit, no fleſh broths, and alſo in a leſs quantity, is to be ordered: alſo the Breaſts are to be frequently drawn. If it be not commodious for the Mother to ſuckle her Child, it is uſual after the firſt or third day of her being Delivered to cover all the Breaſts over with Sear-Cloaths moderately binding (as the Plaiſter of Red-lead, &c.) for ſo the ſpongious ſubſtance of the Glandula's, is ſomewhat conſtrained, or cloſed together, whereby they leſs readily receive the milky humor flowing thither, yet this kind of Remedy ought to be cautiouſly adminiſtred, leſt if the Milk be wholly excluded, or driven out of the Breaſt too abruptly, reſtagnating ſuddenly in the Blood, it induces its diſorder, the prodromus or forerunner of the Putrid or Malignant Feaver: of which it remains that we ſpeak next.

The Putrid Feaver of Women in Child-bed.

WOmen Lying in, from the fault of an evil affected Body, as by the Contagion of a received Peſtilential Air, are found to bee too obnoxious to the Putrid, or rather Malignant Feaver; but all do not alike receive the Infection of this ſort of Diſeaſe; for poor people, Labouring Women, Country Women, and others accuſtomed to hard Labour, as alſo Viragoes, and Whores, which are brought to Bed clandeſtinely, bring forth without any great difficulty, and then, after a little time, leaving their Beds, return to their wonted Labours. But more rich Women, tender and fair, and moſt living a ſedentary life, as if participating after a more grievous manner of the Divine Malediction, bring forth in pain, and then preſently after the Birth they are ſubject to difficult and dangerous chances; the reaſon of which ſeems to lie in this, that thoſe who are uſed to much exerciſe, continually agitate and eventilate the Blood, and therefore fewer infectious taints from the monthly Flowers being ſuppreſſed, do gather together for the matter of a Diſeaſe; moreover, laborious and nimble Women, as they have their nervous parts more firm, therefore they are leſs ſubjected to convulſive motion, and to the paſſions commonly called hyſterical; on the contrary, in delicate, and idle Women, the maſs of Blood, in the time of their going with Child, becomes very impure and fermentiſible; beſides, becauſe they have the ſyſtem of the Nerves, and the Brain ſoft and weak, upon every light occaſion, they ſuffer diſtractions of the animal Spirits, and inordinate motions of the nervous parts And here, by the way, it is to be noted, that Women more than men, and that ſome of the ſame Sex before others, are ſenſible of the affections called hyſterical, not ſo much by the default of their Womb, as for that they are of more weak conſtitution of Brain, and nervous ſtock; for in thoſe ſo affected, the paſſions of anger, ſadneſs, fear, as alſo all troubleſome and more ſtrong objects, eaſily pervert the diſpoſitions and functions of thoſe parts, which when they are once hurt, for the moſt part afterwards, are accuſtomed to thoſe irregularities. But we will return from whence we have digreſſed. The Feaver but now propoſed, is wont to infeſt Women Lying in, indeed

at various times, and by reaſon of diverſe occaſions, now preſently after the Birth, eſpecially if it be difficult and laborious, now it ariſes in the firſt, now the ſecond, third, or fourth week; yet the ſooner it begins, the more ſafely it is wont to be cured. The Type or Figure of this Diſeaſe, is performed almoſt after this manner. After a previous indiſpoſition, an open feaveriſhneſs, for the moſt part with a ſhivering, or horror, conſtitutes the firſt aſſault, which is followed with heat, and afterwards ſucceeds a ſweat: perhaps, for a day or two, they have various reciprocal fits of heat and cold; then the Blood being wholly inkindled, the Lochia, if not before ſuppreſſed, either flow ſmally, or are wholly ſtopt: If the Diſeaſe be acute, and of a ſwift motion, it comes to its height on the third or fourth day, then an intenſe heat, with a very troubleſome thirſt, a vehement pulſe, and quick pertinacious wakings, a great inquietude of the whole Body, that they are continually toſſing themſelves in their Beds hither and thither, a thick Urine, and high coloured, and other moſt grievous ſymptoms, are wont to trouble them: whilſt the Feaver is after this manner at its height, no Criſis is to be expected; for I never ſaw this Diſeaſe cured by a critical ſweat, but that the buſineſs was ſtill very precipitouſly acted, as after the Blood was grown hot for a little time, preſently the aduſt matter being tranſlated to the Brain, moſt dangerous and heavy inordinations of it, and the whole nervous ſtock forthwith come upon them; for moſt often are ſtirred up, convulſive motions of the Tendons, wonderful diſtentions, and inflamations about the Viſcera, like to the hyſterical paſſions; then ſometimes, alſo follow a phrenſie, or delirium, not ſeldom a ſtupefaction, and ſpeechleſneſs; the ſtrength is ſuddenly caſt down almoſt in all, without any manifeſt cauſe, the Pulſe becomes weak, and unequal; and the ſick are ſuddenly precipitated to death; If that any perhaps eſcape, either by the returne of the Flux of the Lochia, or a Lask, coming upon it, they hardly recover but of a long time: I have known in ſome, purple ſpots to have appeared, and certainly in many, ſymptoms that reſpect either the Blood or nervous juice, which argue no light Malignity.

We will diſtinguiſh the cauſes of this Feaver, after the ordinary manner, into Procatartic, Evident and Conjunct. Thoſe of the firſt ſort, upon which the malignity, and the greateſt perniciouſneſs of the Diſeaſe depend, are two, *viz.* firſt, a depraved diſpoſition of the Blood, from the long ſuppreſſion of the monthly Flux. Secondly, after the Birth, the evil affections of the Womb, from the dangerous Labours of Women, (who undergo the Divine Malediction appointed them) from the Menſtrua being long ſuppreſſed, the Blood not only ſwells up, and its Sulphureous parts being too much carried forth, are rendered more apt for burning, but beſides, the maſs of the Blood is imbued with very fermentative Particles, ſo that (as hath been already hinted) as if it were touched with a venomous infection, preſently growing fervent, it is diſpoſed towards putrefaction, and corruptive diſorders; and beſides, forthwith impoyſons the nervous Liquor, and renders it infeſtuous to the Brain and the whole nervous ſtock. Theſe kind of evils, being impreſſed on the Blood, ought to be purged forth, by the Flux of the Lochia; but if after the Birth, the Womb be out of order, the Lochia are not only ſtopped, and ſo a purifying of all the Blood is hindred, but beſides, ſtinking corruptions or defilements, are thence beſtowed on the Blood, and grievouſly infect it: Alſo, by reaſon of convulſive motions, begun about the Womb, and from thence continued to other parts, inordinations are ſtirred up in the Blood and juices, which oftentimes conſpire, either the production, or the acerbation or growing worſe, of the Feaver.

The evident cauſes, which induce an actual effervescency, either to the Blood, having gotten an ill diſpoſition, or invert the vices of the whole Body to the Womb, are after a diverſe ſort. A painful Labour, a ſolution of the unity about the Womb, a bruiſe, a retention of preternatural things, an ulcerous diſpoſition, and very many other accidents, which are induced by a certain neceſſity, may do this. But the occaſions, that are at the diſpoſe of the Patients, and eaſily to be avoided, which are wont to excite this kind of Feaver, are chiefly two, *viz.* an ill manner of Dyet, and the taking of cold. It is an uſual thing, to give to weak Women, after being Delivered, on the firſt or ſecond day, the fleſh of living Creatures, or Broths made of fleſh meats, and other foods, very improportionate to their diſpoſitions, from whence preſently ariſe an indigeſtion, and great trouble in the Bowels, and a feaveriſh diſtemper in the Blood by reaſon of a more rich nutritious juice than ought to be. Beſides, the errors in Dyet, oftentimes hurt is cauſed, for that their Bodies, being ſo very tender, alſo by reaſon of the labours of the Birth, and bringing forth the Child, the paſſages are on every ſide opened, they are expoſed too heedleſsly to the cold: for moſt of them, being impatient of their Bed, within a day or two, or ſooner than they ſhould do, riſe out of it, and put on their Cloaths, from whence, preſently the Pores of the skin being ſuddenly contracted, and the Air being admitted into the parts of the Womb, tranſpiration is hindred, and often the Lochia, on the ſudden are ſtopped, either of which ſuffices to excite the feaveriſh diſtemper.

The

The conjunct cauſe, or formal reaſon of this kind of ſickneſs, chiefly comprehends theſe three things, to wit, there are preſent, firſt, a very notable diſcraſie of the Blood, that growing hot, from the Feaver being occaſionally induced, it doth not equally burn forth, nor leiſurely overcome the aduſt recrements, and afterwards critically thruſt them forth; but the Blood growing hot, is preſently looſned in its mixture, and its frame being unlocked, turns and declines towards corruption; hence, when it grows but a little cool, the ſpirits being ſhaken out of thier dominion, are moved into confuſion. In the mean time, the Sulphureous Particles become untamed, and fierce, wherefore, the ſtrength falls down without any manifeſt cauſe, the Pulſe is made weak and diſordered; after the deflagration of the Blood, altho the aduſt recrements are very much heaped up, yet nothing is rightly concocted or ſeparated, but the ſick being greatly oppreſſed in Nature, tho they continually ſweat, receive nevertheleſs oftentimes no eaſe from thence; but the feaveriſh matter, which ought to be thruſt forth, being tranſmitted into the head, and nervous ſtock, induces there moſt grievous perturbations of the animal regiment. Secondly, the Tragedy of this Diſeaſe owes no ſmall part of it, to the nervous juice being preſently made ſharp, and ſo improportionate to the Brain, and its Appendix; for this being infected, from the taint contracted from the Blood, doth not gently water, or pleaſantly blow up its ſubjects, but notably hale or pull thoſe tender parts, (as when an infuſion of vitriol is poured upon a Worm) and irritates or provokes them into convulſions, and into motions, as if of dancing or ſuddenly leaping forth, and ſometimes wholly overturns their functions; hence comes contractures, grievous convulſions, delirium, wakings, and ſometimes ſtupification, and the ſleepy Diſeaſe, upon Women Lying in. Thirdly, whilſt theſe things are done, oftentimes a third band of ſymptoms infeſt the ſick, to wit, for that the Womb, being hurt by ſome evil, moves it ſelf diſorderly, and is ſtruck with a Convulſion, according to theſe or thoſe parts, from thence by and by, convulſive motions invade, by the membranes, and nervous paſſages, the whole Region of the Abdomen; wherefore, the Viſcera and Hypocondria are blown up, belchings, and grievous vomitings are ſtirred up, then the Diſtemper creeping upwards, and poſſeſſing the nervous parts of the Thorax, a difficult breathing, and unequal, a palpitation of the heart, a ſenſe of choaking in the throat, by reaſon of the Muſcles being there drawn backward, and other ſymptoms, through the whole Body are excited, the ſame evil being at laſt carried to the Brain.

The Feavers of Women in Child-bed almoſt never want danger; but ſometimes it happens, about the beginning, that they are cured by a ſlender Dyet, and by the Flux of the Lochia being reſtored; but if the feaveriſh diſtemper does root it ſelf more deeply, that the whole Blood is inkindled, and immoderately grows hot, the Prognoſtick ought not to be eſteemed of a light Omen; and there will be a greater reaſon of danger, if beſides the heat being ſuffuſed all over, the ſick are troubled with a frequent ſhivering, if they are affected or moleſted with a great diſquietneſs, and wakings, with ſudden concuſſions of the Body, or a contracture of the Tendons: or if, Thirdly, they complain on the fourth days of a tingling of their ears, with a great repletion or fulneſs of the head, you may from thence collect the evil to grow worſe, *viz.* a tranſlation of the feaveriſh and hurtful matter to the Brain; nor is it leſs to be feared, if they have on them an oppreſſion, and weight of the *Præcordia*, that the ſick cannot breath freely, nor draw their breath deep, and from the bottom of their breaſt, but only from the top, and that frequently, and ſighingly, and that they move themſelves reſtleſly hither and thither: For this argues the Blood to ſtagnate in its circulation, about the Heart and Lungs, and alſo to be apt to grow into clodders, and to be coagulated, that if yet worſe diſtempers of the Brain and nervous ſtock follow, and the Pulſe ſhould become weak and unequal, you may pronounce the buſineſs almoſt deplorable; but if (as ſometimes tho it more rarely happens) after the Feaver being inkindled, and grievouſly threatning, either the Flux of the Lochia returns, or a Diarrhea with eaſe ſucceeds, ſome hope of health may be admitted, tho the ſame be at the laſt caſt.

Concerning the Cure of theſe kind of Feavers, there lies a very great task upon the Phyſitian, becauſe any Phyſick is eſteemed with the vulgar not only unprofitable, but alſo hurtful for Women in Child-bed; wherefore, Phyſicians are rarely ſent for, unleſs when there is no place left for remedies, and the opportunity of all profitable means be wholly paſt: If that perchance they ſhould be preſent, about the beginning of the Diſeaſe, it will not be eaſie to procure health to the ſick by vulgar Remedies, but whatever they ſhould attempt, unleſs it ſhould bring help, it would be ſaid by the Women, and others about the perſon, to be deadly and the only cauſe of her death; that in truth there is wont to happen to us, leſs of profit, or more of ignominy, about the Cure of no other Diſeaſe, as in this.

But the method of curing (even as in Contagious Diſeaſes) ought to be inſtituted twofold; to wit, Prophylactic or Preventive, and Therapeutic or Curative: The former of

theſe, delivers Precepts and Cautions, whereby Women lying, may be preſerved from the aſſault of Feavers: the other ſuggeſts curative intentions, whereby the ſick (if it may be done) may at length recover health.

1. Although this Feaver be ſomewhat Malignant, it is not caught by Contagion, and there is no fear of the ſicks receiving outwardly any invenomed taint; notwithſtanding, all Women in Child-bed have an innate mine of virulency, and from the evil of this, as it were the tinder of moſt high Malignity, they ought to beware; wherefore, they need an exact ordering, to wit, whereby after the Birth, the impurities of the Blood and Humors may be rightly purged forth, without danger of a Feaver; alſo, that the evil affections of the Womb may be healed, and that the ſtrength being broken and debilitated by the Labour, may be reſtored after its due manner. For theſe ends, theſe three things are chiefly to be inculcated, for preſcripts by Phyſicians.

Firſt, I judge it neceſſary, that a moſt exact manner of Diet be commanded to Women in Child-bed; to wit, that they be wholly fed with Oatmeal-Cawdle, made ſometimes of Beer, and ſometimes of Water and White-Wine mixt together, alſo with Panada, and other light Nouriſhers, for a week at leaſt; becauſe they are much emptied, therefore it may be lawful for them to ſup often, but nothing of ſolid or more ſtrong food is to be given. For I have diligently obſerved that theſe Feavers have been oftenеſt induced by the eating too ſoon Fleſh, or ſtrong Broths, or Food. Foraſmuch as Women lying in, ought to be handled, not only as thoſe that are grievouſly wounded, but as thoſe that have got a Feaveriſh indiſpoſition, from a diſturbed diſpoſition and temper of the Blood: For with them, the Blood being already too much carried forth, and as it were touched with an impure infection, moſt quickly catches Flame, by the acceſs or means of any Sulphureous thing.

Secondly, After Diet, the care will be, leſt the Pores be ſhut up, by the incautiouſly taking cold from without, or that the Lochia be ſtopped: for upon the leaſt occaſion, the manner of tranſpiration being changed, the Blood firſt growing hot, conceives diſorders; alſo the Womb being touched by the blaſt of Air, contracts it ſelf, and ſhuts up the mouths of the Veſſels, whereby the Lochia flow forth leſs: wherefore, for five days at leaſt, after being delivered, I would have Women wholly to keep their Beds. I know that it is a common cuſtom to raiſe them from Bed on the third day, but by that means I have known many that have fallen into Feavers; and in truth, if we deſire to keep Women in Child-bed from all danger, the ſafeſt means will be, that they may be kept long in their Beds.

Thirdly, Concerning Preſervation, the intent remains, that by cauſing a gentle provocation of the Blood in Women Lying in, the Flux of the Lochia may be continued; for this end, Midwives are wont (if after a difficult Labour they fear that Evil) to give them *Sperma Ceti*, or Powder of *Iriſh* Slate, or Saffron ſteep'd in White-Wine; moreover, to make them Oatmeal-Cawdle, that may more fuſe the Blood, of Water, and White or Rheniſh Wine mixed together, in which they boil, or in Poſſet-drink alſo, Marigold-flowers, Leaves of Penyroyal, or Mugwort; there are many other kinds of Adminiſtrations extant, about the ordering of Women in Child-bed, which being commonly known, I willingly paſs over here.

The Cure of the ſubſequent Feaver of Women in Child-bed, is far from the uſual method in Putrid Feavers: for in this, it is not to be expected, that the Blood being touched with a Feaveriſh burning, ſhould by degrees burn forth, and the ſame ſhould be ſeparated by a Criſis, but rather (as it is done in a Malignant Feaver) aſſoon as the Blood grows immoderately hot, it is convenient for it to be moved by gentle Diaphoretick Remedies, and its heterogeneous and impure mixtures to be carried forth of doors; wherefore, among the common people it is a cuſtom (and that not bad) to give to Feaveriſh Women Lying in, Sudorificks preſently; by this means, the Blood being eventilated, its effervency is allayed; alſo, by reaſon of its agitation, the Lochia apt to be reſtrained, are provoked into a Flux. There is great difference among Authors, from whence the beginnings of theſe kind of Feavers ought to be computed, *viz.* whether from the Birth it ſelf, or from the firſt ſenſe of growing Feaveriſh? However it matters little whether it be after this or that manner: For ſince this Feaver runs not the uſual ſtadia or courſes of the Putrid, neither hath a Criſis, nor wholly admits the uſe of Cathartic or purging Remedies, we need not be ſolicitous ſo much for the days, concerning its period and menſuration. But yet, as to the Curative Indications, it will be of uſe only to diſtinguiſh what is to be done in the beginning, increaſe, and end of this Diſeaſe: alſo, what we ought to endeavour whilſt there is ſome ſtrength remaining, as alſo what, when 'tis oppreſſed, and very much dejected.

When therefore any Woman in Child-bed is firſt taken with this Feaver, (whoſe aſſault is known from the Milky Feaver, becauſe for the moſt part it begins with a ſhivering) you muſt preſently let it be your work, that the more plentiful ſuſtenance may be drawn away from the burning Blood, and as I have already admoniſhed, that the fleſh of living Creatures, and

Broths

Broths made of them, be utterly forbidden; yet in the mean time, all cold things, and that are indued with a ſtiptic or binding virtue, are equally to be avoided; for theſe fix the Blood, and bind it too much, and hinder its very requiſite Purgation, both by the Lochia, and by tranſpiration through the skin. But rather, though the Feaver be urgent, give them Decoctions, Powders, and Confections of things moderately hot, of which ſort are (as is already ſaid) Decoctions, or diſtilled Waters of the Flowers of Marigolds, the Leaves of Penyroyal, Mugwort, the Roots of Scorzonera, alſo Bezoartic Powders, Spirits of Harts-horn, fixed Salts of Herbs, *&c.* If the Lochia ſhould be ſtopt, that their Flux may be again provoked, muſt be endeavoured every way: To the moving of this, conduce Frictions and Ligatures about the Thighs and Legs, ſometimes Cupping-Glaſſes, or Bliſters about the Thighs or Hips, alſo in the Soles of the Feet; alſo, ſometimes the opening of a Vein in the Ankle, is convenient; in the mean time, a Fomentation of the Hyſterical Decoction, is to be applied about the Pubis, or the Caul of a Weather or Sheep taken out warm, may be laid to the bottom of the Belly; and experience manifeſts, that ſometimes Injections into the Womb are profitable: If the Belly yields not, it may be gently brought down, with a Violet Suppoſitory, ſo called, or an emollient Clyſter; of more ſtrong provocations you muſt take heed, becauſe in Women Lying in, even as in a malignant Feaver, from a copious dejection, with loſs of Spirits, Life is quickly loſt. If with the ſuppreſſion of the Lochia, there be a notable perturbation of the Blood, with Vomiting, thirſt, and wakings, I have often known Laudanum mixt with Saffron, given with happy ſucceſs. Inſtead of a cooling Julep, this kind of mixture is convenient, *viz.* Take of Water of Penyroyal and Balm, each three ounces, of Hyſterical Water two ounces, of the Syrup of Mugwort three ounces and an half, of the tincture of Saffron two drams, of Caſtor ty'd in a Rag, and hung in the Glaſs, one ſcruple, mingle theſe, and let them drink of this three or four Spoonfuls oftentimes in a day.

2. If notwithſtanding the uſe of theſe Remedies the Feaver grows worſe and worſe, and by degrees is increaſed with worſer Symptoms, that beſides the diſorders of the Blood, the Brain and nervous parts begin to be touched, Medecines, though many of every kind may be tried, do little; yea, in this caſe the indications are almoſt the ſame with thoſe made uſe of in the Plague it ſelf: foraſmuch as the Lochia being for a good while ſuppreſſed, they cannot eaſily be reduc'd, or ſcarcely at all, in the great confuſion of the Blood and Humors; therefore it is convenient quickly to move a Sweating, to wit, that the corruptions impreſſed on the Blood and nervous Juice, and reſtagnating from the Womb, may be carried forth ſome how, by ſweat and inſenſible tranſpiration. Therefore here, Powders, and Confections of Bezoar, Spirit of Harts-horn, or of Soot, Tinctures of Corals or Pearls help. I have ſometimes ſeen, by the help of theſe kind of Medecines, in a deſperate caſe, when the Pulſe, and other ſymptoms have appeared a little better, ſome ſmall hopes to ſhew themſelves; yet Cure rarely to follow: but when the uſe of theſe Cordials were left off, the ſick with a weak pulſe, and a Looſneſs preſently ariſing, have been precipitated to Death.

3. When yet the buſineſs of the ſick proves ſtill worſe, when the Feaver being increaſed, the pulſe is weak and unequal, and frequent horrors, and convulſive motions in the whole body, with a delirium and ſtupefaction infeſt them, then the Phyſician having firſt made a prognoſtication of Death, may inſiſt upon a few Remedies, and thoſe only Cordials, and muſt wholly abſtain from Blood-letting, Scarification, Bliſtering, or the uſe of Cupping-glaſſes; for ſuch adminiſtrations beget only an odium or blame, that by ſo doing, we are eſteemed by ſome Women, as wicked and cruel.

The Symptomatic Feavers of women in Child-bed.

THE Acute Diſeaſes of Women in Child-bed, ſhew themſelves not only according to the Figure of the aforeſaid Feaver, but ſometimes they are beſet with ſome ſignal ſymptoms, to wit, the Squinancy, Plurilie, Inflammation of the Lungs, Dyſentery, Small Pox, or of ſome other kind; and at that time, they get the appellations of thoſe Diſtempers. It will not be here ſeaſonable to repeat at large what belongs to the Eſſences and Natures of each; but I ſhall briefly ſhew what theſe ſickneſſes, being complicated with the Diſtempers of Women lying in, contain peculiarly, as to the Cauſes or Cures.

All theſe Symptoms, we ſuppoſe to proceed from a certain coagulation of the Blood, and from thence its extravaſation; But whilſt the Blood is extravaſated, or put forth of the Veſſels in one part, its efflux, however natural and critical, is hindred in another: wherefore it is dangerous, leſt whilſt the Blood begins to be coagulated, either in a particular or accuſtomed neſt of Coagulation, or univerſally in its whole maſs, the flowing of the Lochia be ſtopped,

which

which in truth for the moſt part happens, and therefore theſe Diſtempers, for the moſt part, are deadly to Women in Child-bed; yet the Cauſe of their Death, for the moſt part, happens with ſome difference, *viz.* in the Small-pox, the flowing of the Lochia draws inwardly the malignity, begun to be carried forth outwardly, and forthwith compells the maſs of Blood, and the Heart it ſelf to be empoyſoned with its evil; and therefore in the Small-pox, theſe purgings of the womb are convenient to be ſtopped; but in the Pleuriſie, Squinancy, and the reſt, when the provocative of the Diſeaſe being fixed here or there, in a particular place, draws to it ſelf the impurities of the Blood, which ought to be ſeparated or ſifted forth by the Lochia, and derives it ſtreight from the Womb, for that reaſon it increaſes the impurity of the Blood. The Lochia being ſtopped in the Small pox, by the more univerſal manner or way of excretion, may be ſhut forth of doors, with the venomous particles of the Diſeaſe, which thing indeed does not ſucceed in the reſt, by reaſon of the minute, and more ſparing manner of excretion.

Of theſe, the Squinancy, Pleuriſie, and Inflammation of the Lungs, by reaſon, both of the great ſimilitude of the Cauſe, and analogy of the Cure, may be conſidered together; when any Woman lying in is diſtempered with any of theſe, it is to be ſuppoſed, that beſides the infection gathered together in the time of being Big-bellied, there happens a certain ſowriſh diſpoſition of the Blood, by the means of which, whilſt that it ſelf grows feaveriſhly hot, certain Particles of it, being fuſed with the Sowrneſs, enter into congelation, in this or that part, like Milk growing ſowr, and then to be coagulated: The Blood being there frozen or congealed, and hindred in its circuit, ſtops the paſſage of the reſt; but the Blood being obſtructed in its motion, buts againſt the impediment, and ſo being heaped up about it, and driven forth of the Veſſels, grows into a tumor: from thence preſently, whatſoever is contained in its maſs, that is heterogeneous, and to be ſifted forth, is laid aſide into the diſtempered part, as it were a ſink: wherefore, the corruptions of the Blood, that ought to be purged forth by the Womb, are derived from thence towards the neſt of this Diſeaſe, which, when they cannot be ſufficiently purged forth by this way, both more remarkably corrupt the Liquor of the Blood, and render the particular diſtemper, *viz.* the Squinancy, Pleuriſie, or any other more hard to be cured.

For the Cure of theſe kind of complicated Diſtempers, preſently from the very beginning, it ſhould be endeavoured, that the Blood being fixed ſomewhere, and begun to be extravaſated, may be reſtored to Circulation, that it may not impoſtumate; becauſe, very rarely, Women lying in, are cured of theſe Symptomatic Feavers, by an Impoſthume, or ſpitting forth of the corrupt Matter: wherefore, internal Remedies, which fuſe the Blood, and free it from coagulation, are to be made uſe of; of which ſort are chiefly Diaphoretics full of volatile Salt, as Spirit of Hart-horn, Soot, Urine, alſo the Salts themſelves; in like manner, Shelly and Bezoartic Powders, Lapis Prunellæ, Decoctions and Juleps of Vegetables provoking Urine, or the terms, with all which ought to be mixed, what by experience are found proper for the diſtempers of the Womb: Beſides, diſcuſſing Remedies, which may drive away the impacted matter, and diſperſe it (of which ſort are Liniments, Fomentations, and Cataplaſms) are diligently to be applied. In the mean time, the more impetuous motion, and immoderate effervency of the Blood, are to be removed, and its purgings, by all the wayes poſſible transferred to the inferior parts. For this end Frictions, Ligatures, Epiſpaſtics, and (if need be) Scarifying about the Feet and Legs, are to be adminiſtred; if the diſtemper very much growing worſe, a taking away of Blood be indicated, unleſs there be a great fulneſs in the whole Body, and a very acute inflammation in the diſtempered part; it will be beſt to open a Vein in the Foot, or to take away Blood from the hemorrhoid Veins by Leeches: But if neceſſity urges, it may be done in the Arm it ſelf, if after that Letting Blood (if another be admitted) let it be done in the Leg; but you are to be warned, that in theſe caſes, the opening a Vein is to be ordered very cautiouſly, for unleſs it brings preſent help, (which I have rarely known it to do) immediately the Pulſe being made more weak, the buſineſs of the ſick becomes much worſe.

The Dyſentery takes its riſe almoſt for the like cauſe, with the aforeſaid diſtempers; but in this, becauſe the extravaſated Blood is preſently poured forth, nor being retained in the Body becomes there troubleſome, or is any more corrupted, and as this Flux makes an excretion near the Womb, and does not afterwards drive it to any other place, there is leſs of danger to be feared, from this Diſeaſe, than from thoſe aforeſaid: yet oftentimes this Diſeaſe, is fatal to Women in Child-bed, for that indeed, the rather, becauſe things attempering of the Blood, and moderately binding, are ordered for the Dyſentery: for theſe are found too apt to inhibit the Flux of the Lochia; wherefore in this caſe, until the Women Lying in are ſufficiently purged by a long Flux, the Cure of the other Diſeaſe is to be omitted, and the fiereeneſs of the ſymptoms is to be allayed, only with gentle aſſwaging things.

The indications of the Small Pox, do not only differ from thoſe above deſcribed, but indeed

they

they are beſet with contraries to themſelves; for they require (as hath been ſaid) that the Flux of the Lochia ſhould be moderately ſtaid: yet in the mean time, that the flowring forth of the Blood, and a gentle ſweat ought to be continued; for when in this Diſeaſe, the invenomed ferment is twofold, and the corrupt Particles of the Blood, are carried outwardly in a twofold way, you muſt beware, leſt that the leſſer, and ſtraiter part, ſhould draw to its door, the whole matter, or more than it were able to ſend forth: therefore, leſt the Lochia flowing more plentifully, ſhould recall inwardly the venom, apt to flower outwardly, the manner or way of Dyet is ſomewhat to be changed, and eſpecially thoſe things which have a poyſon reſiſting force, and are alſo aſtringent (as the roots of Tormentil and Biſtort) are to be boyled in the Broths of the ſick; alſo Powders, Juleps, and Opiats, indued with ſuch like virtue, are convenient to be adminiſtred at due intervals, yea, in this caſe, by no means, Women ſhould be indulged, that they might eat fleſh, or Broth made of it, or to riſe out of their Bed: but the quiet, both of mind and Body, is to be procured, as much as may be, and a Dyet to be ordered of thoſe things, that move not the Blood, and the buſineſs almoſt wholly to be committed to God and Nature.

What hath already been ſaid, concerning the acute Diſeaſes of Women in Child-bed, may eaſily be illuſtrated with Hiſtories and Obſervations: But examples which may be brought in this thing, for the greateſt part, are mournful and of an ill chance: becauſe thoſe Feavers for the moſt part end in Death. But to deſcribe theſe kind of ſickneſſes, does neither confirm the work of the Phyſitian, nor render approved the method of Medicine, altogether taken in them; however, becauſe the knowledg of theſe may make for the better diſcovery of this Diſeaſe, I ſhall here propoſe ſome ſingular caſes of Women Lying in, and variety of ſymptoms; in which, altho the forms and means of Cure more ſparingly occur, yet we may have ſome rules of precaution, of no contemplable uſe.

A Gentlewoman in her ſix and twentieth year of her Age, brought forth her ſixth Child, with very difficult Labour, and not without danger of her Life; yet preſently after, ſhe began to be better; on the ſecond day ſhe eat a whole Chicken, on the third roſe out of her Bed, and ſate in a Chair for four hours; the night following ſhe found her ſelf ill, at which time her Milk came into her Breaſt; which, by the application of Diaculum Plaiſters, ſoon vaniſhed; the next morning ſhe complained of a wearineſs and as it were an ulcerous pain of her whole Body, alſo of a vomiting, nauſeouſneſs, and fulneſs about the Ventricle, and Hypocondria: the following night was full of trouble; on the fifth day ſhe was plainly in a Feaver, ſhe felt now a ſhivering, now a heat, every where increaſing, ſhe nauſeated every thing, and was troubled at her Stomach; moreover being unquiet, and without ſleep, the Lochia flowed little, but a whitiſh humor (commonly called the Flux of the Milk) came away: In the evening ſhe had a weight, and as it were a ſleepineſs about her forehead and temples, and began to ſleep a little; but awaking in half an hour, being diſturbed with Phantaſms, ſhe complained of her head, as if increaſed in bulk, alſo of her jaws being ſet, that ſhe could not open her teeth, and her fiſts being ſtrongly clutched, ſhe ſeemed as if ſhe felt a pricking and ſtupor, or numneſs in her whole Body; her Ventricle and Hypochondria ſtood ſtill inflated, and ſtretched forth; they adminiſtred to her Frictions, Ligatures, Cupping-glaſſes, and other Remedies, both inward and outward, that might recall the Lochia, and drive the recrements of the Blood from the head: Her Pulſe being weak, and diſordered, would not admit of Letting Blood; Powders, and Juleps, which might gently move ſweating, and fuſe the Blood and nervous juice, and hinder them from reſtagnating, were diligently given her; yea, fomentations, now of Woollen Cloaths dipped in emollient Decoctions, and now of warm inwards of living Creatures, were applied to her Belly; in the mean time, ſtinking things (ſuch as they uſe to the Mother Fits) were put to her noſe, which might drive away the impetuouſneſs of the Spirits and Blood, carried into the head, but theſe, and other things, being for ſeveral hours carefully performed, ſhe ſeem'd to feel ſome eaſe; but ſtill ſhe feared to ſhut her eyes, or to ſettle her ſelf to ſleep, for her eye lids being cloſed, a thouſand Phantaſms ran in her mind, with noiſe and tingling in her whole head: ſhe continued that night almoſt without ſleep; aſſoon as ſhe had begun to ſleep, preſently being affrighted, and feeling a weight in her Precordia, ſhe was awaked: on the ſixth day about noon, ſhe was troubled with a great ſhivering, or rather a horror, with a ſtrong concuſſion of the whole Body; to which, as in the fit of an Ague, by and by heat, and then ſweat copiouſly followed: but from thence, nothing of eaſe accrued to the ſick, for preſently after the ſweat, the feaveriſh heat was renewed, and convulſive diſtempers infeſted her more: the night following, with the reſt of the ſymptoms growing worſe, firſt a Palſie was excited in her tongue, and by and by in her throat, that ſhe could not ſpeak, and ſcarce ſwallow at all: on the ſeventh day, about the ſame hour, a ſhivering invaded her again, with heat and ſweat; then her Pulſe being much weaker, and unequal; alſo a difficult breathing, and fetching the breath ſhort and quick, with her Breaſt lifted up, ſhe knew not them about her: on the eighth day ſhe died.

There

There was a manifold occaſion of the death of this Gentlewoman, prediſpoſed to a Feaver, by reaſon of her Big-belly, and which had increaſed the malignity of the Diſeaſe over and above; for the hurt received by her hard Labour, the ſudden excluſion of the Milk from her Breaſts, the eating of fleſh, and the riſing too ſoon out of her bed, happning together made, as it were a conſpiration for the greater evil: The Blood being touched with a feaveriſh burning, preſently conceived inordinations, and ſnatched into it ſelf the Lochia, and perhaps other defilements of the Womb, and ſo by that means acquired a greater infection, and plainly venomous diſpoſition; the membranes of the Viſcera, being imbrued with the degenerate nervous juice, were ſtruck either with Convulſive motions, or with Convulſions continued to them from the Womb; for theſe kind of inflations, about the Abdomen, and thoſe diſtentions are the effects of Convulſions: For altho the direct Fibres drawing the member, do oftentimes preſs it, yet ſince the Fibres are direct and tranſverſe, and others placed in a various ſite, the membranes are pulled together into an hollowneſs, by their coming together, the part ſwells up like a blown bladder, into whoſe vacuity the Air being rarefied ſecondarily carries it ſelf forward: But it is not the Air (as is commonly ſaid) or a blaſt there at firſt heaped up, that is the cauſe of the diſtention. The Blood growing hot in our ſick perſon, and being quickly filled with an aduſt and malignant matter, did endeavour to ſubdue it, and being unable to put it forth by ſweat, forthwith fixed it in the Brain; the firſt ſuffuſion of the ſame matter into the head, by reaſon of the animal Spirits being half overthrown, brought in that ſenſe of her head being much increaſed in bulk; which thing happened by the like means as when the foot being taken with a ſleepineſs, ſeems as if it felt much bigger then it is: But that after ſome eaſe, the diſtemper grew worſe, by ſleep and cloſing of her eyes, the reaſon is, becauſe waking, and the exerciſe of the ſenſes, ſhake off and remove from them, ſomewhat, the matter beſieging the Brain and Nerves; which notwithſtanding being neer and in its precincts, ſleep creeeping on, is as it were ſupped up by them, and enters their Bodies more deeply with the alible juice. But the Blood, altho it had plentifully poured forth its recrements in the Brain, yet did not it ſelf become free; but being ſtill full, with an impure ballaſt, it conceived as it were a critical flowring, and attempted to ſhake off its burthen once or twice (as it is wont in a great excretion) with a ſhivering and with heat and ſweat following it, by which endeavour however nothing was further effected, than that the matter ſticking to the Brain, pierced more deeply into it, and becoming fixed in ſome little ſhoots of the Nerves, took away her ſpeech and ſwallowing, and afterwards her ſenſes; and the maſs of Blood, being by degrees more and more depraved, at length became unable to ſuſtain Life.

A NobleGentlewoman, being married a little before ſhe was twenty years of Age, and being with Child, uſed, during the time, an ill dyet, and little or no exerciſe; yet falling into Labour, and ſuffering the torments with intermiſſion, and frequent eaſe for twelve hours, at length was brought to Bed of a Son: The Child, with the after-birth came away, and all things were right about the Womb: the firſt and the ſecond day ſhe found her ſelf indifferently well, but on the third, after a light ſhivering, ſhe began to complain of thirſt and heat; to which a looſneſs followed, that ſhe had that day four ſtools: the following night ſhe was almoſt without ſleep, the feaveriſh diſtemper remained, after that in the ſame manner for two days; daily ſhe purged three or four times; the Lochia as yet flowed moderately: when on the ſixth day, by the perſuaſion of the Women, ſhe had took ſome aſtringent thing, to moderate the Flux of her Belly, the purgings of the Womb were almoſt wholly ſtayed: at which time the Feaver became more ſtrong, and ſymptoms as it were hyſterical, appeared; for in her Precordia, ſhe had great and frequent oppreſſions, and was troubled with a ſenſe of choaking in her throat; on the ſeventh day, the heat was yet ſtronger, and her breathing difficult and laborious; but then, by the preſcription of a Phyſician, at that time firſt ſent for, Blood was taken from her foot to three ounces, by which ſhe was better for four hours; for a quiet ſleep, with a plentiful ſweat followed upon it, and the Lochia appeared again tho in ſmall quantity: In the Evening again, all things grew worſe, her ſtrength being very much loſt, her Pulſe weaker and unequal; ſhe complained alſo of a noiſe and tingling of her ears, with a fulneſs of her head, moreover a leaping up of the tendons in her wriſts; alſo ſhe had ſudden concuſſions of her whole Body, yet ſtill her looſneſs held; to her were adminiſtred, by the preſcripts of ſeveral Phyſicians, Cordials, and other Remedies, and kinds of Adminiſtrations carefully, but nothing profited, her Pulſe being more weak, and her ſtrength leiſurely waſting, ſhe died on the ninth day, after ſhe was delivered.

This Feaver very much depended upon the vitious proviſion of the Body, as the pocatartic cauſe; for I have often obſerved, that it fares ill with Women Lying in, who when Big-bellied devoured fruit, and any unwholſome traſh, and living without motion or exerciſe, indulged themſelves with eaſe and reſt: the Blood, by reaſon of the previous Cachexie, conceived a burning without any evident cauſe, as it were of its own accord: But growing hot laying

ing

ing inwardly ſtill its recrements, and impurities, cauſed the Diarrhea: neither yet was its maſs made more pure, by its almoſt continual excretion, yea rather being ſtill more depraved in its mixtion or craſis, the blood at length wholly departed from its proper diſpoſition, and became unable to be fermented in the heart, whereby heat and breath might be every where diſperſed: The looſneſs, excited by the motion of Nature, was untowardly ſtopped, eſpecially by the uſe of aſtringent things; for this I have often obſerved, never to be done without paying for it; becauſe the Flux of the Belly has cured ſome that have been ill, but in this Lady, and in many others (as has abundantly appeared to our Experience) altho it did not take away the Feaver, yet it freed her from the more grievous Diſtempers of the Brain and nervous ſtock: from whence this ſick perſon was wholly free from a Delirium, nor was ſtruck with Convulſive motions, till reduced almoſt to extremity.

The Mother of a Family, and a Gentlewoman about 36 years of Age or upwards, being with Child of her ſeventeenth Child, was troubled, and very anxious, leſt ſhe ſhould die of that Child-bearing: But (God favouring) ſhe was delivered well enough of a Son, and for three days after ſhe was very cheerful: on the fourth day, when ſhe had eaten more than ſhe ſhould do of a Chicken, a little before night ſhe fell into a feaveriſh Diſtemper, with vomiting and a ſtopping of the Lochia: all night ſhe lay reſtleſs and without ſleep, the next morning ſhe had four ſtools, and ſeemed ſomewhat eaſed: about Noon (about which time I came to her) ſhe complained again of heat and thirſt, as alſo a palpitation of the Heart, and of the aſcent of ſome ſubſtance in her throat; her Pulſe was quick and ſmall, her Urine red, the Lochia ſcarce appeared: I ordered her Juleps, Cordials, and things to purge the Womb, beſides a fomentation for the bottom of her Belly, alſo her Legs and Feet to be rubbed often, with warm woollen Cloaths; at going to ſleep I gave her of Laudanum one grain, with Saffron Powder half a ſcruple, in a ſpoonful of Treacle-Water: She ſlept well, and the Lochia came down plentifully, and by that means, with a ſlender Diet, and continuing to provoke moderately the Flux of the Womb for a few days, ſhe became very well.

The immoderate eating of Fleſh, as an evident and almoſt only ſufficient cauſe, without any great proviſion, or vicious prediſpoſition, induced the Feaver. The Lochia reſtagnating into the Blood, increaſed its intemperance, and preſently brought troubles upon the nervous kind; but in the mean time, the Blood altho growing hot, did not undergo any great corruption, but when the Recrements, heaped up by the Surfeit, were ſent forth by the Looſneſs, and the Blood, the Lochia being reſtored, began to be purged forth again after its wonted manner, this Feaver wanting a further malignant Ferment, quickly vaniſhed.

A Noble Lady, young and fair, was brought to Bed of a ſecond Child, and for ſix days, as to the Lochia and other Accidents, ſhe was well, and wholly free from the ſuſpition of any intemperature, ſhe ate fleſh daily, and riſing from her Bed, was brisk and chearful in her Chamber: on the ſeventh day, without any manifeſt cauſe, a ſhivering came upon her, with a Feaver, and a leſſening of the Lochia, but not ſuppreſſed: to the tenth day after her Delivery, ſhe was only moderately feaveriſh; whilſt the purgings of the Womb yet flowed, ſhe remained free from any grievous Symptom: but then, although ſhe was greatly feaveriſh, ſhe was more chearful than ordinary, and ſeemed more confident of her health: At Night ſhe ſlept little or nothing; the Morning following (at which time I firſt viſited her) ſhe clearly raved, the Lochia were ſtopped, alſo her whole Body was ſhaken with horror, the tendons of her Wriſts were pulled together, ſo that I could hardly diſtinguiſh her Pulſe, which in the mean time was weak, unequal, and very quick. I ſaid ſhe would die quickly, unleſs God ſhould miraculouſly reſtore her by his Divine Power; however, ſix grains of Oriental Bezoar being given her in a ſpoonful of Cordial Julep, brought upon her a plentiful Sweat, with a better Pulſe; then other Cordials being given, with due intervals, gave ſome little hopes, tho I doubted they would not continue: after four hours from the time that I came, the ſick Lady had of her own accord a great Stool, and preſently her ſtrength wholly failed her, and within half an hour ſhe died.

When there happened nothing of ill to this Lady, as to her Delivery, or Womb, ſo pernicious a Feaver, and ſo ſuddenly mortal, could not happen without a great and malignant procatarſis of the Blood and Humors; whether a more full Diet, or taking Cold, or any other evident cauſe, gave a beginning to this, is uncertain; becauſe, the Women and Nurſes helping her, knew of no manifeſt occaſion of her Sickneſs: The Feaver being inkindled, the infection of the Blood could not be wholly carried away, by the purging of the Womb, tho long continued; tho for that reaſon, the more cruel Symptoms came not preſently upon her, yet the Evil ſtill lurked within, and the Diſeaſe being very acute, ſhewing it ſelf with a ſwift motion on the fourth day, when Nature ſhould have endeavoured a Criſis, the matter of the Feaver being moved, but not overcome, as it were in a moment overturned at once, the Brain and nervous parts, whence Death was to be expected, and ſuddenly followed.

A Woman well known, who had ſcarce paſſed the twentieth Year of her Age, of a florid Countenance, and ſlender Body, after her being brought to Bed, when the Lochia flowed im-

moderately, made uſe of ſome aſtringent Remedies, by the counſel of thoſe about her, by which means they were wholly ſtopped; but a Flux of her Belly ſucceeded, which when it had increaſed for three days, the Women gave her other things for the ſtopping her Looſneſs: nor were they fruſtrated in the ſucceſs; in the mean time, in the place of the former evil, they had brought a moſt dangerous Feaver, and diſtempers as it were hyſterical; for the unhappy Gentlewoman Lying in, was troubled with thirſt, heat, wakings, and at ſeveral turns, with ſwoonings, and cold ſweats; at this time being ſent for, I preſcribed her Cardaic Remedies, and ſuch as moved the purgings of the Womb, and alſo a Clyſter to be given her: at length, the Flux of her Belly being provoked, the Lochia alſo came down, and the ſick Woman being freed from the aforeſaid ſymptoms, and the more grievous Diſeaſe, to wit, the Remedies of the Nurſes, quickly grew well of her Feaver.

The more plentiful Flux of the Womb, hapning to this Woman, removed the Procatartic cauſe of a more grievous Diſeaſe: wherefore, when they had committed ſo many errors about the ordering her, (*viz.* firſt in ſtopping the Lochia, then what might compenſate their defect, in hindring the Flux of her Belly) yet the Feaver was only light, and without any venomous taint impreſſed on the Blood; the like to this I have known to happen frequently, to wit, when at firſt the purgings of the Womb have flown very plentifully, afterwards when they have flown very ſparingly, and ſometimes ſtopped, the Women in Child-bed have eſcaped. And by the way, it is here to be noted, that it is wholly dangerous, to inhibit, or at leaſt divert, and croſs any motion of Nature, incited, tho' irregular.

A Noble Gentlewoman, about Twenty Years of Age, indued with a ſmooth and full habit of Body, miſcarried twice in the ſpace of a Year; when ſhe had again Conceived, by the preſcription of her Phyſician, ſhe provoked a Vomit once a Month, by drinking plentifully Poſſet-Drink, by which ſhe was wont to caſt forth much thick tough Phlegm; alſo in the time of her being with Child, he let her Blood five times; the time of her going being over, ſhe was brought to bed of a Son, with very hard Labour; the Secundine came whole away, and ſhe purged notably: on the ſecond day, whilſt ſhe was lifted upon her feet in Bed, that the Sheets and the Blankets might be laid in better order, ſhe took cold, and by that means the bloody Lochia wholly ſtopped, and only a little ſerous Water came away: on the third day ſhe began to complain of an acute pain in her right ſide, to which the Women laid Bags of Camomil made hot with Bricks, but the diſtemper grew worſe with a bloody ſpittle; on the fourth day of her being brought to Bed, a moſt ſharp pain, with a difficult breathing, and very laborious, invaded her: by the preſcription of her Phyſician, then coming to her from the neighbourhood, ſix ounces of Blood was taken away, out of the Baſilic Vein, and ſhe felt ſudden eaſe; for ten hours ſhe was better, in the middle of the night the pricking pain returned with its wonted fierceneſs: at length, other Phyſicians being called to Counſel, they agreed that it was neceſſary to open a Vein again, in the Arm of the diſtempered ſide: four ounces of Blood being taken away, the pain remitted, and the ſick breathed better; then by Diaſphoretic Remedies, ſhe fell into a great ſweat, with a quiet ſleep: But the Pulſe was made quicker and weaker, alſo contractures of the Tendons in her wriſts appeared: preſently afterwards ſhe talked idly, and within twenty four hours, after ſhe was laſt let Blood, ſhe departed.

That this Lady fell into a Pleuriſie, with a Feaver, upon the Lochia being ſuppreſſed, the cauſe in ſome meaſure ſeemed to be, the letting of Blood ſo often in the time of her being with Child: for by this means, the Blood being accuſtomed to be eventilated at the Arm, afterwards growing hot, leaving the Womb, was carried violently towards the place of its letting forth, where, when it found not a paſſage, it fixed in the neighbouring ſide, as the next neſt to the place of extravaſation; yea, beſides the uſual manner of a Pleuriſie, there was no ſmall malignity hapned to this Diſeaſe; for the Blood being hindred from being let forth of the Veſſels, began preſently to be corrupted in its diſpoſition, and in the third day of the Feaver, was ſo much depraved, that it could not be any longer fermented in the heart ſo as to prorogue life.

It was not ſo with the Wife of a certain Smith, who was brought to Bed, at what time her Children had the Small Pox in the ſame Houſe, and ſhe her ſelf, as it ſeemed, had taken the Contagion of the ſame Diſeaſe, for on the ſecond day after her Delivery, they began to break forth with a feaveriſh heat, and pain in her Loyns, which indeed for three days, whilſt the Lochia moderately flowed, aroſe rightly into little ſwellings; altho' the purging of the Womb was very copious at that time, ſhe had the Small Pox very thick all over her Body, not only in the ſuperficies of her skin, but alſo they filled the cavity of her mouth and throat, ſo that ſhe could ſcarce ſpeak or ſwallow: The ſixth day of her Lying in, the Lochia flowed immoderately, from whence preſently fell upon the ſick, a frequent ſwooning, with a flagging of the Small Pox, Convulſions, and other ſymptoms of an ill nature, which threatned Death ſoon; being ſent for, I preſcribed half a dram of this Powder, to be taken conſtantly every three hours, in a ſpoonful of the following Julep, *viz.* Take of the Roots of Tormentil in Powder, drams two, of the beſt Bole Armonie, dram one, of the ſpecies of Hyacinth half a dram, make a Powder. Take of the Compound Water of Scordium, of Dragons, of Meadow-ſweet,

dow-ſweet, each three ounces, of Therecal Vinegar one ounce, of the Syrup of Corals two ounces, of Harts-horn burnt half a dram; make a Julep. Beſides, I ordered to be boiled in her Broths, and in every thing ſhe drank, the Roots of Tormentil; by theſe Remedies, the purging of her Womb was ſoon wholly ſtopp'd, and the Small Pox by degrees being ripened, came off without any grievous ſymptom.

Indeed this caſe was difficult, and was cured with great danger, *viz.* for either the Lochia, or the Small Pox to have been reſtrained inwardly, was very dangerous, and yet the more full eruption of the one, hindred the motion of the other; ſo long as either moderately proceeded, things being permitted to the conduct of Nature, was moderately well; but when one of them became ill, the work of Art was required, and it was requiſite to bridle the Lochia, but to provoke the Small Pox.

Chap. XVII.

Of Epidemical Feavers.

HAving meditated rather a Commentary, than an entire Tract, I had thought here to have concluded our Diſcourſe of Feavers: But foraſmuch as certain Epidemical Feavers do often ſpread, which obſerve no Laws, nor can be brought to no certain Rule of Doctrine, but being irregular, vary every year, and for that reaſon, as often as any of them increaſe or ſpread abroad, preſently it is call'd the New Diſeaſe; therefore I thought it worth our while, becauſe general Precepts concerning theſe Feavers, are not to be delivered, to ſubjoyn ſome particular Hiſtories, of ſome of this kind; for out of the various proviſion of Symptoms, whereby they are wont to be noted, the nature and the whole formal reaſon of theſe kind of Diſtempers, may ſomewhat appear. Since therefore of late years, within a ſhort Tract of time, three popular Diſeaſes have ſpred in theſe Countries, I will add, as a Crown to this Work, the ſeveral Deſcriptions of them, made at thoſe times, when theſe Feavers raged.

A Deſcription of an Epidemical Feaver, ſpreading about Autumn, in the Year 1657. *taken in the middle of* September.

WHilſt we meditate the Deſcription of a Feaver, at this time cruelly raging, it is fit, that following the example of *Hippocrates*, we firſt conſider the foregoing conſtitution of the Year, its intemperance and exceſs of qualities. For Epidemical Diſeaſes, and commonly excited among the people, are from a common Cauſe; ſuch as the habit of the Year, and by that means contracted, a diſpoſition of the Blood, by which many are alike affected. But that we may draw the Matter from the beginning, the laſt Spring, and the time ſucceeding it, even to the end of the Summer, was all that half years ſpace extreamly dry and hot, but eſpecially after the Summer Solſtice, the heats were ſo intenſe for many weeks together, that day and night there was none that did not complain of the heat of the Air, and were almoſt in a continual ſweat, and were not able to breath freely: About the Calends of *July*, this Feaver, at firſt ſporadical or particular, began to break forth in ſome places, that perhaps one or two were taken in the ſame City or Village: In many it imitated the likeneſs of an intermitting tertian Feaver, *viz.* the Fits returned every other day; which yet infeſted the ſick with a moſt intenſe heat, without any cold or ſhivering going before; Vomiting and Choleric Stools plentifully hapned to moſt, ſweat ſucceeding, but difficultly, and often interrupted, whereby the feaveriſh fit rarely ended in a remiſſion, but that all the time between, the ſick continued languiſhing and weak, with thirſt and reſtleſsneſs; in ſome, when the buſineſs began to grow better, after three or four fits, cold and ſhivering began the fits, and the Feaver became an exact intermitting Tertian; but in moſt, the Feaver ſtill grew worſe, and preſently became of an evil nature, and difficult cure, with a depraved proviſion of ſymptoms; for when the ſick were highly heated in their fits, and hardly ſweated, they were wont to commit errors, which daily increaſed the ſtrength of the Diſeaſe, becauſe by reaſon of the impatience of the ſick, and the unskilfulneſs of Servants, the ſweat being interrupted, which ſhould have ended the fit of the Feaver, after one fit was ſcarce finiſhed, another preſently ſucceeded, and ſo the Diſeaſe was wont to have wandring and uncertain periods, without any intermiſſion between, and afterwards to paſs into a kind of continual Feaver. The condition of which, ſome-

times being very dangerous, with an evil affection of the Brain and nervous ſtock, ſo that oftentimes a Lethargy, or Dilirium, or not ſeldom cramps and Convulſive motions, were excited: About the month *Auguſt*, this Feaver began to ſpread far and near, among the people, that in every Region and Village many were ſick of it; but it was much more frequent in the Country, and ſmaller Villages, than in Cities or Towns. It was ſtill like an intermitting Feaver, unleſs that it ſeemed more infeſtous than that is wont, and with more cruel fits, and ſhorter intermiſſions, and therefore was called the new Diſeaſe: beſides, it underwent the note of a certain malignity, and gave knowledg of its Contagion and Deadlineſs; inſomuch, that it crept from houſe to houſe, infected with the ſame evil, moſt of the ſame Family, and eſpecially thoſe familiarily converſing with the ſick; yea, old Men, and Men of ripe Age, it ordinarily took away.

If you reſpect the nature and eſſence of the Diſeaſe, this Feaver properly ſhould be referred to the rank of intermitting Feavers, for the Fits returned at ſet times, alſo for the moſt part they began with cold and ſhivering, and ofteneſt with vomiting, and by and by a moſt intenſe heat proceeding they were finiſhed, at laſt with a ſweat. The Urine in moſt appeared of a flame colour, thin in the fits, with ſome hypoſtaſis, without it more thick, and with a rediſh ſediment; altho with a moſt copious ſweat, and often iterated, the Diſeaſe was not cured, which might then be expected in a coutinual Feaver; yea, the diſtemper continued exceeding long, for many days, ſometimes months, tho much evacuation almoſt daily happned by vomit and ſweat; which we obſerve frequently in an intermitting Feaver, rarely to happen in a continual: out of the fit, at any time of the Diſeaſe a purge was profitably inſtituted, which in a Synochus before the ſign of concoction, were a wicked thing to attempt; beſides that this Feaver was of the intermitting kind, it ſeems to appear from hence, becauſe that very many recovered of, that ſcarce one of a thouſand died, which I ſcarce ever knew in an Epidemical Synochus. About the firſt bginnings of this Diſeaſe, it appeared very like to an intermitting Tertian, altho afterwards in ſome, by reaſon of the vitious proviſion of their body, and errors committed in Dyet, and ſweating it ſeemed to change into a continual; for in whom the fits were not rightly concluded nor ended in a remiſſion, by reaſon of the morbific matter not being throughly diſperſed, their Blood was continually hot, from whence in came to paſs, that the fits ſooner returned, and continued longer; till at length, by reaſon of the plenty of matter and the languiſhment of Nature, the Blood being made weaker endeavoured no longer to ſwell up and to ſeperate the feaveriſh matter, at ſet hours, but to ſubdue it by little and little, with a cantinual effervency.

We are to inquire concerning the cauſes of this Diſeaſe, what may be the leading, evident and conjunct cauſe, by the means of which is ſpread ſo generally, and became Epidemical through all *England*; by what means, and for what occaſion, it was wont to be excited in all men: and laſtly; what kind of alteration of the Blood and humors, being induced brought forth this kind of Feaver, with ſuch a proviſion of ſymptoms, and conſerved it in the Act.

I know it is eaſie to place wholly the cauſe of this ſo popular Diſeaſe in the malignant conſtitution of the Air, to wit, that the particles of the Aire which we breath, were infected by a certain extraneous infection and not agreeable to our Nature, the little bodies of which Infections being admitted within, did ferment with the Blood and humors, and ſo in moſt, brought in this Feaver, almoſt with the ſame appearance of ſymptoms. For who dares deduce the Original of a Diſeaſe ſo generally raging from a leſs publick fountain? Or refer to any other place, the received cauſes of Diſeaſes, than to that neſt of Vital Air, on which every one feeds? But whilſt I more attentively conſider the thing, it ſeems to me, that its ſtem, and as it were its firſt beginnings, are to be ſought a little deeper. To wit, that this Feaver is born not from the Contagion communicated by the Air, and immediately fixing its evil on men, but rather from a certain feaveriſh prediſpoſition or nature, impreſſed ſomewhile before on our Bodies, becauſe of the intemperance of the Year, which at length having gotten maturity, on the leaſt occaſion is brought into Act, and ſo breaks not forth into this Feaver, ſo much as it ſifts it forth.

For when upon the Calends of *July*, the Air was immoderately hot, with a moſt intenſe heat for many days, it eaſily altered our Blood towards an hot and bilous intemperance, by which (as in wine growing more hot than it ſhould do) the ſweet part and the ſpirituous was much conſumed, in the mean time, the Saline and the Sulphureous was too much carried forth, that by that means, the liquor eaſily contracted a rancor or ſourneſs: We have in another place ſhewn, that this kind of diſpoſition of the Blood, whereby indeed it turns from a ſweet and ſpirituous temper, into a boylous or choleric, is moſt apt for an iutermitting Feavers: Hence the alible juice, which is continually carried into the maſs of Blood, is not rightly concocted, nor aſſimilated into Blood, but perverted as it were into extraneous and fermentative matter; which ariſing to a fulneſs in the boſom of the Blood it ſelf, and growing turgid according to its increaſe at ſet periods, as we have already ſhewn, induces

the

the fits of the intermitting Feaver: when therefore, from the great burning heat of *this* Summer, the Blood almoſt of all men, becoming more hot than uſual, was very much ſcorched, it is no wonder, if from thence it ſhould contract a great aptitude for intermitting Feavers. But why not whileſt the fervor of the Heaven was yet urgent, but a little after, this Diſeaſe ſpread it ſelf, the reaſon is, becauſe this indiſpoſition is not impreſſed on our Blood at once or at one time, but by little and little, and not but of along time; and therefore Diſeaſes like Fruits, are chiefly ripened in Autumn, after the foregoing heat of the Summer.

This aptitude or feaveriſh diſpoſition, all do not contract alike; thoſe whoſe Blood is of a more hot Nature, and abounds more in Sulphur, and for that cauſe is ſooner ſcorched, alſo ſuch who labour, or ſtay long in the heat of the Sun, and open Air, by reaſon of their Blood being more remarkably torrified, more eaſily fell into this Diſeaſe; wherefore, at firſt, it chiefly raged among Husbandmen in the Country: of theſe, who had required an aptitude to this Feaver, from the Blood being before ſcorched, ſome perhaps fell into this of their own accord, the feaveriſh diſpoſition being leiſurely carried forth to a maturity; others by reaſon of a light occaſion or evident cauſe, which was wont otherways to ſtir up the feaveriſh burning, as from taking Cold, Surfeit, drinking of Wine, and the like; and others fell ſick from the Contagion received of others, for as the *effluvia* conſtantly came away from the ſick, when they peirced Bodies prediſpoſed to the like diſtemper they eaſily excited the hid powers into Act.

As to the third Propoſition, to wit, that the conjunct cauſe of this Diſeaſe, and its formal Reaſon, may be known, we muſt put you in mind of thoſe things, which we have elſewhere delivered concerning the nature of intermitting Feavers, for we ſuppoſe the torrid and bilous conſtitution of the Blood, as the baſis of this Diſeaſe, by reaſon of which the alible juice being ſupplied daily, as it were in a certain meaſure, is not rightly concocted, but by the aſſation or ſcorching, becomes or goes into a fermentative matter, not miſcible with the Blood. When the Blood is filled to a fulneſs with this matter (which happens at ſet intervals of times, becauſe the alible juice is ſupplied as it were by a ſet meaſure) it of its own accord conceives a ſwelling up, and the growing hot or effervеſcency being excited, for the carrying away of this matter, cauſes the feaveriſh fit: which ſo long indures till this feaveriſh matter being inkindled, and as it were burnt in the heart, is wholly diſſipated with ſweat.

From theſe things premiſed, it is made plain, that in this diſtemper, we now diſcourſe of, there are ſome things happen by a peculiar way, from the common kind of intermitting Feavers, and therefore it was noted, that not undiſervedly, with the appellation of a new Feaver; which are, Firſt, that about the beginning of the Diſeaſe, fits did a long while afflict the ſick, without cold or ſhaking, but with a moſt intenſe heat, thirſt, and cruel vomiting; by which, the ſweat hardly, and for the moſt part partial, and often interrupted, ſucceeded, whereby the fit was not finiſhed but of a long time. The reaſon of which, may be only laid upon the very choleric diſpoſition of the Blood, and being above meaſure ſcorched: For this proceeding from the domineering Sulphur, wholly inhibits the wonted ſourneſs of the Blood, which follows its turgency or ſwelling up, and is wont to ſtir up the cold or ſhivering; and by reaſon of this kind of temper of Blood, too much roaſting and as it were burning the alible juice, the Blood growing turgid, together with that juice, and being ſtirred up into motion, is inkindled more then it was wont in the heart, and by its deflagration, induces a moſt intenſe and troubleſom heat, with thirſt, to the ſick. Choleric vomitings, happen not only at the beginning but in the middle of the fit, by reaſon of the abundance of choler, with which, the Choleduct Veſſels being too much filled infuſe the inteſtines; which then a Convulſion being ſtirred up, is eaſily emptied into the Ventricle: Sweat hardly ſucceeds, becauſe the bile abounds more than the ſerum, wherefore the Feavouriſh matter being burnt, it is not eaſily ſifted forth by ſweat, but being either mingled with the Blood, cauſes the long effervency, or being carried towards the inteſtines, produces vomiting or a Flux. Secondly, This Feavour differs from the vulgar intermiting Feavour, becauſe after the fit was ended, there was no full intermiſſion, even to a remiſſion, but the ſick ſtill remained languiſhing and thirſty; and as to appetite, ſleep, and other accidents, very ill: which indeed happened, becauſe, by the intenſe heat of the fit, more of the Blood and feaveriſh matter is inkindled, than that its recrements remaining after its deflagration, are able preſently to be diſſipated, eſpecially, becauſe the ſweat, by reaſon of the dryneſs of the matter, very hardly ſucceeds, nor is the Feaveriſh matter enough diluted with the ſerous *Latex*, to be ſifted forth; wherefore, the Blood by its Contagion in the time of the fit, not being perfectly freed, grows hot ſtill, neither the fit being ended, doth it get any full truce from the diſeaſe: In the mean time, whilſt the Blood is urged after this manner, with almoſt a continual effervency, it differs from a Synochus; becauſe in this, the Sulphureous part of the blood, being too much carried forth, and as it were inflamed, cauſes the Feaver by its deflagration; but the continual ebullition, which

which after this manner comes upon this intermitting Feaver, wholly depends upon the confusion of the not miſcible matter, and its hard ſecretion from the Blood. The Synochus happens like Wine growing hot of its own accord, by reaſon of its richneſs, the other conceives its fury, like the ſame Wine, by reaſon of ſome heterogeneous thing powred to it: wherefore we remark, that whilſt our Feaver is ſeen ſtill to be continual, it is not cured by Sweat or the Flux of the Belly, altho they frequently and copiouſly happen; becauſe it depending upon the Blood being depauperated, rather than being inflamed, it continues long, and diſpoſes the ſick towards a Cachexie.

3. There is a third reaſon of difference, by which this Feaver may be diſtinguiſhed from the common rank of intermitting Feavers, and it is this, that it is eaſily propagated to others by contagion; the reaſon of which is, becauſe here very many Bodies are prediſpoſed after the ſame manner, towards the ſame Diſtemper, which happens not at another time; wherefore, the meer Effluvia's from a diſeaſed Body, are able to excite the like effect, in a very fit ſubject; even as ſome beams of Flame enkindle Flame, in a very combuſtible matter: In the mean time all do not alike contract the Infection of this Feaver, but that ſome being leſs prepared or fitted for it, converſe with the ſick without harm.

4. There is another Symptom occurs, not conſtant to this Feaver, but only hapning in ſome places, that diſcriminates it not only from the common, but varies its own proper type; to wit, ſometimes it happens, this Diſeaſe to be accompanied with a Dyſenterick Diſtemper; in ſome Cholerick Vomits, and Bilous Stools very much infeſt; and in others Bloody Stools follow, with cruel pains and torments of the Belly. The former I often obſerved in our Neighbourhood, and the reaſon of it may be deduced from the higheſt bilous temper of the Blood: For by reaſon of this, the aduſt matter, not to be diſſipated by Sweat, is copiouſly ſifted into the Liver; then by reaſon of the Choler-carrying Veſſels, being filled to a flowing over, it is ſent away to the Ventricle and Inteſtines. The other Dyſenterical Diſtemper was found only in ſome places, and there peculiar rather than common, it laid hold only of ſome ſick. The Origine of it may be referred to the peculiar diſpoſitions of ſome Bodies, or vicious proviſion, alſo to the ſite of the place, or condition of the Air; then the Diſeaſe is to be ſuſpected, to be thence tranſlated to others, not without the communication of a certain infection.

There is to be had a double Prognoſtication concerning this Diſeaſe: Firſt, of the Feaver in General, what end it ſhall have, when, what it may threaten to the Land: whether it precede not (which is commonly feared) the Plague, or Peſtilential Sickneſſes. Secondly, The ſigns ought to be laid down, whereby we are wont to preſage health, or danger, in the various caſes of the ſick.

As to the firſt, Becauſe we have ſhown that the Origine of this diſtemper is not to be fetched from the Contagion of the Air, or its being infected with any venomous Infection, nor from any malignant ſeeds of Vapours diffuſed through the Air, but only from the ſignal bilous temper or diſpoſition of our Bodies, with the Blood being made aduſt and roaſted extreamly, by reaſon of the Summer heats, I think there is no reaſon of fear, that this Feaver ſhould be carried forth into any thing worſe by the vice of the Air, or might at length grow to be Malignant or Peſtilential. But rather (that the ſeaſon of the Year being changed, and the alteration of our Blood aſſuredly to be expected) we might fear leſt this Feaver, which now imitates the way of an intermitting Feaver, ſhould afterwards paſs into a Quartan, the Blood growing into a melancholy temper. Which thing indeed I obſerved to happen to ſome already, and I believe, that before the Autumn be fully paſſed over, will happen to many more.

As to the particular Prognoſtication, the chiefly notable ſigns, which occur in the courſe of this Feaver, and in a manner foretel its condition and event, are of this ſort; if the Diſeaſe happens in a firm Body, well tempered, and eaſily perſpirable; if vomiting with eaſe ſucceeds, and that the Belly be looſe: if the fit begins with a light ſhivering, and afterwards a moderate heat, with ſweat concludes it, and that the intermiſſion be with ſome tolerable remiſſion; if the Pulſe be ſtrong, the Urine of a flame colour, clear, and with a laudable hypoſtaſis, we may Predict that the Diſeaſe will quickly end without any danger. But if this Feaver be excited in a fat Body, and of a vicious habit, if with troubleſome vomiting, an intolerable thirſt, and fierce heat, long exerciſe the ſick; if to the heat a difficult ſweat, and partial, and often interrupted, and between frequent vomitings ſucceed, and that it ends not in a remiſſion, we may declare, that this Diſeaſe may be long, and of a dangerous iſſue. But if the ſick remain in ſtrength, and the Urine ſhew ſigns of concoction, we need not diſpair of health; eſpecially, if after four or five periods, the Diſeaſe, as it is wont to do, remits of its wonted fierceneſs. Thirdly we obſerve, if this Diſeaſe is excited in an old Body, or others broken with ſickneſſes, or debilitated; if beſides horrid vomitings, there happen ſwoonings, faintings, Deliriums or Lethargic diſtempers; if after many fits, the ſick having loſt their ſtrength, the Diſeaſe remits nothing, but exerciſeth the Blood, with a continual effervency, and that the Vital Spirits are much deſtroyed; if the appetite be loſt, wakings pertinacious, and that they

have

have Convulſive motions, with a weak Pulſe, and Urine troubled, or thick, we judge the matter to be full of danger: yet is not the ſick to be left as deſperate, becauſe the Diſeaſe is not haſty, and kills not ſuddenly, and out of hand; but is drawn out at length, and grants time and occaſions to nature, of recollecting her ſelf, and to the Phyſician, of giving Remedies.

The Therapeutic Indications, which have place in the Cure of this Feaver, are chiefly four. Firſt, That the Blood being now ſcorched, and made too cholerick, may be reduced to its due temper. Secondly, That the depravation of the nouriſhable juice, and its alteration into a fermentative matter, may be inhibited, or at leaſt leſſened. Thirdly, That about the declining of the Diſeaſe, the Blood depauperated by a frequent deflagration, and made more impure by the fuſion or pouring into it the morbific or aduſt matter, may be reſtored, and rendred as it ſhould be volatile. Fourthly, That the ſymptoms, which chiefly infeſt in the courſe of the Diſeaſe, may be timely helped by fit Remedies; that theſe intentions may be ſatisfied, I counſel that this following method be uſed.

About the beginning of the Diſeaſe, if the bilous or choleric humor, flowing forth of the choler-bearing Veſſels, and being ſuffuſed into the Ventricle, cauſe the ſick to be prone to vomiting, let a more plentiful evacuation be procured, by a gentle Emetic in the time of the fit: The opening of a Vein, and Purging, ought not to be adminiſtred, unleſs between the fits: for whilſt the Blood grows mainly hot, or is reſolved into ſweat, Nature ought not to be called back from the Work begun, nor her endeavours to be diſturbed, by the preſcriptions of Phyſicians; wherefore, after the fit being paſt, and the ſweat throughly finiſhed, a Purging may be inſtituted, by a gentle Cathartic, and the ſame afterwards ſometimes repeated, on the like occaſion: for by this method, not only the proviſion of the excrementitious matter, is brought away, from the firſt paſſages, but chiefly the choler-bearing Veſſels being emptied, the choler is copiouſly drawn forth from the maſs of Blood, and by that means the Blood is reſtored to its natural Craſis or diſpoſition. The letting of Blood, if it be indicated, ſhould be performed preſently after the beginning; for ſo its Liquor being too turgent or ſwelling up, is eventilated, whereby both the nutritious juice is leſs perverted, and the fit urging, it burns forth with a leſs heat, together with the morbifick matter: but otherwiſe, if a Vein be opened after a long ſickneſs, when the Blood being made poorer, and more watry, more of the morbifick matter is heaped together, and does not rightly concoct, and ſift it forth, it detracts much from the ſtrength of Nitre, and nothing from the power of the Diſeaſe. In the interval of the fits, when there is no place for opening a Vein, nor Purging, let the Belly be kept looſe, by the conſtant uſe of Clyſters; alſo digeſtive Remedies, of acetous or ſaline Liquors and Powders, are to be exhibited; of which ſort are Cream of Tartar, fixed Salts of Herbs, Tartar Vitriolate, Harts-horn burnt, Spirit of Vitriol, and Salt, *&c.* for theſe reſtore the loſt or ſleepy ferments of the Viſcera, purifie the Blood by fuſing it, alſo ſeparate the morbifick matter, and as it were precipitate it: alſo, at this time between, if pertinacious waking infeſt the ſick, and overthrow their ſtrength, it may be lawful to adminiſter anodyne, and gentle narcotic Remedies; but never in the fit: for then they greatly hinder the ſubduing, and ſifting forth of the feaveriſh matter, and draw out in length the fit that would end ſooner.

Theſe things are tō be done about the interſtitia, or intervals of the fits; but whilſt the fit is urgent, altho' the ſick then chiefly ſend for, and call upon Phyſicians, yet at this time their Preſcripts are limited to a narrower ſpace: If Vomiting (notwithſtanding an Emetic being given) ſtill infeſt, it may be more freely provoked, either by ſimple Poſſet Drink, or with bitter Herbs boiled in it: But let the chiefeſt means of help be, in temperating the heat and thirſt, which moſt grievouſly torments the ſick in this Feaver: For whilſt the Blood growing hot, with the morbifick matter, and being inkindled in the Heart, leaps forth into the Lungs, ſtirs up there a cruel Inflammation, which requires a profuſion of a cold humor, as it were for the extinguiſhing the Flame; wherefore they greedily deſire without any meaſure drink, for want of which the ſick are almoſt killed with too great heat, and their Blood being almoſt wholly rarified into flame and fume, the thrid of Circulation is hardly continued; wherefore, drink ought to be wholly granted, to thoſe in Feavers: which however, if it be taken in too large a quantity, it at firſt more diſturbs the eſtuating Blood, and at length brings confuſion to the feaveriſh matter, begun to be ſeparated; that from thence, the Work of ſubaction and ſecretion is longer protracted, and the fit is made longer: alſo, beſides, large drinking cauſes troubles in the Ventricle, and by diſturbing it, and often provoking Vomiting, hinders the breathing forth, and calls inward the ſweat breaking forth, or perhaps already broke forth: wherefore, at firſt, the heat of the Feaver being inkindled, altho' the ſick be very thirſty, let them only ſip a little, and abſtain from drink as much as they can; afterwards, when the matter being burnt, and ſubdued, begins to be diſſipated by ſweat, they may be more freely indulged as to this, for ſo the ſweating is greatly helped, and the fit is ſooner finiſhed: as to the nature of the Drink, let them take ſometimes Poſſet Drink, ſometimes Small

Beer,

Beer, or Barly-Water, and ſometimes ſimple Water, or ſharpned with the Juice of Limons: In this caſe, the uſe of Sal prunellæ is deſervedly praiſed, to be given in every Liquor; for this, with its nitroſity, wonderfully allays the raging Blood, and potently moves Sweats: I have often obſerved, in the midſt of a Fit, the ſick wont to fall into a Swoon, or Syncopy, to whom preſently they give Cordials or hot Waters, that much increaſe the violence of the Feaver, and bring forth more troubles than uſual, that the Fit is more difficultly finiſhed; but theſe faintings, for the moſt part, happen, either from a bilous humor ſuffuſed in the Ventricle, or by reaſon of the ſweat ſuddenly breaking forth; and againſt theſe, I always found the moſt preſent Remedy, that either a feather being put down the throat, Vomiting may be provok'd, or that Liquor being plentifully drunk, a ſweat may be again raiſed up; alſo in the whole courſe of this Feaver, I am wont never to give any Cordials, or Alexiteriums.

The Diet in this Feaver ought to be only ſlender, and not nouriſhing, all ſorts of Fleſh, or any prepared of them, are wholly to be avoided; for as theſe abound with Sulphur, they give a more plentiful food (as Oyl poured on Flame) to the hot or enkindled Blood: Beſides, nothing ſpirituous, as ſtrong Waters, ſtrong Beer, or Wine, is to be yielded to; but Decoctions, or Broths of Oatmeal, or Barly, altered with cooling Herbs, are chiefly to be uſed; alſo Poſſet-Drink, and Small Beer, or Whey, is to be given them at their pleaſure: for by this means, when a very ſlender and watry nouriſhing Juice is conveyed to the maſs of Blood, the ſoluted Particles of Sulphur, burn forth ſooner, and with the leſs tumult; alſo the Recrements of the aduſt matter are more eaſily carried from the boſom of the Blood; but if on the contrary, a more rich or plentiful Nouriſhment be adminiſtred, the effervescency of the Blood is thereby very much augmented, and the Blood is more infected, by the confuſion or pouring in of the aduſt matter.

After that the Blood being much burnt forth by frequent fits, and the Feaver being in its declination, remits of its fervor and fierceneſs, you muſt take heed, leſt the ſick at length growing well, fall not into a Cachexy, or Scorbutic Diſtemper; for the diſpoſition of the Viſcera being hurt, and the Blood being much depauperated, the alible Juice, though not ſcorched ſo as at firſt, is not however rightly concocted, and ripened into perfect Blood; but by reaſon of the want of Tranſpiration, the ſerous Excrements being imbued with a fixed Salt, are greatly heaped together, and now fixed in the Bowels, now in the extreme Parts, bring forth various Diſtempers. Wherefore in a long languiſhing of the ſick, or otherwiſe for the ſake of being ſooner well, Remedies ſhould be given them, which volatilize the Blood, or hinder the ſtuffings of the Viſcera, or if ſtuffed, may open them, and their ferments as if extinct, reſtore: for this uſe, thoſe Remedies and Preparations chiefly help, which are commonly called Digeſtives and Antiſcorbuticks; with which, being timely adminiſtred, I have known very many weak, pale, and as it were without Blood, ſuddenly to recover a Livelineſs and Vigor.

The Deſcription of a Catarrhal Feaver Epidemical in the middle of the Spring, in the Year 1658. *taken the fourth of* June.

AN equally intenſe Froſt followed the next Winter, the immoderate heat of the foregoing Summer, ſo that no one living could remember ſuch a Year, for either exceſs both of heat and cold. From the Ides of *December*, almoſt to the Vernal Equinox, the Earth was covered with Snow, and the North-Wind conſtantly blowing, all things without doors were frozen: Alſo, afterwards, from the beginning of the Spring, almoſt to the beginning of *June*, the ſame Wind ſtill blowing, the Seaſon was more like Winter than Spring, unleſs now and then a hot day came between. During the Winter (unleſs that a Quartan Feaver contracted in Autumn, infeſted ſome) among our Countrimen, there was a moderate ſtate of Health, and freedom from all popular Diſeaſes. The Spring coming on, an intermitting Tertian (as uſed to do every year before) fell upon ſome. About the end of *April*, ſuddenly a Diſtemper aroſe, as if ſent by ſome Blaſt of the Stars, which laid hold on very many together; that in ſome Towns, in the ſpace of a Week, above a thouſand People fell ſick together. The particular ſymptom of this Diſeaſe, and which firſt invaded the ſick, was a troubleſom Cough, with great ſpitting, alſo a Catarrh falling down on the Palat, Throat and Noſtrils; alſo it was accompanied with a feaveriſh Diſtemper, joyned with heat and thirſt, want of appetite, a ſpontaneous wearineſs, and a grievous pain in the Back and Limbs; which Feaver however was more remiſs in ſome, that they could go abroad, and follow their Affairs in the time of their ſickneſs, but complainining in the mean time, of want of ſtrength, and of languiſhing, a loathing of Food, a Cough, and a Catarrh: But in ſome a very hot Diſtemper plainly appeared, that being thrown into Bed, they were troubled with burning, thirſt, waking, hoarſeneſs, and coughing, almoſt continual; ſometimes there came upon this a Bleeding at Noſe, and in ſome a bloody Spittle, and frequently a bloody Flux; ſuch as were

were indued with an infirm Body, or men of a more declining Age, that were taken with this Diſeaſe, not a few died of it; but the more ſtrong, and almoſt all of an healthful conſtitution recovered; thoſe who falling ſick of this Diſeaſe, and died, for the moſt part died by reaſon of the ſtrength being leiſurely waſted, and a ſerous heap more and more gathered together in the Breaſt, with the Feaver being increaſed, and a difficulty of Breath, like thoſe ſick of an Hectic Feaver. Concerning this Diſeaſe, we are to enquire, what procatartic cauſe it had, that it ſhould ariſe in the middle of the Spring ſuddenly, and that the third part of Mankind almoſt ſhould be diſtempered with the ſame in the ſpace of a Month; then the ſigns and ſymptoms being carefully collated, the formal reaſon of this Diſeaſe, alſo its Criſis and Way of Cure ought to be aſſigned.

That the Northern Wind is moſt apt to produce Catarrhs, beſides the Teſtimony of *Hippocrates*, common Experience doth make known: But why Catarrhs did not ſpread, at leaſt in ſome peculiar places, all the Winter and Spring, but only in one Months ſpace, and then joyned with a Feaver, this Diſtemper ſhould become Epidemical, doth not ſo plainly appear. I know many deduce the Cauſe from the unequal Temper of the Air at that time; which although for the moſt part very cold, yet the North-Wind ſometimes leſſening, there would be a day or two very hot between: wherefore from this occaſion, as from cold taken after the heat, men ſhould commonly fall ſick: But indeed, for the exciting the Diſtemper, ſo ſuddenly riſing, and commonly ſpreading, there is required, beſides ſuch an occaſion, a great foregoing Cauſe or Prediſpoſition, though the other might ſuffice perhaps, for an evident cauſe, for to diſtemper them with this Sickneſs; for we ought to ſuppoſe, that almoſt all men were prone to the receiving this Diſeaſe, otherwiſe no evident cauſe could have exerciſed its power ſo potently on ſo many; wherefore, it ſeems very likely, that this Diſeaſe had its Origine from the intemperance and great inordination of the Year: and as the Autumnal intermitting Feaver before deſcribed, was the product of the preceding immoderate heat, ſo this Catarrhal Feaver depended altogether upon the following part of the Year, being ſo extreamly cold; for the Blood being now throughly roaſted, by the very hot Summer, and prone to the Feaver before deſcribed, then being made more ſowriſh by the Autumn urging it, and apt for a Quartan Feaver, afterwards being a little eventilated by reaſon of the ſtrong Cold of the Winter, and hindred from its due perſpiration, retained yet its Dyſcraſie, or evil Diſpoſition, and readily broke forth on the firſt occaſion given: wherefore, when the Blood, in the middle of the Spring (as the Juice of Vegetables) being made more lively, and alſo begun to flower, and grow rank, by reaſon of the ſtoppage being ſtill continued, was ſtraitned in its Circulation, and eaſily made prone to a feaveriſh effervеſcency: and as the ſerous Water redounding in the Blood, could not evaporate outwardly, becauſe of the Pores being ſtill ſtraitned by the cold, reſtagnating within, and chiefly falling upon the Lungs (where it might be moved about, inſtead of an outward breathing forth) excited the ſo frequent and troubleſome Cough.

The Original therefore, and formal Reaſon of this Diſeaſe, are founded chiefly on two things, to wit, that there together hapned a greater effervеſcency of the Blood than uſual, from the coming on of the Spring-Seaſon, and alſo a Stoppage, or great conſtriction of the Pores, excited by the too great Cold of the foregoing Seaſon; that therefore there was not a free ſpace granted to the Blood, flowring or luxuriating in the Veſſels: the buſineſs being after the ſame manner, as if Wine begun to grow hot, ſhould be put up into cloſe ſhut Veſſels; for by this means, either the Veſſels, or the Liquor were in danger to be loſt.

Wherefore, that we may contract the thing in ſhort, the cauſe that this Diſeaſe begun in the middle of the Spring, having preſently ſpred largely, ſeized very many, was not the blaſt of a malignant Air, whereby the ſick were diſtempered, as if ſtruck with a blaſting, but that at this time, the Blood being inſpired by the conſtitution of the Spring, and ſo luxuriating, and apt to grow hot, was contracted or ſtraitned in its motion, and the effluvia's being conſtrained inwardly, could not be ſufficiently eventilated or cooled. In every year, tho temperate, it is uſual in the Spring and Autumn for ſome Epidemical Diſeaſes to reign, becauſe at this time, the Blood being as it were reſtored, flowers anew; and therefore, intermitting Feavers, and ſometimes the Small Pox ordinarily ſpread in this Seaſon; wherefore, 'tis no wonder, after a great unequal conſtitution of the Year, and not natural, when in this Spring, the Blood boyling up more lively within the Veſſels, by reaſon of tranſpiration being hindred, could not be freely circulated, and ſufficiently eventilated, if for that cauſe, great diſorders follow, and from this moſt common cauſe, a Diſtemper greatly Epidemical ſhould be excited.

As to the Symptoms joyned with this Diſeaſe, a feaveriſh intemperature, and whatſoever belongs to this, the heat of the *Præcordia*, thirſt, a ſpontaneous wearineſs, pain in the Head, Loyns, and Limbs, were induced from the Blood growing hot, and not ſufficiently eventilated; hence in many, a part of the thinner Blood being heated, and the reſt of the Liquor being only driven into confuſion, a ſimple Synochus, or of more days was induced, and this

for the moſt part ceaſed within a few days: But in ſome endued with a vicious diſpoſition of Blood, or evil habit of Body, this kind of Feaver ariſing by reaſon of the ſame cauſe, quickly paſſed into a very dangerous Putrid Feaver, and often Mortal.

The Cough accompanying this feaver with a Catarrh, draws its Origine from a ſerous humour heaped up together in the Blood, by reaſon of tranſpiration being hindred for a long time, and then an effervescency being riſen, dropping forth more from the little Arteries, gaping within; for when the Pores are conſtrained, the ſuperfluous ſeroſities in the Blood, being wont to evaporate outwardly, are poured forth on the Lungs, by a proper caſtration or cleanſing of the blood, wherefore, by taking cold (as they commonly term it) that is, from tranſpiration outwardly being hindred, the Cough for the moſt part is ſtirred up: And for a foregoing cauſe to this Diſtemper, the flowing forth of the ſerum into the Maſs of Blood, hath for the moſt part the chief place; for, from the long cold hindring the ſcorching of the blood, or the proviſion of the Bile, and prohibiting the breathing forth of the watry humor, there was a neceſſity, that very much of the ſerous Humor ſhould be heaped up in the Blood: wherefore, when the Blood flowring in the Spring, conceived a heat, the flowing forth of the Serum, and a powring of it on the interior parts, was wont to cauſe firſt the Cough, as the proper ſymptom of this Diſeaſe; and thoſe, whoſe Blood was more diluted by the mixtion of the Serum, and who were greatly obnoxious to the Cough, and a Rheumatic Diſtemper, were cured with leſs trouble of the feaveriſh Diſtemper. The Prognoſtick of this Diſeaſe, concerning private perſons, is for the moſt part eaſie, that one may deliver the event, from the firſt aſſault; for if this ſickneſs be excited in a ſtrong body, and healthful before, and that the feaveriſh Diſtemper be moderate, and without any grievous and horrid ſymptom, the buſineſs is free from danger, and the Diſtemper is to be accounted but of light moment, as that commonly is of catching Cold, neither needs a Phyſician be conſulted, nor Remedies, unleſs trivial and ordinary, be adminiſtred: But if this Diſtemper happens in a weak and ſickly Body, with an evil proviſion, or that the Feaver being carried into putrid Feaver, or the Cough growing grievous, induces difficult breathing, and as it were a tabid or conſumptive diſpoſition, the event of the Diſeaſe is much to be ſuſpected, and often terminates in Death. The common Prognoſtic that was taken from hence, concerning the future ſtate of the Year, contains nothing to be feared, or ominates any great ill; by reaſon of the unequal intemperance of the Year, the great heats, and then exceſſive cold, we might fear Diſeaſes to ariſe from the Dyſcraſie of the Blood, yet from the preſent condition, we need neither ſuſpect any noted depravation of the Air, or Infection with poyſonous breaths; that from thence may be had any Judgment of the Plague, or Malignant Diſeaſe to be at hand.

As to what belongs to the Cure, when this Diſeaſe is more lightly inflicted, its Cure for the moſt part is left to Nature; for this Feaver, when it is only a ſimple Synochus, is wont to be cured within a few days by ſweat: wherefore, by a copious ſweating, for the moſt part about the third or fourth day, the heat and thirſt, the wearineſs, and heavy pains are allay'd; then the Cough being ſomewhat longer protracted, by little and little afterwards remits, and at length the ſick leiſurely grow well; if this Diſeaſe hath rooted it ſelf more deeply, there is need of fit Remedies, and an exact method of curing; the Feaver growing worſe is to be healed, according to the Rules to be obſerved in a Putrid Feaver; but nevertheleſs with this difference, that, becauſe tranſpiration being hindered, and the ſuffuſion of the ſerous humour on the Lungs, are chiefly in fault, therefore Diaphretic Remedies, and thoſe called Pectoral, are of more frequent uſe; for theſe reſtrain the flowing forth of the Serum from the Veſſels within, or by opening the Pores, convey it forth of doors; or precipitating it from the boſom of the Blood, ſend it forth by the Urinary Paſſages; therefore the Method of Medecine for this Diſeaſe, being brought into the worſer ſtate, reſpects both the feaveriſh intemperance, for the ſake of curing which, you are to be directed, according to the intentions ſhewn in the Putrid Feaver, and alſo the Rheumatic Diſtemper, which however let it be ſecondary, and not every expectorating Remedy, or thoſe uſed againſt a Cough, are to be admitted, but of that kind only which do not increaſe the Feaver: the forms of theſe, and the means of curing, are to be ſought from the Precepts delivered generally for the Cure of the Putrid Feaver, and of the Cough; the Helps, which now by frequent experience, are commonly ſaid to bring Cure chiefly in this Diſeaſe, are ſweating, or the provoking of Sweat, and letting of Blood; for the Veſſels being emptied by this or that means, both the immoderate heat of the Blood, and the abundance of the Serum are reſtrained.

A Deſcription of an Epidemical Feaver ariſing about the beginning of Autumn, 1658. *taken the* 13*th. of* September.

THE Vernal Feaver but now deſcribed, did not laſt longer than ſix weeks, that it plainly was ſeen, that it was only a more light flowring of the Blood, which ſwelling up in the Spring, and at the ſame time ſtreightned in ſpace, for want of ventilation, moſt impetuouſly boyled

boyled up, like new Wine close shut up in bottles, and then ceased of it self. Yet from thence, as neither the year, so neither our blood did recover its due temperature, and so another Tinder or Nest for a new Feaver, was quickly gathered together: because after the Summer Solstice, the North wind still blowing, a cold season remained for a long while; so that the Fruit and Corn this year, was feared by the Husbandmen, would scarce be throughly ripened; but after this, a little before the beginning of *July*, a most fierce heat followed, for several days; and when the Dog-days were begun, the Air grew most cruelly hot, that one could scarce endure the open Air. By reason of this Heat and Cold in excess, the temperature of this Year was very unequal: wherefore, there was a necessity for our Blood to be now fixed, and as it were congealed, now too much roasted, and so perverted from its natural disposition, to a scorched and Melancholy Temper; also it came to pass that the Pores of the skin were much altered from their right constitution, that by that means, an insensible transpiration could not be performed after the wonted manner.

From the time that the former Feaver ceased, almost to the end of the Dog-days, there was a state of Health, and free from all Popular Diseases; but then a few here and there among the Villages, and in lesser places, first fell sick; but afterwards, about the end of *August*, a new Feaver suddenly arising, began to spread through whole Regions, every where round about us; also this, as the other which spread the last Autumn, raged chiefly in Country Houses and Villages; but in the mean time, few of the Inhabitants of the greater Towns and Cities fell sick. At the same time, in other Regions, situate at a distance from us, almost throughout *England*, the Epidemical Feaver was said to rage; and in some other places, to be far more deadly than it was about our Country. Perhaps the Idea of this Feaver now reigning had not the provision of its Symptoms alike in all places, or was noted wholly with the same Appearances and Accidents: yet whatever it shewed in our parts, as to its Nature, I shall briefly and succinctly add, from our own proper observation, or what I had learnt, being communicated from others.

About the beginning of this Disease, its figure was wandring, and very uncertain; because in some there was a continual fervor, in others it was intermitting, being renewed by set fits; but at this time it happened to very many, as a pathognomic Symptom, that they were ill in their Brain and Nervous Stock, that presently from the very beginning of this Feaver, almost all complained of their Head being grievously distempered; For a cruel Head-ach infested some, and hardness of hearing, with a noise in the Ears troubled others, but to most was wont to happen, either a stupidness, and heavy sleepiness, with a vertiginous Distemper, or pertinacious wakings, with a Delirium, and distractions of the Animal Spirits. I have observed in some, that on the first or second day of their Sickness, that little broad and red spots, like to the Measles, have leisurely broke forth in the whole Body, which being shortly vanished, the Feaver presently became stronger, and especially the Distempers of the Head, far more grievous. From thence a benummedness of the Senses, and a Sleepiness fell upon some for many days, that they lay a long while as if dying, without speaking, or knowledge of their Friends. I knew others to have fallen from hence into a Lethargy, and others cast into an Apoplexy, and some into a Phrensie and Delirium. Of these the younger and strong men (yet not without a long languishment, and doubtful recovery) most of them escaped; in the mean time, old men, or other ways weak and sickly, generally died. Those who fell sick with the Feaver, as it were continual, with those notes of malignity, were more rare, and the distempered were only sporadically, in some Houses only, But the Sickness which most commonly spred about us, fell upon most, and tho it cruelly raged, it seemed to imitate an intermitting Feaver, to wit either a Tertian, or a Quotidian; for that the sick had fits, either every day, or (which I more often observed) every other day, which infested them grievously, and a long while, with Cold, Heat and Sweat, succeeding in order: but these kind of fits, as also the course of the whole Disease, were wont to be noted with diversity, according to the Age and Temper of the Sick, and with various concourse of Symptoms and Accidents. Yet this was common to most of (I had like to have said all) the sick, that together with the Feaver, they were troubled with Cephalic Distempers.

When therefore any one was troubled with this Disease (whether the Sickness was excited from an evident Cause or Contagion, or without any manifest occasion) its coming betrayed it self by a Pain in the Head, and often in the Loyns, with Thirst, Want of Appetite, spontaneous Weariness, and Heat tho not strong: If it hapned in a young Body of a florid Blood, and more hot temper, the Fits wanted the Cold and Shivering, about its beginning, but they were very troublesome and sharp, with long heat: The sick were often troubled with Vomiting, and their Head aked cruelly for the most part, Sweat difficultly succeeded, which being often partial and quickly broke off, rarely cured the Fit, but when the Sweat failed, they grew hot again, that scarce in eighteen or twenty four hours the Fit was finished in some. In the mean time, from the Blood being very fervent, the Phantasie was disturbed, that oftentimes a Delirium, absurd or idle Talking, Wakings, and high Inquietudes were stirred up during the Fit;

but the ſame being finiſhed, in the time between, ſtill a troubleſom Thirſt, a ſlow Heat, Languor of Spirits, and great Debility of ſtrength, with an Head-Ach, and a vertiginous Diſtemper, for the moſt part moleſted them. It was rarely found, for any to find themſelves indifferently well, as in a common Tertian, between the Fits. About the beginning of the Diſeaſe, the feaveriſh Fierceneſſes were ſomewhat more mild, which afterwards at every turn, leiſurely grew worſe, and then began with Cold and Shaking; to which nevertheleſs, after a long and very troubleſome heat, Sweat very hardly ſucceeded in moſt, ſo that the Fit rarely ended in its due temper. Within ſix or ſeven Periods, the ſtrength of the Sick was much caſt down, that being made languid and weak, they had an hard task to ſtruggle with the Diſeaſe; becauſe unleſs Nature were ſuccoured by Art, the Feaver ſtill prevailed, and rarely or never in a ſhort time, was it cured by a Criſis, or leiſurely remitted; but it brought the ſick into great ſtreights, by its long ſiege, and ſtill perſiſting, till the Blood being by its frequent deflagration made very liveleſs and watery, was unable to grow too hot in the Veſſels of its own accord, or to be enkindled more plentifully in the Heart, and then oftentimes became ſo dead, and wanting of Spirits, that being inſufficient for the continuing the Vital Lamp, it brought in Death. But ſometimes the Maſs of Blood being depraved, and made poor by this Diſeaſe, was able (tho hardly) to continue the half extinct Vital Fire, and to renew it by little and little, with Spirit and Vigor, in a long time; yet in the mean time, after the height of this Diſeaſe, when the blood being made more weak and impure, could not expel forth of doors this feaveriſh Matter, or aduſt recrements, by a critical motion, it often transferred it to the Brain; and therefore about the height of this Feaver, a torpor, and ſtupidity of Spirits, Sleepineſs, Vertigo, Tingling of the Ears, Tremblings, and convulſive motions, with a great oppreſſion of the whole Animal Faculty, were moſt often induced.

Men of a cold temperament, or in years, who were taken with this Diſeaſe, altho they were but little feaveriſh, were wont however to be in greater danger of Life; becauſe, in theſe, beſides the diſpoſition of the blood, not eaſily reducible, alſo what was gathered together in the fits, that was extraneous and not to be mixed, was hardly ſubdued, and difficultly ſifted forth of the Maſs of blood; wherefore, both the blood was ſtill more notably depraved in its Craſis, and in every Fit more infected by the impure mixture: Moreover, the nervous Liquor was greatly perverted from its due temper, and defiled moſt badly, by the aduſt recrements continually poured on the Brain. Therefore, when old men, melancholic, or otherwiſe ſickly perſons, fell into this Feaver, they became, preſently after its firſt Aſſault, ſtupified, and for the moſt part vertiginous: Tho in the Fits, the heat was not very ſharp and piercing, they were however very unquiet, and ſtill toſſing about, oftentimes they talked idly and at random; after a long burning, either no Sweat, or only partial, and often broke off, followed; whereby the Fit was not fully helped, but that in the whole intervals, the ſick were thirſty, and remained very ill, with a drineſs of the Mouth, a ſcurfineſs of the Tongue, and a ſuffuſion of a viſcous Filth. After ſome Fits, their ſtrength being exceedingly caſt down, they were wholly fixt to their Beds, or riſe only for a little while, could ſcarce ſtand or ſet a foot before another, to move from place to place, or able to walk: in the mean time, they laboured with a languiſhment, a difficult breathing, a nummedneſs of ſenſes, and a great debility of the whole nervous ſtock: The Urine in moſt was highly red, of a more deep colour, and of a thicker conſiſtency, than in a common Tertian: The Pulſe, whilſt the ſtrength was not wholly caſt down, for the moſt part was ſtrong and equal; afterwards. when the ſick became very languiſhing, it was weak and unequal, and oftentimes intermitting; to which alſo, conſtructures of the Tendons, and convulſive Motions in the Wriſts, being joyned, were for the moſt part Prognoſticks of Death. Thoſe who leiſurely being debilitated, declined towards Death, ſome little time before they died, lay for the moſt part without ſpeaking, or knowing thoſe about them, as it were ſtupid; and it rarely hapned in this Feaver, that any one about to die, was ſo perfect in their Memory and Intellect, as to diſpoſe of their Family-Affairs, or to take leave of their Friends. But it hapned to thoſe that eſcaped, from a deep languiſhment and almoſt deſperate condition, not quickly or ſuddenly to recover, from their manifeſt evil diſpoſition, but lying a long while wavering, ſtupified, and without ſtrength, that Nature at length, not but after a doubtful and difficult ſtrife, got indeed ſcarcely the better of the Diſeaſe, and then recovered ſtrength by degrees, and health lingringly and ſlowly.

If the Nature, and formal Reaſon of this Epidemical Feaver but now deſcribed, be demanded, we ſay, that this (as that of the former year) properly is an intermitting Feaver: for what commonly ſpread bore that figure; altho ſome here and there, more rarely, had it continual, which we ſhall by the way mention by and by. The Seed-plot or Seminary of this, need not be derived from the Air, being infected with any Infection, but rather its leading Cauſe is to be ſought, from the undue conſtitution of the Year, and from thence an indiſpoſition of our Blood being acquired. Becauſe, in the Spring and Autumn, intermitting Feavers

have

have yearly ſprung up and increaſed; to wit, for that our Blood, like to the Juice of Vegetables, is wont to be more lively moved than uſual, and to flower at thoſe times. Wherefore if the maſs of Blood, by reaſon of the foregoing ſeaſon, of the Summer or Winter, ſhould be altered from its due temperature, and ſhould contract either a ſharp or atrabilous diſpoſition, or of any other kind, its evil diſpoſitions begun before, are chiefly ripened about the Equinoxes; to wit, when the Blood more freely fermenting (if that it hath departed from its natural diſpoſition) doth not ſo eaſily ſanguifie, but that it will be apt to pervert the alible juice, poured to it, into an extraneous and feaveriſh matter. When therefore this year had not very much declined from a right Conſtitution (as not only the Dog-days going before, but) that the two Solſtices, and the Equinoxes, were wholly intemperate, it was no wonder if intermitting Feavers, more frequent than uſual, and thoſe noted with ſome unuſual Symptoms, did encreaſe about the Autumn. That therefore an intermitting Epidemical Feaver raged at this time, I judge it not to be attributed to the fault of the preſent Air, but to the Irregularites of the foregoing ſeaſon: yet from what Cauſes and Occaſions, ſome Symptoms proper to this Feaver, and diſtinct from the common Rule of intermitting Feavers, did ariſe, will be worth our Enquiry. I have already ſaid, that the proviſion, that made this Feaver ſo deadly, conſiſted in two things chiefly, *viz.* the temper of the Year, now extreamly cold, then upon it very hot, then that it had variouſly perverted the diſpoſition of our Blood, and had diſtempered the Pores of the Skin, with an undue Conſtitution. According to the Reaſons taken from either, I ſhall endeavour to explicate the Accidents of this Diſeaſe, and to aſſign the Cauſes of its Appearnce.

1. Firſt, We ſhall obſerve, that the Type of this Feaver was various, to wit, in ſome with a continual heat, in others with an eruption of Spots, but in moſt intermitting, and like a Tertian, and ſometimes (tho rarely) a Quotidian, repeating the Fits every day, or every other day: the Cauſe of this diverſity, we impute to the more ſtrong and potent morbific procatarxy of this Year, which produced in the Autumn, a more common intermitting Feaver than it was wont; wherefore, in ſome (perhaps indued with a more praved habit of Body) it ſtirred up Feavers ſomething malignant; and in whom it cauſed intermitting Feavers, according to the wonted manner of the Seaſon, it made them to be noted with a peculiar appearance of Symptoms.

2. Thoſe taken at this time with the Epidemical Feaver (whether it was Continual or intermitting) ſuffered preſently evil Diſtempers of the Head, *viz.* now they were wont to be infeſted with cruel Head-Ach, now with a Stupor, or too great Diſtraction of the Animal Spirits. The reaſon of this is, that the nervous Juice, as well as the Blood, by reaſon of the intemperance of the Year, was much altered from its due Craſis or Diſpoſition, *viz.* by nature ſweet and ſpirituous, and was become now heavy, and almoſt lifeleſs, now ſharp, and too much pungitive. Beſides, alſo, the Maſs it ſelf of the Blood very much contributed to this Evil; for whilſt it grew hot, the vaporous Effluvia. which ought to have been diſperſed outwardly, by reaſon of the Pores being ſhut up, were poured upon the Brain, and Membranes of the Head; and by reaſoe of this kind of ſtopping, impreſſed almoſt upon all, ſweat hardly, and not but partial, and often interrupted, ſucceded in the fits; hence alſo in the height of the Diſeaſe, a perfect Criſis, or ſpontaneous, rarely or never happened to cure it; but inſtead of this, if the buſineſs was committed to Nature, the aduſt Matter, or Recrements gathered together in the Blood, were transferred to the Head, and there raiſed up now the ſleepy Evil, now Phrenſies, and thoſe long and ſtubborn.

3, That the Fits ſometimes begun without cold or ſhivering, but with a troubleſome heat, and were prolonged with a difficult Sweat, partial, and often interrupted; then foraſmuch as the ſame being finiſhed, the ſick began again to wax hot, that the Fits were not finiſhed without a long evaporation of a dry breath; the cauſe was, the too ſharp and bilous diſpoſition of the Blood, whereby when it grew turgid, it was ſtuffed rather with aduſt Salt and Sulphur, than a ſerous Juice, and preſently conceived an enkindling, without any previous Flux of nitrous Matter; and therefore for want of Serum, and by reaſon of the Pores being ſhut up, its deflagration was continued for a long time, almoſt only with a dry Exhalation, and ſcarce at laſt ended in a remiſſion. And therefore the interſtitia of the Fits were moſt troubleſome with Heat and Thirſt, Head-Ach, Vertigo, and other Diſtempers; becauſe the feaveriſh Matter, being heaped up in the Blood, was not all diſperſed by the ſeveral Fits, but part of it being left after the Fit, as it were extraneous and not miſcible, induced almoſt a continual burning.

4. It was obſerved, that thoſe diſtempered with this Feaver, preſently loſt their ſtrength and fleſh, that after a fit or two, they panted for breath, and being very weak, were not able to ſtand or go, without being led; when it is an uſual thing in an intermitting Feaver that is common, for the Patient to be very lively and chearful between the Fits: the reaſon of the Difference is, becauſe in this Feaver, the Maſs of Blood is both more

more depraved by the impure mixture of the degenerate Juice, and eſpecially, that the ſame is more perverted from its natural diſpoſition, and therefore, when it boils up leſs out of the fits, it yet ferments not rightly and equally in the boſom of the Heart: wherefore, when by any more quick motion, or agitation of the Body, the Blood is carried more impetuouſly into the boſom of the Heart, becauſe it is not there preſently enkindled, it both leaps forth of doors, and by its ſtagnation, cauſes the oppreſſion of the Heart, and great weakning of the Vital Spirits. By reaſon of this kind of dyſcraſie of the Blood, to wit, whereby it is made more unfit for due Fermentation and enkindling in the Heart, alſo ſome Beaſts, , and eſpecially Horſes, in the Spring-time, are made hard-breath'd, and very unapt to any rapid motion.

5. Laſtly, We are to enquire, concerning this Feaver, wherefore it ſpread chiefly in Villages, in leſſer Towns, and the Countrey, when Cities and greater Towns were leſs troubled with it. It might ſeem that this Diſtemper ſhould be excited from Marſhy Fogs, and other hurtful Vapors, plentifully heaped together in this or that Tract of the Air: but there is a better reaſon, for that the Inhabitants of theſe kind of places, being more expoſed to the Spring-cold, and then to the Summer-heats, might have contracted a greater Dyſcraſie of the Blood, and ſo a more apt diſpoſition to this Feaver. For in truth, the Inhabitants of the Country could ſcarce go out of their houſes, but they were expoſed to the Sun's beams, or the fervor of the heated Air. Beſides, Countrymen, Husbandmen, and ſuch as were accuſtomed to Labors (among whom this Feaver chiefly raged) from their immoderate toil in the Sun or open Air, alſo uſing a bad and ſharp Diet, ſooner acquired an aduſt and torrid diſpoſition of the blood, and ſo more apt for this Diſeaſe than Citizens and Townſmen, who lived an idle Life, and enjoyed wholeſom food, and moſtly continued within doors, and in refrigerating Shades. We may believe this Aſſertion, for that not only the Epidemical Feaver now raging, but alſo another of the Autumn before, excited by reaſon of the evil diſpoſition of the blood increaſed chiefly among the Countrymen, and Inhabitants of the Countrey: but the popular Feaver, which aroſe in the middle of the Spring, depending chiefly upon tranſpiration being hindred, moſtly infeſted Citizens and the Inhabitants of Towns; whilſt Ruſtical men, that were wont, by Labour and Exerciſe, to procure a more free breathing forth, remained free.

The general Prognoſtication of this Diſeaſe ſeems only to ominate or foretel the like evil almoſt to follow this, as followed the Epidemical Feaver of the former Autumn, to wit, the Augury being taken rather from the intemperance of our Blood, than from the evil of the Air) not the Peſt, but a Quartan Feaver might be feared to come upon it. As to the particular Indication, as Signs that promiſe Health or Death, I ſhall briefly mention them; and they chiefly reſpect the temper and government, either of the Blood, with the Vital Spirit, or elſe of the nervous Juice, with the Animal Spirit. If it be plainly indicated from the Pulſe, Urine, from Actions leſs hurt, and the appearance of other Symptoms, that the Blood, as to its feaveriſh diſpoſition, is not very much perverted from its natural temper; that in the fits it moderately burns forth; and in every Combat eaſily ſubdues the load of the feaveriſh matter, and wholly ſhakes it off from its company; that after ſome fits, the maſs of Blood is ſomewhat reſtored towards its due Temper; that it perverts little the alible Juice, and ſifts forth, with a more gentle riſing up, what is extraneous and not mingleable, and that if in the mean time, the other ſpirituous Liquor, rightly inſpires and waters the Brain and Nervous Bodies, that Sleep, Waking, Senſation and Motion are performed well, or at leaſt indifferently, all good is to be hoped concerning the ſick. But if it appears from the ſame Fountains of Indications, that the Blood hath acquired in this Feaver, a diſpoſition far removed from the natural, if it perverts much of the alible Juice, and then from its extraneous and incongruous mixture, the Liquor of the Blood is greatly diſturbed, and the Spirits driven into confuſion; if in the fits, the Blood too ſtrongly, and in a long time burns forth, yet doth not truly ſubdue the feaveriſh matter, or exclude the whole, but that by its impure mixture, it is ſtill more and (in every feaveriſh fit) more infected, and the Spirits being continually conſumed, it becomes poorer, we may pronounce the Life of the Patient to be in much danger. Beſides theſe, if the Vices of the Nervous Juice happen, that being altered from its due temper, or being too dull, and as it were lifeleſs, little actuates the Brain and nervous Stock; or being above meaſure ſharp, continually provokes the ſame into Convulſions and Diſtractions; and if beſides the vaporous Effluvia's continually falling away from the Blood, or the aduſt recrements being wont to be ſifted forth by a critical Sweat, ſhould be transferred into the Head, and there induce Lethargic or Phrenſical Diſtempers, the hopes of Health will be little, and we may fear a very deadly event.

Concerning the Cure of this Diſeaſe, the Intentions will come under three Conſiderations chiefly. Firſt, a quick reduction (as much as may be) of the Blood and nervous Liquor, to their natural tempers, or at leaſt a prevention of their too great depravation. Secondly, Concerning the right handling the fits of the ſick, it ought to be procured, Firſt, that leſs of

the

the degenerate Juice may be gathered together for matter of the fit: 2ly, that what is gathered together, may be wholly diſperſed by every fit, that thereby the ſick may be better in the intervals: Thirdly, that the body being altered for the better, the fits may be inhibited by Anti-feaveriſh Remedies. The third intention reſpects the Symptoms chiefly urging, which ſhould be timely oppoſed, whereby Nature, being not hindred, may reduce whatſoever intemperance may be contained in the Viſcera or Veſſels, may ſubdue and ſift forth the extraneous Matter, and at length may recover a lively force, and priſtine vigor.

Firſt, therefore, for the reduction and emendation of the Blood and nervous Juice, diverſe manners of Evacuations are wont to be exhibited in this Diſeaſe, about the beginning of the Sickneſs, with good ſucceſs. It appears plainly from modern Practice, that Vomitories are of more noted Uſe in this Diſtemper, than in a common Tertian: wherefore in a robuſt body, and prone to vomit, about the beginning of the ſecond or third fit, it is convenient to give an Emetic Medecine. The operation of this ſeems to be very helpful in this Feaver, foraſmuch as it more plentifully evacuates the filth from the Ventricle, and the yellow Bile from the Choler-bearing Veſſels; and becauſe it copiouſly preſſes forth the ſerous Juice from the Emunctories of the Nervous Stock, planted about the Pancreas and Inteſtines, and by provoking them, draws it out. Wherefore we obſerve, that from a Vomit being taken, the ſick do find themſelves better about the Diſtempers of the Head. A Purge (to whom a Vomit is not convenient) may be ordered inſtead of it; the day following the fit, alſo tho an Emetick have been taken, it may be well permitted after a fit or two: But yet only with gentle and benign Phyſic, let it be performed, which will not diſturb or too much move the Blood. We were wont in theſe Feavers, letting alone Diagridium or any Aloetic Medecine, only to give an Infuſion or Powder of Senna, Rhabarb, and yellow Saunders, with Tartar and Salt of Wormwood, and to celebrate this kind of Purgation not very long after the beginning of the Diſeaſe, but at other times to keep the Belly ſoluble with the frequent Uſe of Clyſters. Frequent Experience hath ſufficiently taught, that Letting of Blood is highly profitable in this Diſeaſe; for when by reaſon of the Pores in every one, being more ſtrictly cloſed than uſual, the Blood growing hot, by the Feaver, wanted Ventilation, the Letting of Blood ſupplies the place of a more free breathing forth, and prevents the reſtrained *Effluvia* from ſo readily ſuffuſing themſelves on the Brain and nervous ſtock. But this Remedy is chiefly indicated from the very fervent Blood, and more hot temperament, nor ought to be indifferently uſed to old men, Phlegmatic, and other very weak Perſons, unleſs perhaps in a ſmall quantity, that the maſs of Blood may be ſomewhat eventilated, and that the removal of the feaveriſh Matter into the Brain, may be hindred. If it be convenient to open a Vein, let it be done about the beginning of the Feaver, or at leaſt before the fourth or fifth fit, *viz.* before the Blood is made very lifeleſs by the frequent deflagration, and rendred too impure by the confuſion of the aduſt matter; becauſe, if Phlebotomy be made uſe of, , whilſt the Blood is highly corrupted, the Vital Spirits, and by that means the ſtrength of the ſick are more debilitated, nor yet is there any thing taken away from the power of the Diſeaſe, or from its Cauſe. There remains another famous way of evacuation, in this Feaver, to wit, Veſicatory Plaiſters applied to various parts of the Body; theſe are commonly obſerved to be ſo helpful, that thoſe that abhor and diſlike very much ſuch a Remedy, by the example of others being the better for them, have admitted them. By what means they ſeparate the Cuticula from the Skin, and lift it up like a Bladder filled with Water, or whether they preſs forth this watery and limpid humor, out of the Arteries, or out of the Nerves, is not in this place to be enquired into; yet that they are profitably adminiſtred in this Diſeaſe, beſides Experience, Reaſon ſeems ſomething to perſwade, becauſe it in ſome manner compenſates the want of Tranſpiration, by the large profuſion of this kind of ſerous Latex: Moreover, this kind of Remedy, as it were, opens the ways and doors, by which both the Blood, and nervous Juice, may forthwith ſend forth by a proper purging, the extraneous matter, confuſed with them; wherefore, in the Plague and Malignant Diſtempers, Veſicatories are eſteemed very profitable. Alſo it appears by common obſervation, that in this and other Feavers, frequent at the ſame time, they did prevent the more grievous Diſtempers of the Head, and were wont to help them, if they were brought in before: wherefore, Epiſpatic Plaiſters may be applied about the beginning of the Diſeaſe, for preſervation ſake, to Phlegmatic Perſons, Elderly People, and men of a more cold Temper; and they are wont profitably to be adminiſtred to ſeveral others, labouring with a Vertigo, Stupefaction, or cruel Head-ach, for the Cure of the ſame Diſtempers. But in Conſtitutions very hot, where with the defect of the Serum, the Blood is too much burnt, and if thoſe ſick of the Feaver are obnoxious to Wakings, or a Phrenzy, with intolerable heat, Bliſters ſeem then to be of little uſe.

For the mending of the temper of the Blood, and alſo the tenor of the Viſcera, at vacant times, when there is leiſure from purging, attemperating Remedies have place, and Digeſtives, which fuſe the Liquor of the Blood, and ſeparate its fæculencies, and as it were by pre-

precipitating them, thruſt them towards the Emunctuaries: For theſe ſort of intentions, are wont to be given Juleps, and refrigerating Decoctions, ſharpned with Spirit of Vitriol, of Salt, Tamarinds, or with the Juice of Oranges or Limons; forms of which choice enough are commonly to be had. Alſo for this end, acetous, ſaline, and ſhelly Powders are uſed, to wit, prepared out of Tartar, Salnitre, the fixed Salt of Herbs, of burnt Harts-horn, alſo the Claws and Eyes of Crabs. As for example, Take of Cream of Tartar drams three, of Salt of Wormwood dram one and a half; the Doſe half a dram, in an opening Decoction, twice in a day out of the fit. Or take of Cream of Tartar dram one, of the Powder of Crabs Eyes dram one, of purified Nitre half a dram, mingle them; let them be taken after the ſame manner. Or take of Harts-horn burnt drams two, of the Spirit of Vitriol, what the Powder will drink up, the Doſe is one ſcruple, it is of excellent uſe when thoſe in Feavers are infeſted with Worms. Theſe kind of Remedies promote the ſecretion of the feaveriſh matter, and alſo reſtore the almoſt deſtroyed ferments of the Blood and Viſcera.

The ſecond intention, *viz.* concerning the right handling the fits, comprehends more. Firſt, There ought to be inſtituted a right order of Diet, whereby the more full heaping up of the degenerate Juice, for the matter of the fit, may be inhibited; wherefore, they are only to be fed with thin Aliments, and they muſt wholly abſtain from Fleſh (or Broth made of it) Eggs, ſtrong Drink, and all rich Meats and Food whatſoever, and be contented only with Barly Broth, or Grewel, Panada, Whey, and ſmall Beer; for that a more plentiful Aliment is not digeſted, or aſſimilated, but loads the Ventricle, and being powred into the Blood, diſturbs its Liquor, and compels it to grow impetuouſly hot. In the beginning of the Fit, and the time of its duration, no food ſhould be taken, unleſs for the allaying of thirſt; But for the tempering of heat and thirſt, Juleps, and cooling Decoctions, and eſpecially ſmall Beer: and Poſſet-drink ſhould be granted. Secondly, a little before the coming of the fit is expected, a gentle Medecine may be adminiſtred, which may drive away the fit by preventing it, or make it more eaſie by procuring a Sweat: for this uſe the Febrifuge Potion of the moſt Learned *Riverius* ſerves well, of the Water of Carduus, with Oyl of Sulphur, and Salt of Wormwood: Or take of Cream of Tartar, of Salt of Wormwood, and the ſeeds of Nettles, each one ſcruple, let it be given in the Decoction of the Roots of Sorrel; when the Feaver begins to decline, and that the fits are a little more remiſs, proper Febrifuges, applied outwardly, often inhibit the comings of the fits. Yet in the mean time, ſo long as the fits of the Feaver return, the ſick are to be handled ſo, that in every fit, the feaveriſh matter heaped in the Blood, may be throughly diſperſed; wherefore, when Sweat hardly ſucceeds, it ſhould be a little excited by temperate Medecines: Alſo the ſick ſhould be kept in bed, with a gentle breathing many hours, nor quickly permitted to riſe; for I have often obſerved, that ſick perſons have been ſtill worſe, becauſe impatient of their Bed, they have put on their cloaths before the vaporous Effluvia were ſufficiently exhaled.

Thirdly, As to the Symptoms and particular accidents, wherewith the ſick are wont to be infeſted in this Feaver, it is ſufficiently provided for moſt of them, with Remedies, in the method of Cure hitherto deſcribed; again, thirſt, the heat of the mouth, the ſcurfineſs of the tongue, vomiting, the looſneſs, fainting, ſwooning, may be referred hither, very well the preſcriptions commonly uſed in other Feavers: But what may ſeem to require in this Diſeaſe a peculiar Method of healing, are chiefly the Diſtempers of the Head and Brain, with the nervous Stock, which not being timely helped, may ſoon put the ſick into great danger of Life: As to the Indications of theſe kind of evils of the Head, they are of a twofold kind; if it appears from a Stupefaction or Torpor, a Sleepineſs, Vertigo, or Head-Ach, that the nervous Juice is become too dull, and as it were vapid or lifeleſs, and therefore doth not ſufficiently actuate the Brain and nervous Bodies; beſides the Remedies already delivered, and eſpecially Veſicatories, Medecines full of a volatile Salt do chiefly help: wherefore Spirits of Harts-horn, and of Blood, alſo the Salts of them, are of excellent uſe; but if the nervous Liquor be too ſharp, or the effluvia ſuffuſed from the æſtuating Blood, drive the Animal Spirits into confuſions or diſtractions, Remedies of the ſame ſort of volatile Salt are adminiſtred with ſucceſs in a little ſmaller quantity. Beſides, a frequent letting of Blood, and aſſwaging Medecines againſt its Fervor, help much; as Emulſions, Whey, and ſimple Water, plentifully drunk; Opiats are cautiouſly to be given in this Feaver, for the Phrenſie being often allayed by them, is changed into a Lethargy, or a deep Stupefaction.

FINIS.

THE AUTHORS EPISTLE

(To the *Treatise of Urines*)

TO

Dr. Bathurst.

Worthy Sir,

THE *Inspection of Urines, and from them an investigation of directions concerning the Medicinal Practice, began to be esteemed among the Ancients, even from the first beginning of Medicine: for from hence for the making of judgments concerning the Sick, and for the chusing the most fit times for Curing, the great* Hippocrates *hath chiefly taken both his prænotions, and his precepts, so that that famous and to this day approved statute of old Medicine, to wit,* τὰ κέκρινε φαρμακεύειν, *to compose Medicine according to digestions, cannot be observed without rightly consulting the Urinal. Also this seems consonant to common reason, that for as much as we cannot search into the most intimate parts of the sick Body, as it were a Vessel shut up, judgment is sought from the infused liquor, washing all its parts, and taking from many some little parcels. For neither more certainly do the acidulous or Spaw-waters, shew the nature of the hidden Mine, through which they are strained, than Urines give testifications of the divers manners of dyscrasies of our Bodies, and their habitudes. Wherefore the Contemplation of this Excrement, (as vile as it is) hath grown to a Science, and hath exercised the ingennities of the most excellent Physicians, both Ancient and Modern. Concerning this thing there are many Books extant, writ with great diligence; in which are rehearsed the great differences of Urines, varieties of Colours, and diversities of Consistence, and their Contents exactly described, and distinct precepts are delivered for every excretion of them: Which indeed are esteemed by some of so great certitude, that from the inspection of the water, a signification is sought of any Disease, or of the part affected; yea of every accident concerning the sick. But in this the Common* People *are egregiously deceived, and still pertinaciously will be deceived, whilst they imagine the knowledge of every Disease, and the prognostication of it cannot be found out, but by inspecting the Urine; and esteem a Physician of little worth unless he undertakes to divine from the Urinal as from a Magical Glass. But indeed, as to what belongs to the Precepts, and Rules whereon the reason of Judgment by Urine doth depend, there are many collected by diligent observation, that are extant, and from thence establish'd with good Reason and Judgment: yet for as much as the signification of Urines is by some too largely extended to particular Cases, very many uncertain things interwoven, and some obnoxious to deceit, and others plainly false; therefore who shall confidently pronounce concerning the business of the Sick, by the judgment only of the Water, deserves rather the name of a jugling Quack, than of a Physician.*

But this Doctrine concerning Urines, abounds ſo ordinarily with errors, that the obſervations which belong to its practice, are either wrongfully made, or not well reduced into method. We may lawfully ſuſpect that the obſervations are not rightly made, becauſe perhaps from one or two particular caſes, oftentimes a general rule is eſtabliſhed. For Example ſake, becauſe ſome Hydropical people render a thin and watery Urine, therefore it is affirmed, ſuch ſort of Urines neceſſarily denote a Dropſie, when alſo in ſome other Diſeaſes ſuch like Urines are made; and ſometimes in the Dropſie, the Urines are thick, and full of redneſs. Alſo as it is moſt commonly received, that Urines on which a cream doth ſwim (as on water that hath Tartar boyled in it) doth denote a Conſumption, which is moſt uncertain, becauſe this ſign is more proper and familiar to Hypochondriacks than to Conſumptive people: And how many dye of Conſumptions without this? Beſides, what is generally aſſerted, to wit, that in all diſeaſes whatſoever, Nature doth make known the Diſeaſe by the Urine, is altogether falſe; becauſe ſometimes ſick people make their Urine like healthful people; and ſometimes thoſe who are very well in health, by reaſon of ſome accident (perhaps from the meats eaten) have ſuſpected Urine, varying from the natural ſtate or condition. As to what belongs to the method, or doctrine delivered by moſt, concerning Urines, they ſeem to be altogether Empirical, and nothing rational: for the naked differences of Urines are rehearſed, and are wont to be diſtinguiſhed according to their colour, conſiſtency and contents: thence are oppoſed to the ſeveral ſpecies of theſe pathologick ſignifications, collected only from more rare obſervations; when in the mean time, the cauſes of the appearances, nor of the preternatural alterations in the Urines, are not aſſigned, as they ought to be; nor is the ſignification of the Urines applyed to the Cauſes of Diſeaſes, but only to the Diſeaſe or Symptom; and therefore it is moſt often deceitful, and uncertain; becauſe the ſame morbifick Cauſe, and ſignification of the ſame Urine, may in like manner mediately reſpect at once divers Diſeaſes, and Symptoms. As for Example, a thin and watry Urine, moſt often immediately denotes Indigeſtion, or a defect of Concoction in the Viſcera: nevertheleſs, by reaſon of that condition of Crudity, the Green-ſickneſs in Virgins, ſometimes the Dropſie, or the white watery phlegmacy, ſometimes Head-aches, and many other diſeaſes ariſe. But the task which you have required of me, Worthy Sir, to wit, that the notions which in times paſt we have diſcourſed together, and conceived concerning Urines, as it were collected notes, and what have ſince fallen under my own knowledge, by my proper ſtudy and obſervation, concerning this thing, ſhould be fram'd into a little Treatiſe, and that I ſhould write a plain and new method of Urinoſcopie. I confeſs the work greater than can well be performed by our own proper ſtrength: however, I have reſolved as much as I am able, to obey you therein. But that a Doctrine or Method concerning Urines may be inſtituted, beyond the vulgar and plainly Empirical manner of Philoſophiſing, there ſhall be theſe two heads of our Diſcourſe. To wit, Firſt that the Anatomy of Urine may be delivered, of what elements and parts it conſiſts; and alſo its geneſis in our Body; to wit, by what Concoction this kind of Liquor is made, and then by what ſecretion of ſome Particles from others. Secondly, That the inſpection of Urines in the Urinal may be truly unfolded, and what may be the Rules, and the Certitude of Uromancy, or divination of the Urine.

OF

OF URINES.

CHAP. I.

Of the Elements and chief Accidents of Urine.

WHEN the Liquor of the Urine, being either freſh rendred from the body, or putrified by a long digeſtion, is expoſed to a ſpagirick Analyſis, it is wont to be reſolved into theſe parts or principles: In the Diſtilling, Firſt, aſcends whatever of a vinous ſpirit is in it, diluted with water; but yet in ſo very ſmall quantity, that it is not eaſily to be perceived by the taſte it ſelf. To this follows a watry liquor, large enough in proportion, with which are mixed ſome more looſe particles of Salt, and Sulphur eſpecially. Thirdly, There is ſtilled forth a very penetrative water; which is commonly called the ſpirit of Urine, but in truth almoſt without any vinous ſpirit, and is chiefly phlegm highly ſharpned with Salt, and therefore it aſcends laſt, as in the diſtillation of Vinegar: but foraſmuch as the ſalt of Urine is volatile, but that of Vinegar only in the Flux; therefore the liquor ſtilled forth, which is greatly impregnated with its particles, is very acide: That which is imbued with the ſaline Particles of the other, is exceeding ſharp and pricking. It is a ſign that this kind of Spirit of Urine (as it is commonly known) ows its ſharpneſs chiefly to the Salt, becauſe, though it be moſt ſubtil it will not take fire, but being put to it extinguiſhes it. After the humidity is wholly exhal'd, another portion of Salt remains with the Earth of the cucurbit; to which if a more hot fire be made, that Salt will be ſublimed into the Alembick, and the earthy feces only remain. This kind of Anatomy of Urine plainly ſhows, that the Elements of which its liquor is compoſed, are a great deal of Water and Salt, and a little of Sulphur and Earth, and a very little of Spirit.

The ſaltneſs in Urines is perceived by the taſte and touch; it comes neareſt to a Nitrous ſalt in ſavour: It is drawn indeed from ſaline Particles of things eaten, which being more plentifully exalted by the concoction in the Bowels, and the circulation in the Veſſels, for the moſt part go into a Volatile Salt. That is truly Salt and Spirit, by reaſon of the long accompanying of either together, are gathered into a moſt ſtrict bond; and therefore it happens, that the Salt it ſelf otherways fixed, is carried up on high, and rendred able for motion, as it were by the wings of the other. Urines contain in them more or leſs of Salt, according to the diſpoſition of our body, and have it either volatile or fixed, which are therefore of a divers colour and conſiſtency.

That there is Sulphur contained in Urines, their quickly putrifying, and ſtink, ſufficiently teſtifie: it ariſes from the fat and ſulphureous Particles of Meats, in the concoction being moſt minutely broken, and boyl'd with the ſerum and ſalt; ſo as alſo there is leſs plenty of Spirit in it, than is in Blood, Soot, or the Horns of Animals: wherefore in the diſtillation of Urine, there aſcends nothing almoſt of an oylie form or fat. But indeed, whilſt the blood is circulated in the Veſſels, the ſpirituous and ſulphureous little bodies, which fall away from it, do for the moſt part evaporate out of dores; in the mean time, the ſaline recrements, and the watery, chiefly conſtitute the Piſs: nevertheleſs, Urines do always participate a little of ſulphur, but its quantity and proportion, is diverſly altered according to the various degrees of Concoction and Crudity, and thence alſo the colour and conſiſtence receive many mutations in Urines.

That there is but a very little of vinous ſpirit in Urines, the defect of it in the liquor diſtilled forth, alſo the ſoon putrifying of the Stale do teſtifie: but that there is ſome, the inteſtine motion of the Particles in the Urine doth argue, to wit, the departure of the thin from the thick, and the ſpontaneous ſeparation of ſome parts from others, and a collection of them into a ſettlement: beſides, the ſaline Particles (for that they are made volatile) are married to ſpirituals, and ſo they are of a more ready motion, and energy; yet according to the divers plenty of Spirits in Urines, and their power, there ariſe divers manners of hypoſtaſes and ſettlements; alſo the Urines themſelves, ſooner or ſlower putrify.

The watry part of the Urine far exceeds the reſt in quantity, and is greater than they by almoſt a ſixth part: it is not ſo ſimply drawn forth by diſtillation, but that ſome Particles of Salt and Sulphur (foraſmuch as they are volatile) aſcend with it, and impart to the water an ingrateful ſtink: the potulent matter, copiouſly taken with aliments, affords an original to this; which of what kind ſoever it be, before it is changed into Urine, lays aſide its proper qualities, and acquires others; for truly, from the aſſumed liquor, there is nothing ſincere almoſt left in the Piſs, beſides meer humidity.

That there is earth, and muddy feces to be had in Urines, its diſtillation, or evaporation ſufficiently declares: for when the reſt of the parts are exhaled, the earth as it were a *caput mortuum*, will remain in a moderate quantity in the bottom: Foraſmuch as in the nouriſhing juice, there is required ſomething ſolid beſides the active principles of ſalt, ſulphur and ſpirit, whence the bulk and magnitude of the body grows; the recrements of this, *viz.* the earthy feculencies, are plentifully diſſolved in the ſerum, and contribute to it a thick conſiſtence and contents: but theſe ſhew themſelves after a divers manner, according to the ſtate of Concoction and Crudity.

Theſe are the principles which conſtitute the body of the Urine, alſo into which it is eaſily reſolved, by a Chymical Analyſis: out of the divers changes, and various contemperation of theſe, the other accidents of Urine ariſe, *viz.* Quantity, Colour, Conſiſtency, and Contents, which are as to the ſenſe the moſt notable concerning it, and the chief objects of the rendered Urine: For when there is nothing beheld beſides in the Piſs, they conſtitute theſe firſt *Phænomena*, in which rightly ſolved, conſiſts the whole Hypotheſis of this Science: Wherefore we ſhall ſpeak in the next place, concerning theſe, and firſt of the Urine of healthful People, what its quantity may be, how coloured, with what conſiſtence and contents indued; and together ſhall be unfolded, out of what mixture of Elements, and by what Concoction in the *Viſcera*, and Veſſels, each of theſe depend. Secondly, ſhall be ſhewn how many ways the Urines of Sick People vary from the ſquare or Rule of this of the Sound: and I ſhall endeavour to aſſign, for the ſeveral differences of them, proper Cauſes of their alterations; and theſe ſhall conclude our firſt propoſition in this diſcourſe, *viz.* the Anatomy of Urine.

CHAP. II.

Of the Quantity and Colour of the Urines of Sound People.

THE Quantity of the Urine in Sound People, ought to be a little leſs than the humor, or liquid ſubſtance daily taken, for moiſt and drinkable things daily taken, are the matter it ſelf of which Urines are firſt made: But theſe (hunger and thirſt urging) are more plentifully required, both that they may ſufficiently waſh the maſs of the Chyme, by which means it may rightly ferment in the *Viſcera*; and that they may ſerve for a Vehicle, both to the Chyme, whereby it may be conveyed to the bloody Maſs, and to the Blood it ſelf, that it might be circulated in the Veſſels without thickening; and to the Nervous Juice, whereby it might actuate and water the Organs of Senſe and Motion: when the ſerous *Latex* by this means hath beſtowed whatever it hath almoſt of Spirit and Sulphur, for nouriſhment, Heat and Motion, it gives way to a new nutritious humour; and it ſelf as unprofitable, being ſecluded from the Blood, by the help of the Reins is ſent away. The nouriſhing liquor, which will at laſt be changed into Urine, of its own nature is divers, *viz.* now watry, now impregnated with Spirit, now with Salt and Sulphur, and according to the various forces of this or that Element in it, Urines are wont to be ſomewhat altered: However all liquors taken in at the mouth, do not paſs thorow our body whole and untouched; but that they undergo mutations in various parts, and loſe a little portion of their quantity, before they are made into Urine: For the *Latex* or Humour to be converted into Urine, is firſt of all received into the Ventricle, (for I aſſent not to *Reuſner*, who affirms the ſame falling for the moſt part on the Lungs, to cauſe the more quick making water after drinking) whilſt that it ſtays in the *Ventricle*, it is there boyled; alſo impregnated with Salt and Sulphur of its own, or from more ſolid Aliments diſſolved: then very much of it is confuſed in the blood, with the nouriſhable juice, which when it is a long time circulated, from thence receives a farther tincture of Salt and Sulphur, according to the various temper of the blood, and its inkindling in the Heart: Hence ſome portion of it is derived with the Animal Spirit, to the Brain and nervous ſtock; and afterwards from thence, being made lifeleſs and weak, is laſtly reduced into the boſom of the blood; after that it hath beſtowed on the Blood and Nervous Juice, whatever of generous or noble is conteined in the Serum, alſo no ſmall quantity is conſumed by ſweat and the other emunctories; what remains, whilſt that the Blood continually waſhes the Reins, a precipitation being made, either by a ſtraining or force of a certain ferment, it is there ſeparated from the Blood, and from thence paſſes thorow the Ureters into the Bladder, and ſo is carried forth of doors.

From

From the origine and luſtration of the *Serous Latex*, but now deſcribed, it plainly appears, that the Urine ought to anſwer to the quantity of the liquids taken, in ſomewhat a leſſer proportion, perhaps under a third part; which plainly ſhews the diſpoſition and ſtrength of the *Viſcera* ſerving for Concoction, as alſo the temper and diſtribution of the blood it ſelf, and after a ſort, of the nervous juice; moreover it carries with it ſigns of the affections of the Urinary paſſages. The quantity of the Urine declines often from this Rule, ſo that ſometimes it ſuperabounds, alſo ſometimes is deficient: and either for a ſhort time, may conſiſt with a diſpoſition not much unhealthful; but if theſe kind of diſtempers continue long, they argue a ſickly condition. Concerning theſe we ſhall ſpeak among the appearances of the Urine in a diſeaſed condition of the Body; we ſhall now next conſider the colour of a ſound Urine.

The Urine of Sound People, which is rendred after Concoction is finiſhed in the Body, is of a Citron colour, like Lye a little boyled: which without doubt proceeds from the Salt and Sulphur of the nutritious juice, and the Blood, diſſolved in the Concoction, and boyled in the Serum. This colour doth not ariſe only from Salt (as ſome would have it) becauſe the Liquor impregnated with Salt, unleſs it be evaporated to a certain thickneſs, will not grow yellowiſh: Alſo Salt of Tartar, being diſſolved by melting, continues ſtill clear. What may be objected concerning the Lye of Aſhes, I ſay, there the whole Sulphur is not conſumed by burning, but the Citron colour ariſes from ſome ſaline Particles, and others Sulphureous burnt, and ſticking together in the Aſhes, and then infuſed or boyled in the liquor. Neither doth the Urine of ſound People acquire this ſame colour from Sulphur only, becauſe Sulphur in a watry Menſtruum, is not diſſolved unleſs by the addition of Salt, nor will it give any tincture of it ſelf; but if Salt of Tartar and common Sulphur be digeſted together in water, or if Antimony be boyled in a ſaline Menſtruum, both liquors will by that means grow yellow like Urine; after the like manner, the ſaline and ſulphureous Particles of Aliments, being incocted and moſt minutely broken in the Serum, by a Digeſtion in the *Ventricle* and *Inteſtines*, and by a Circulation with the Blood in the *Arteries* and *Veins*, impart to it a Citron Colour.

This kind of diſſolution of Salt and Sulphur, by whoſe means the Urines are made of a Citron Colour, is firſt begun in the Bowels; and afterwards perfected in the Veſſels, and very much depends upon the Concoction performed in the *Ventricle* and the *Inteſtines*: For here, by the help of heat and of ferments, the Aliments taken are chiefly ſubdued; the bond of mixture being broken, the ſaline and ſulphureous Particles being moſt ſmally broken, and made ſmall, go into a milkie Cream, and from thence the Serum remaining after that Concoction and Diſtribution of that milkie juice, becomes of a Citron colour: after the ſame manner, as when the Salt of Tartar and common Sulphur being diſſolved together, and mixed with ſome acide thing, indue a milkie colour; then the contents being ſeparated by ſetling, the remaining liquor grows yellow like Lye. If that the aliments, by reaſon of an evil diſpoſition of the *Ventricle*, are not rightly digeſted in the firſt Concoction, as in the *Longing Diſeaſe* or *Pica*, the *Dropſie*, and other ill diſpoſitions of the Bowels, uſually comes to paſs, the Urine alſo is rendred crude, clear, and almoſt inſipid, like Fountain water; but if by reaſon of the ferments of the *Viſcera* being more than duly exalted, or otherways depraved as in the *Scurvy*, *Hypochondriac* diſtemper, or *Feveriſh* intemperance, the Particles of things eaten are too much diſſolved in the firſt Region, by that meanes Urines are rendred red and thick.

The *Serum*, as hath but now been ſaid, being imbued with a Lixivial Tincture in the firſt Concoction, and confuſed in the Blood, ſo long as it is circulated with it, it is yet further concocted, and acquires a more deep colour; for the particles of the Blood being roaſted and ſcorched, although for the moſt part they are laid aſide into the Gall bag, yet being in a manner boyled in the Serous *Latex*, they heighten its colour; hence the Concoction being ended, the Urine which is firſt made, is more pale, and that which is laſt, more red. That which is made after long faſting, is yet more high Coloured. Where the Blood is more cold, as in Cachectical people, the colour of the Urine is made leſs; where the Blood grows raging with a feveriſh Heat, and is roaſted, the Urine grows highly red.

Concerning the Urines of ſound people, it is worth obſervation, that which is made after plentiful Drinking, hath no tincture, but is pale like water; of which we ſhall enquire, by what means the Serous *Latex* ſo ſuddenly ſlides away out of the *Ventricle*, (contrary to what is vulgarly believed) and paſſing thorow all the Chyliferous paſſages, then the Veins, Arteries, the boſom of the Heart it ſelf, and the turnings and windings of the Veins and Ureters, is put forth of the Body within ſo ſhort a ſpace: moreover, how it comes that the Urine being ſo precipitately made, contrary to moſt other things, is not only changed into no Colour in its paſſage, but it alſo loſes its own proper colour: For as the Proverb is, *Our Drink goes thick in, and comes forth thin:* or *We Drink thick Beer, and Piſs clear.*

Concerning this we ſay, that beſides the long wandring of the nouriſhing juice, to wit, whereby, after ſome ſtay in the *Ventricle*, it ſlides into the *Inteſtines*, and from thence thorow the milkie Veſſels into new paſſages, and thence is carried into the Veins (which carrying about cannot be quickly performed) it is moſt likely, that there is another nearer paſſage of the ſame nutritious Juice, whereby indeed it may be conveyed immediately, and without delay, to the Maſs of Blood, and perhaps to the nervous Liquor; and therefore, after faſting, there immediately follows a moſt quick refection of ſtrength and ſpirits, after Eating, and eſpecially after Drinking; which indeed cannot be thought to be made by the Spirits and Vapours; alſo from ſuch drinking the Urine is preſently rendred, and indeed ſooner than it can be

be thought, that the Maſs of the Chyle can be ſent out of the boſom of the Ventricle; wherefore, it is not improbable, that when the Alimentous Liquor is entred the Ventricle, preſently the more thin portion of it, which conſiſts chiefly of Spirit and Water, is imbibed by its Spongeous Membranes; and from thence being inſtilled into the little mouths of the Veins, it is preſently confounded with the Blood flowing back towards the Heart. For of this opinion (though not very ſtubbornly) I always was, *That the Chyme was in ſome meaſure immediately derived from the Ventricle, and Inteſtines by the branches of the Vena Porta, into the Maſs of Blood*; and as the milkie paſſages carry it about by a long compaſs, whereby it may be inſtilled into the deſcending Trunk of the *Vena cava*; ſo that it may be carried in a more near way, *viz.* into the aſcending Trunk of the ſame, by theſe Veſſels; foraſmuch as the Blood being made poorer in its Circulation, returning from either part, before it had entred the heart, it ought to be refreſhed with a new juice, whereby it might more lively ferment in the boſom of the heart; but foraſmuch as the much greater part of the Blood is carried upwards, ſurely it may ſeem agreeable to truth, that at leaſt ſome portion of the nouriſhing Juice may be added to this, as it were a ſuſtenance, it being before burnt forth, and almoſt lifeleſs, for its new inkindling in the heart. The Arguments that ſeem to perſwade to this, not of light moment, I could here heap together, but I ſhould ſo divert far from our propoſition: wherefore, that we ſo ſuddenly make a wateriſh Urine after Drinking, I eſteem to be done after a manner as was but now ſaid; therefore the Liquor that is carried ſo haſtily from the Aliments to the Maſs of Blood, paſſing thorow the ſo narrow windings (as are the Membranes of the *Viſcera*) being drawn as it were by diſtillation, the more thick matter being rejected, conſiſts almoſt only of Water and Spirit; with which indeed it refreſhes the vital Spirits, and dilutes the Blood; about which task, when the ſpirituous part is conſumed, the watry Latex, becauſe of its plenty, being heavy and troubleſome, is continually ſent away by the Reins; and when it comes from the Ventricle, not yet imbued with Salt and Sulphur, nor is long circulated with the Blood, that it might by that means acquire a lixivial tincture, it is rendred thin and clear.

CHAP. III.

Of the Conſiſtency and Contents of the Urine of Sound People.

SO much for the Quantity and Colour of Urines, which proceed from a ſound Body; but as to what belongs to the Contents, we muſt know, that there ought to be nothing beſides the Hypoſtaſis in a ſound Urine; but what this is, and by what means it ſinks down, remains to be unfolded in the next place.

So long as the Maſs of Blood, being fuſed with the ſerous and nouriſhable humour, is continually circulated in the Veſſels, from it a certain nutritious juice is made, by a perpetual digeſtion, which being put continually to the ſolid parts, goes into nouriſhment: This firſt of all is digeſted into a glutinous humour, like the white of an Egg, afterwards into thin Filaments or Rags, which being interwoven in the Pores, and little ſpaces of the ſolid parts, ſtill afford to them an increaſe of new ſubſtance; but whilſt the Serum being mixed with the Blood, waſhes all the Regions of the Body, it ſucks up into it ſelf a certain ſuperfluous portion of this laſt Aliment, to be lay'd on the ſolid parts, and carries it forth of dores with it ſelf; and this it is that conſtitutes the Hypoſtaſis or ſettlement in Urines; wherefore ſo long as this is preſent, it indicates how far Concoction and Nutrition in ſome meaſure is performed, and is accounted a laudable ſign; its abſence ſhews Crudity and Cachectical people, or a *Dyſcraſie* in Fevers; it conſiſting of ſmall Threads or Filaments, is diſperſed at firſt thorow the whole body of the Urine, and then is collected into a little Cloud, by this means. Theſe Filaments or Threads, are long, and ſmooth, alſo indued with ſome ſharpneſſes like Brier-pricks, that from thence being ſhaken about, they eaſily lay hold of one onother, and are faſtned together; even as if unto an Urinal full of water, you ſhould caſt many Hairs, and then by ſhaking about the Veſſel, the hairs at firſt ſwimming diſperſedly, in a little time would lay hold on one another, and be collected into a little bundle; after the ſame manner (as it ſeems) the little threads which conſtitute the Hypoſtaſis or ſettlement being variouſly here and there agitated by the Colour and Spirits implanted in the Urine, intangle and thruſt upon one another, until they gather into one little Cloud by the mutual knitting of all together; and becauſe theſe Filaments are compacted, and more ſolid than the other Contents of the Urine, they ſink towards the bottom with their weight.

It is very likely, that theſe kind of Filaments, make the Hypoſtaſis in the Urines of Sound People, for that the Blood being well conſtituted, and diſpoſed to nouriſhment, is very much ſtuffed with Fibres, or white Filaments: becauſe, when a Vein is opened, if the Blood let out be received into warm water, it will be conſpicuous to any one; for the red thick ſubſtance being diluted with the liquor, theſe

ſmooth

ſmooth and white threads ſwim in the water; wherefore it ſeems, that ſome of theſe thin or ſlender rags, being ſnatch'd away with the ſerous juice, are the matter of this cloud ſubſiding in the Urine; wherefore in Cachectical people, by reaſon of Crudity, the Blood being very wateriſh, and unfit for nouriſhment, is deſtitute of theſe well labour'd Fibrils; alſo in *Dyſcraſies*, when the nutritious humour, the Blood being too much ſcorched, is not rightly concocted into theſe kind of Filaments, the Hypoſtaſis in Urines is either wholly wanting, or is very confuſed and diſturbed.

It is ſaid to be a good and laudable Hypoſtaſis, which is of a whitiſh colour, of a round and equal figure, and ſinks towards the bottom, to which are required, Firſt, that that laſt Aliment be rightly labour'd, whereby the Filaments may become white, ſmooth and ſolid, like to ſlender Fibres. Secondly, That the Urine be ſufficiently ſtrong in ſpirits, which (as is beheld in the growing hot of Muſt, or new Wine) may agitate, and compel here and there all parts. Thirdly, that the liquor be not too thick, nor that its Pores be firſt poſſeſſed by ſtrange bodies, whereby the motion of the contents may be hindred, but that a ſufficient ſpace may be left, for the free agitating and toſſing about theſe kind of Particles.

If the ſubſtance be red, it is a ſign that that laſt Aliment is ſcorched and burnt, with too much heat; wherefore ſuch a ſediment, for the moſt part is in the beginning of a Feavour, ſo long as the Coction in the Viſcera and Veſſels, is not wholly perverted; if the Hypoſtaſis be broken and unequal, it is a ſign that the nutriment deſtinated for the ſolid parts, is not rightly and equally concocted, and that its Particles are not homogene, and alike in every part: wherefore the Filaments do not cohere together, but theſe with thoſe, and they with others, are entangled apart; hence ſome more thick deſcend towards the bottom, and others more light ſwim upon the top. When the Hypoſtaſis does not wholly ſink down, but hangs all of it, either in the middle or upper Region, that happens, becauſe that thoſe Filaments are not perfectly laboured, nor ſolid and compact, but more rare and ſpungy, or becauſe the liquor is thicker, and more impregnate with Salt and Sulphur, and therefore like Lie it ſuſtains ſome weights, which otherwiſe would ſink to the bottom. Sometimes the Hypoſtaſis is wholly wanting, in ſound people, after long faſting, immoderate labours, or copious ſweating, the matter being wholly conſumed into nutriment, or evaporated by ſweat; in Fevers, by reaſon of the very depraved condition of the Blood; alſo in the *Pica*, *Cachexie*, and other Diſtempers of that kind, by reaſon of the great Crudity.

Concerning the conſiſtency of the Urine in ſound people, there is not much worthy conſideration to be met with: It is wont to be of that ſort, as midling Beer is, being purified by a long Fermentation; or Lye a little boyled, *viz.* the watry liquor of the Urine, ought to include in its Pores and paſſages, a great many Particles of Salt and Sulphur, moſt ſmally broken and diſſolved; and beſides a little of earth, divided very exceeding ſmall, and diſperſed thorow the whole body of the Piſs, if the conſiſtence be thinner than it ought, as it is in clear, or limpid Urines, and watry, it is a ſign of indigeſtion and crudity; that the Aliments are not fully overcome, and concocted; but if the Urine be thicker, and cloſer than it ought, it is a ſign, that the body of the liquor, is filled with preternatural Contents. But of theſe elſewhere, when we ſhall ſpeak of the Urines of the ſick.

Thus far of Urine, foraſmuch as it is an Excrement, and ſign of Concoction in a ſound body (truly performed in the Viſcera and in the Veſſels) the quantity or bulk of which is to be determined by the potulent matter; the colour Citron, from the diſſolved Salt and Sulphur, and boyled in the Serum; the Hypoſtaſis or Contents depend upon the Filaments, elaboured in the Blood, for the nouriſhment of the ſolid parts; the conſiſtency on the Salt and Sulphur, together with the Particles of Earth, filling the Pores and paſſages of the ſerous liquor. It next remains, that we treat of the Urines of Sick People: in which alſo, the Quantity, Colour, Contents, Conſiſtence, and ſome accidents beſides, offer themſelves to conſideration.

CHAP.

CHAP. IV.

Of the Quantity and Colour in Urines of ſick People.

IN a Morbous proviſion of Bodies, or Sickly eſtate, the quantity of the Urine does not exactly quadrate with the proportion of the liquid things taken; for ſometimes it wants of its due meaſure, and ſometimes exceeds it. When the Urine is much leſs than the drinkable things taken, the reaſon is, becauſe the watry Latex either ſtays ſomewhere in the Body, or is diverted by ſome other way of Excretion, than by Urine: if it remains within; Firſt, it is either heaped up about the Viſcera, and their Cavities, and ſo is ſtay'd now in the Ventricle, more than it ought to do, and induces by the diſtention of it, troubles, with ſpitting; but more often, it is laid up in the hollowneſs of the Abdomen, and ſometimes of the Thorax and head, and there is wont to cauſe Hydropic Diſeaſes. Or, Secondly, the Serum ſtagnates in the Veſſels, and ſo increaſes the bulk of the Blood, and NerVous Liquor, and notably perverts its motion; whence Catarrhs, Rheumatick diſtempers, and often Palſies and Convulſions are cauſed. Or thirdly, this watry humour is fixed in the habit of the body, and ſo creates a ſwelling up of the whole body, or of ſome parts. Or fourthly and laſtly, it is obſtructed in the urinary paſſages, by the Stone, or thick matter, as it were a dam oppoſing it; and cauſes in thoſe parts pains and Convulſions, and a fulneſs of the Serum in the whole body. When the ſerous water is other ways beſtowed, the Patients are for the moſt part prone to frequent and troubleſome Sweats, or almoſt to a continual Looſneſs.

The diſtempers therefore which the ſmall quantity of the Urine is wont to indicate, are ſometimes the ſwelling up of ſome of the Viſcera, and a heaping up of water in them, ſometimes Catarrhal diſtempers, ſometimes evil diſpoſitions of the nervous ſtock: ſometimes an Anaſarca and watry Tumors: and ſometimes the ſtony diſpoſition of the Reins and Bladder. And ſometimes alſo the diminution of the *Urine* is the effect and ſign of ſome other preternatural evacuation, *viz.* an immoderate excretion of Siveat, Lask, or ſome other thing. To deſcribe here exactly all the ſubſiſtences of the ſerous Latex, either in the body, or the cauſes of it other ways excreted, and the manner of doing it, were to transfer hither almoſt the whole matter of Pathology; for many and divers are the occaſions and circumſtances, whereupon this Serum is heaped up in this or that part, and ſubſiſting in the body, diminiſhes the quantity of the Urine; but for the moſt part the principal and moſt frequent cauſe of this conſiſts not ſo much in the fault of the Liver, Spleen, or Reins, as of the blood it ſelf: to wit, a copious and free making of Urine, as alſo its ſtay in the body, and only made in little quantity, depends chiefly on the temper of the blood, and either on its kindling, or fermentation in the heart: for if the blood be ſtrong in rightly exalted principles, (*viz.* Spirit, Sulphur, and Salt) it grows very hot in the Veſſels, and ſo the frame of the liquor being looſe enough, it is duly kindled by the ferment of the heart; and almoſt ſpiritualizes the whole, paſſes through all parts with heat and a rapid motion, without ſtopping; and whatſoever is ſuperfluous and volatile, evaporates out of doors: and whilſt the blood is rarified, and boiling with heat, paſſes through the Reins; what is ſerous is eaſily ſeparated, either by the ſtrainer of the Reins only, or (which is moſt likely) by a coagulation, and is as it were precipitated from the remaining maſs of the blood. The ſame thing almoſt happens after this manner to the blood, as we may obſerve in Milk, *viz.* whilſt it is warmed, and grows hot, it moſt eaſily goes into parts, and its Serum is moſt eaſily ſeparated by the leaſt drop of Runnet, or Coagulum put into it: but if you pour much more ſtrong and ſour ferment into it, when it is cold, a precipitation will hardly follow; ſo if the blood becomes through an evil conſtitution, or ill manner of living, more cool and watry, that being leſs enduced with active Elements, it grows but dully hot, and is but little kindled in the heart, it is circulated very ſlowly and difficultly in the Veſſels; paſſing through the Pores and paſſages of the Viſcera, it cleaves a little to them, and leaves ſomething behind it; whence are gotten every where Obſtructions and Tumors; alſo the blood by this means becoming viſcous and cool, and ſo unfit for precipitation, or percolation lays aſide leſs readily its excrements in the Reins; but leaves them every where in the body, becauſe it hardly, and not without the reſidence of a certain humor, is circulated. Wherefore in this ſtate, thoſe things that move the blood very much, as exerciſe and a more quick motion; or alſo ſuch as may fuſe it, as it were with a Coagulum or Runnet, as are ſharp things, and preparations of Salts, will more freely provoke Urine.

It ſometimes happens, that the Urines of the ſick are made in a large quantity, and very profuſe, that a day and a nights ſpace, they make perhaps twice or thrice as much water as the Liquids they have taken; the cauſes of which diſtemper are alſo various, and the ſignifications very divers; if after the ſuppreſſion in of Urine, or its quantity formerly leſſened, if in Hydropick diſtempers, Rheumatiſms, or paſſions of the nervous ſtock, or in the Criſes of Fevers, a flowing down of the Urine follows, either of its own accord, or by the uſe of Diureticks, it denotes a Cure of the diſeaſe, or preternatural diſpoſition, or at leaſt a declining of it. But if (as I have often obſerved) in a lean and weak conſtitution (without any of the previous

previous diſtempers but now recited) the Urine exceeds much the Liquids taken, and from thence a great debility of the whole follows, this indeed ſignifies an evil diſpoſition, with a tendency to a waſting or Conſumption. I have known ſome women of a tender and moſt fine make, who ſometimes being ill, for many days, were wont daily to make water in a great abundance, (exceeding twice the Liquids taken) and that watry and thin, without contents or ſetlement; at which time they have complained of a languiſhing of ſtrength, difficult reſpiration, and an impotency to motion. I ſuppoſe in this caſe, that the blood and nervous juyce grow too ſour, from the ſalt carried forth, and ſuffering a Flux, and therefore that they are ſomewhat looſned in their mixture, and fuſed ſo much into ſeroſity, as to be made fit for it. For it is to be obſerved, that all Liquids, though more thick and mucilaginous, if they be kept to a ſourneſs, preſently become for the moſt part watry and limpid: alſo the flowing down of the Urine is ſometimes ſeen to ariſe from ſuch a diſpoſition of the blood and humors: for that the Urine ſo copiouſly excreted, is like Vinegar in taſte; and theſe kind of diſtempers are uſually cured, chiefly by Chalybeates, and not by binding and thickning things.

But as to what reſpects the Colour, the Urine of ſound people may be the ſquare or rule, to which all the reſt of the ſick may be referred; for as the colour of ſound peoples is Citron, the Urine of the ſick is paler than Citron, and ſo either watry, or white, or higher coloured than it; whoſe cheif kinds are, flame-colour, yellow, red, green, and black. I ſhall run through every one of theſe briefly, and endeavour to weigh them together, by what cauſes all the alterations may be made, and what diſtempers, or proviſions of diſeaſes they are wont to make known.

The Urine is watry or limpid, when by reaſon of the indigeſtion of the Ventricle, the ſaline and ſulphureous particles of things eaten, are not rightly ſubjugated, nor being ſmally broken, are made ſo volatile, that being diſſolved in the Serum, they may impart to it a tincture, which it may carry with it, through the ſeveral turnings and windings of its paſſage: For the Latex or juyce to be changed into Urine, becauſe it is forced through very ſecret paſſages, and narrow, as it were by a certain diſtillation; therefore it is wholly deprived of the colour and conſiſtency, which it had from the taken Liquids, and imbibes almoſt nothing, but the volatile part, from the Chyme, whoſe Vehicle it is. Wherefore, if by reaſon of the great crudity, the Salt, Sulphur, and other contents are not firſt made volatile in the Viſcera, nor afterwards diſſolved in the Veſſels, that they may make their paſſage together with the ſerous juyce; it being at laſt ſtripped almoſt of all, is ſent out like clear water. That ſuch Urines do want the active principles, it is a ſign, becauſe they are kept a long time from putrefaction: This ſort of Urine denotes in Virgins, for the moſt part, the Green-ſickneſs, in moſt the Cachexy or Dropſie; in all it is a note of indigeſtion and crudity. Sometimes in thoſe obnoxious to the Stone, it foretels the approach of the fit, *viz.* whilſt the Serum is coagulated by the ſtony juyce in the Reins, its diſſolutions and contents are congealed into a tartareous matter, only a watry juyce or Latex ſtaying behind. Thoſe who for ſome time make a thin and watry Urine, what ever ſickneſs they are obnoxious to, have often adjoyned to it a difficulty of breathing, and ſhortneſs thereof after motion, and diſtention about the region of the Ventricle, and as it were a ſwelling up after eating. The reaſon of the former wholly depends on the defect of ſpirits in the blood, becauſe its liquor is not fully imbued with active principles (of Spirit, Sulphur, and Salt) rightly exalted; therefore it is not ſufficiently kindled by the ferment of the heart, whereby the whole may preſently leap forth, and break as it were into a flame: but that hardly fermenting, and being apt to ſtagnate in the heart, and for the moſt part to reſide there, burdens it grievouſly: wherefore if the blood ſo diſpoſed, is urged more than it is wont, by a more quick motion, into the boſom of the Heart, becauſe not being rarified of its own accord, it may preſently go wholly forth, therefore there is need of great endeavour of the Lungs, and a more quick or frequent agitation, whereby it may be carried forth. Therefore watry Urines ſignifie this kind of Crudity in the blood; becauſe, for as much as they receive no tincture almoſt from the Salt and Sulphur, it is a ſign that the Particles are little diſſolved in the maſs of blood, or are rendred volatile. As to what appertains to the inflation of the Ventricle (of which alſo limpid or clear Urines are the effect and ſign) I ſay, becauſe of a defect of due Fermentation, the Chyle goes not into a volatile Cream, but (like bread not fermented) into a ſad and heavy maſs, which indeed is ſlowly, and not without a reſidence of viſcous Phlegm, carried out of the ſtomach: its reliques being impacted in the folds and Membranes of the Ventricle, obſtruct all the Pores and paſſages, that nothing may vapour forth, nor that the thin and ſpirituous part may be conveyed (as it ought to be) by the ſecret paſſages, to the blood: hence flatulencies are begotten, which continually diſtend the Ventricle, and blow it up beyond its due bulk: alſo when thoſe Feculencies are left a long time in the ſtomach, they abound in a fixed Salt, and degenerate now into an acid, now into a vitriolick matter, or of ſome other nature; from whence Heart-aches, deſire of abſurd things, oftentimes Heat with cruel thirſt, and ſometimes Vomiting ariſe: ſome of which though they argue a very ſharp heat to lye hid within, yet by reaſon of the want of concoction, ſuch diſtempers often render the Urine crude and watry. We have treated thus largely of a limpid or clear Urine, becauſe from hence the reaſons of the reſt (which as to colour and conſiſtency are pale and thin in healthful perſons) may be drawn. For from the Salt and Sulphur, more or leſs diſſolved and boiled in the Serum, the appearances of a pale and ſtraw-coloured Urine, and of other colours, under a Citron colour, are excited; and by the like means, which was ſaid of the watry, they may be unfolded.

There remains another certain kind of Urine, more pale than the Citron Colour, not thin but thick and cloudy, and of whitiſh colour; it appears by common obſervation, that children do often make ſuch water, when they are troubled with the Worms: The reaſon of which ſeems, becauſe the matter whereof the worms are made, is a certain viſcous Phlegm, heaped up in the Viſcera, by reaſon of the indigeſtion of the Chyle, and a defect of making or generating Spirits, which matter at firſt tranſmits no tincture to the Urine, becauſe of its fixity, the ſame afterwards putrifying is exalted, and is in ſome manner volatilized; and then partly by heat and ſpirit, is formed into worms, and partly being confuſed with the paſſing Chyle, and carried into the veſſels, when 'tis made unfit for nouriſhment, it is ſeparated with the Serum from the blood, and being mixed with the Urine, gives it that white colour. Sometimes alſo in Fevers, eſpecially of children, The Urine is whitiſh: the reaſon of which is, becauſe the ſupplement of the nutritious juyce being poured from the Chyle to the maſs of blood, is not rightly aſſimilated, degenerater into an excrementitious humor: A portion of which being incocted in the Serum, imparts to it the the thick conſiſtence and milky colour: otherwiſe than in the Fevers of thoſe of riper years, where when the heat is ſtronger, the ſame degenerate juyce impreſſes on the Serum a red colour. Alſo the Urine is whitiſh in the flowing of the Whites, the Gonorrhea, Ulcers of the Reins and Bladder, and of the Urinary paſſages, by reaſon of the confuſion or mingling of the filthy matter, or the corrupted ſeed: howeves it be, that the colour of the Urine be white, it is produced from its contents, which at laſt putting down its ſettlement to the bottom, the liquor for the moſt part becomes of a paliſh and yellowiſh colour; even as it may be perceived by the making of the Milk of Sulphur, where the milky ſubſtance ſinking down to the bottom, the overſwimming liquor is of a Citron colour.

Urines whoſe colour is deeper than Citron, owe their appearance, not only to the Salt and Sulphur diſſolved more than uſual, but in ſome ſort to the more thick contents in the liquor. The more plentiful diſſolution of the Salt and the Sulphur, is chiefly performed in the veſſels, in the maſs it ſelf of the blood, and from thence the Tincture is impreſſed on the ſerous Juyce: But this happens to be done for the moſt part, after a double manner, *viz.* either by reaſon of the feveriſh fervour, for as much as the blood boiling in the veſſels, and being more kindled in the Heart, is very much looſned in its mixture, and ſo copiouſly fixes on the Serum the particles of Salt and Sulphur, waſted as it were by the boiling: Or without a Fever, when theſe kind of ſulphureous and ſaline little bodies, wont to be ſent forth at other ſinks, are reſtrained; and ſo being by degrees heaped up in the blood, are poured into Serum. Of this alſo there are two cheif cauſes or means; for either the excrements of the blood, which cheifly participate of aduſt Sulphur, and that ought to be ſent away by Choler-carrying veſſels, are retained, and ſo they impreſs, being ſuffuſed on the ſerous humor, a tincture of yellowneſs: or elſe the Effluvia's, which are chiefly of a Saline nature, and ought to be evaporated by inſenſible tranſpiration, are reſtrained, and from thoſe the urine is filled with a lixivial tincture. The Urines of the former kind are proper to people that have the Jaundice; but thoſe of this latter are familiar to the Scurvy: for in the Scurvy the ſaline particles of the blood depart from volatilization, and get a Flux: wherefore, by reaſon of their fixity, they will not evaporate, and ſo being more fully heaped together in the blood, they more and more pervert its Craſis, and very much impregnate the ſerous humor with a ſaltneſs. The contents which heighten the colour of the urine, are of a twofold kind to wit, either aduſt recrements, remaining after the deflagration of the blood, or particles of the nutritious juyce, degenerated into an extraneous matter: Concerning which we ſhall ſpeak hereafter in their proper place. It now remains that we deſcribe particularly the ſeveral colours of urine more intenſe or deep than Citron colour.

1. The firſt is a flame-coloured Urine, which ſhines with a brightneſs like the Spirit of Nitre: and this is very often ſeen in an intermitting Tertian Fever; this colour ariſes from a portion of the thinner yellow Bile, mixed with the Serum, whilſt it is in motion: for that in this Fever there is a ſharp and hot intemperature of the blood, which burns and ſcorches all the humors, and ſo plentifully begets Choler. But although this, for the moſt part, is ſeparated from the maſs of blood by the Bilary veſſels and paſſages; yet when it abounds in the veſſels, a part of it, or (which is the ſame thing) ſome burnt and aduſt particles of the blood and humors being boiled in the ſerous water, impart to it an high or deep yellowneſs. This urine is thin and ſhining, for that there is in this diſeaſe almoſt a continual breathing forth, thatthruſts out the recrements of the nutritious Juyce, and all the thicker parts of the Serum towards the circumference of the body.

2. The Saffron-coloured Urine, and which dyes Linen with the ſame colour, undoubtedly is a ſign of the Jaundice: it is tinged after this manner by the yellow Bile or Choler, or by the Salt and Sulphur burnt and plentifully mixt with the Serum: for the yellow Bile is neceſſarily begot from the yoked heat and motion of the blood; but for this the Gall bag is deſigned by Nature, for the ſeparating it from the maſs of the blood, its paſſages being rooted in the Liver: But if ſuch a ſeparation be any ways hindred, that humors flowing back in the blood, and copiouſly heaped together, infects the skin with its yellowneſs, the blood, and eſpecially the ſerous Latex. The Saffron-coloured Urine differs from the flame-coloured, becauſe in this only a certain portion of the more thin Bile is poured into the Urine, but in that the more thick part, and much more plenty: beſides, in the yellow Bile the Sulphur, with the Salt, being joyned and long circulated, is fully diſſolved by it, that it becomes like paint, imparting to every ſubject a Saffron-coloured tincture; as when common Sulphur and Oyl of Tartar are mixed together. But what things cauſe a redneſs Urins, without the reſtagnation of this Bile,

happen

happen after the ſame manner as in the Lye of Aſhes: where the particles of the Sulphur, without any previous diſpoſition from the ſaline, are forthwith put down with them in the Liquor.

3. It remains that we ſpeak next of red Urines, which are of a divers habit, neither do they always depend on the ſame cauſes, nor plainly denote the ſame kind of diſtempers; we ſhall briefly run through the cheif differences and proper ſignifications of them. Firſt, the liquor of the urine is either red of it ſelf, and remains after the ſame manner, nor is the colour altered by the ſetling or ſinking down of any of the parts: or ſecondly, the redneſs of the urine chiefly owes its colour to the Contents, which being ſetled to the bottom, the liquor grows yellow, or is leſs red. The diſtempers that theſe kind of urines are wont to ſhew, are chiefly Fevers, and a confirmed Scurvy, and Conſumption. We ſhall now conſider the reaſons of each.

1. When the Urine that is made red ſo remains, it is firſt of a mean conſiſtency, and ſomewhat clear, and then it owes its colour to the Salt and Sulphur, being burnt more than uſual, and ſo boiled more copiouſly in the Serum: or ſecondly, ſuch an urine is red, and alſo troubled and cloudy: but this, beſides the contents of Salt and Sulphur, has boiled in it ſome earthy particles alſo, which indeed being impacted in the Pores and paſſages of the ſerous Latex, do not deſcend: becauſe the liquor of the urine is deſtitute of convenient ſpirits, which may ſegregate all heterogeneous things, and drive them to the bottom, as it is wont to happen uſually in dead drink, or Beer growing ſour by reaſon of Thunder; where the liquor is infected with a troubled Feces, and by reaſon of the defect of ſpirits, will not grow clear; wherefore this kind of urine is a very bad ſign in Fevers becauſe it ſhews ſuch a confuſion in the blood of aduſt and to be ſeparated matter, ſuch as the vital ſpirits are not able to maſter by taming and ſubjugating it.

2. Sometimes the Urine is made red, by reaſon of its contents; which ſetling in the bottom, the liquor becomes of another colour: but theſe contents, as before we hinted are twofold, *viz.* now thin, which are the remaining matter, or aduſt recrements after the burning forth of the blood; now more thick, to wit, the degenerate particles of the nutrious Juyce; both theſe being torrified, and ſeparated from the burning blood, are partly thruſt forth by Sweat, and partly mixed with the ſerous Latex, thicken its conſiſtence, and heighten its colour, *viz.* ſo long as theſe kind of contents are included in the Pores and Paſſages of the liquor, they are ſuſtained, the colour of the urine appears more deep, and the conſiſtency thicker: but theſe being precipitated to the bottom, both the redneſs and thickneſs of the liquor are leſſened. The reaſon of this ſhall be given anon, where we ſhall ſpeak of the Cauſes of the Colours, and alſo of the Clearneſs and Cloudineſs of Urines: we ſhall now inquire, what is the reaſon of the difference, that red urines are wont to be made both in Fevers, and alſo in the Scurvy, Conſumption, and perhaps in ſeverall other diſtempers.

1. In Fevers, the liquor of the Urine is filled with redneſs, becauſe of the more plentiful diſſolution of the Salt and Sulphur, and their particles copiouſly boiled in the Serum; for whilſt the blood and humors grow hot, from the feveriſh cauſe, by reaſon of the heat being more fully inkinded, the ſaline and ſulphureous little bodies being burnt and torrified, are more diſſolved; and being boiled in the ſerous Juyce, impart to it a deeper tincture: Even as if the Lye of Aſhes be boiled over the fire, it grows more red, than if it were only only made by infuſion. Alſo in Fevers, the contents of the urine moſt often increaſe its colour, *viz.* by reaſon of the intemperance and deflagration of the blood, both the degenerate particles of the nouriſhing Juyce, and alſo other matter (as it were the Aſhes remaining of the burning of the blood) are burnt together, as it were into a reddiſh Calx; which being included in the Pores of the urine, renders its colour deep, and afterwards ſinking down, makes a ſediment like red Oker.

2. In a long Scurvy, the liquor of the Urine grows ſometimes ſo highly red, that it cannot be greater in a burning Fever: if ſuch urine be evaporated, or expoſed to diſtillation, it will ſhew great plenty of Salt, with a muddy Feces or dreges: wherefore it ſeems to be manifeſted, that this deep redneſs doth cheifly ariſe from the Salt, (as we have already hinted) by this Experiment; becauſe in Scorbutick people the ſaline particles, which ought to be made volatile, and ſo conſtantly exhaled by tranſpiration, become fixed, and being hindred form a flux, are heaped together more plentifully in the diſtempered body. The Salt remaining within, is variouſly coagulated with Sulphur and Earth, and then is continually diſſolved: and from this diverſe coagulation and diſſolution, the to be admired Symptoms of this Diſeaſe are cauſed, Alſo from the ſaline little bodies plentifully diſſolved with Tartarous feculencies, and diluted with the Serum, urines are filled with an high redneſs; to which moſt often happen in this inveterate diſeaſe vices of the Liver and Gall; for when theſe inwards, being either obſtructed or other ways depraved, cannot perform their tasks, for the ſeparting the aduſt particles of the blood, they being more fully heaped up in the blood, are diſſolved in the ſerous Juyce, and infect it yet with a more lixivial tincture. And if the aduſt particles of the Sulphur do excel the reſt of the fixed and ſcorbutick Salt, the yellow Jaundice happens together with the Scurvy, and the urine fixes to Linen a Saffrony tincture. But if they be leſs than they, and that the ſaline particles excel, the Scorbutick diſtemper only is produced, in which the urine in intenſly red yet does not dye the Linen. I am perſwaded that it is thus; becauſe, when I have opened the dead carcaſſes of many dead of the Scurvy, in whom there was a red urine, I obſerved that the Liver or Gall was in fault: In ſome the Liver was wholly without blood, and dry like a Cows Udder; in others the bag of the Gall was empty, and nothing in it; in others it wa, beſet with little ſtones; in others it was filled with filth, not bitter; in all theſe Inwards were ſo diſtempred, that the ſecretion of the Bile was hindred.

3. By reaſon of this kind of diſſolution of the Salt, Urines ſometimes grow red in Arthritick diſeaſes: for beſides the Gout (in which ſuch Urine is often made) I have obſerved in ſome a painful diſtemper, and as it were like a Fever, cauſed, with a very high-coloured Urine; they had wandring pains, now in this place, now in that, grievouſly tormenting, that the ſick were ſcarce able to ſtand, or to ſtir their limbs: they were obnoxious to wakings and frequent ſweats; they were alſo troubled much with thirſt, and heat of their mouth: and they had a Urine highly red, with a plentiful red ſediment. In the mean time it did not appear, either by the Pulſe, languiſhing of the Spirits, or Head-aches, that the blood grew exceſſively hot, or that they had a Fever. Wherefore I ſuppoſe that this kind of diſtemper doth chiefly conſiſt in the nervous ſtock, and depends on the exorbitances of the ſaline Principle, rather than the ſulphureous.

4. Alſo in the confirmed Phthiſis or Conſumption, eſpecially if an Hectick Fever be joyned with it, there is a red Urine; the reaſon of which is, if at any time an Ulcer is excited in the Lungs, the putrid filth from thence being mingled with the blood ſliding by, cauſes in it almoſt a continual effervеſcency, whereby the ſulphureous and ſaline particles being more plentifully diſſolved and boiled in the Serum, affect its liquor with redneſs: beſides, by reaſon of the blood being defiled after this manner, the nouriſhing Juyce degenerates almoſt wholly into putrefaction, by whoſe recrements the Urine being filled, grows more red, and is very much ſtuffed with contents: The ſign or note of this is, that the ſick for the moſt part grow hot after eating, and that they are troubled with an heat through their whole body, followed with a nightly ſweat; beſides, their Urines yield a thick and copious ſediment, to wit, when the nouriſhing Juyce, being mixed with the blood, is not aſſimilated, it ſtirs up in it a fervour, and being degenerate into an extraneous matter, exhales partly by ſweat through the Pores of the skin, and partly being tranſmitted to the Urine, very much heightens its colour and conſiſtency.

Thus far of a red Urine, whoſe ſeveral ſpecies, but now related, have more degrees of intention and remiſſion, accordingly as the cauſes, altering the colour and conſiſtence in them, are either weaker or ſtronger.

4. As to what belongs to a green and black Urine, I confeſs I have never ſeen thoſe kind of deep colours (exactly like thoſe of Leeks and Ink) in any Urine: but I imagine I may have ſeen the appearance of a greeniſh colour from a more deep yellow, and of a blackiſh Urine from the ſame with a cloudy and ſomewhat a dark mixture, and from thence called by Authors a green and black Urine. But thoſe Urines, coloured after that manner, are eſteemed either ſigns of the Jaundice, or of being diſtempered with ſome virulency of the blood, if they continue ſo conſtantly for ſome time: or ſuch Urines, as occaſion offers, are variouſly changed, and are now of this or that, and preſently of another colour. So I have known Hypochondriacks wont to make ſuch Urines, as it were critically for ſome time, and then afterwards to render them like ſound men. As to the firſt, when the Jaundice is very great upon them, that the aduſt portions of Sulphur and Salt remain a long time in the maſs of blood, they acquire by a long incoction a fulneſs of the yellow colour, at firſt green, and afterwards black, and impart the ſame to the Serum: For if the yellow Bile, being taken out of the bag of the Gall, and put into a Cucurbit, be expoſed to the gentle heat of a Bath, the ſame in a ſhort time will grow green, and afterwards appear like the blackeſt Ink: wherefore in the black Jaundice, which is only the yellow carried forth into a worſe ſtate, by its long ſtay or continuance, there is nothing more uſual than to make black Urine. Beſides, theſe kind of Urines ſometimes appear in a malignant Fever, and in the Plague, alſo often from drinking of poyſon, and in this caſe it is for the moſt part a ſign of death, becauſe it argues the blood greatly corrupted, and the ſpirits profligated, and the bond of the mixture looſned, as it were the deadly or mortified diſtemper: even as were ſome part of our body, being diſtempered with an Ulcer, is afterward taken with a Gangrene or mortification, forthwith the flowing corrupt matter, which was at firſt white, wateriſh, or yellow, becomes black. Wherefore in the forementioned diſtempers, when the Urine grows black, the Serum and the blood being wholly vitiated, the skin alſo is dyed outwardly with ſuch a colour. As to what belongs to Urines periodically tinctured with a greeniſh colour, and eſpecially with black (which happen often to Hypochondriacks) it is moſt likely, that ſuch ariſe from the melancholick Feculencies laid up in the Spleen, and from thence, by reaſon of its congeſtion, too much flowing forth ſometimes, and confuſed with the blood: for ſuch a matter, being often poured into the Ventricle in ſome men, ſtirs up black Vomitings; alſo in others, the ſame being ſupp'd up from the blood paſſing through, may impart ſuffuſions of the ſame colours to the ſerous Juyce.

So much for the Colours of Urines, of which the more pale ariſe from too much Crudity, almoſt all the high-coloured, either from the Salt and Sulphur plentifully diſſolved, and ſometimes from the aduſt recrements throughly boiled in the Serum, or from the more thick contents of the Urine; whether they be the Calx and remaining part of the aliment, degenerated in the concoction, or the waſting or melting of the pining body, or ſome part of it evilly diſtempered: what hath been ſaid may be better underſtood, if the means, whereby theſe kind of diſſolved things or contents are able variouſly to change the colour of the Urine, be unfolded.

The cauſes of the diverſity of appearances of colours, and their variouſly changing, as alſo of the cloudineſs and clearneſs in Urines, (as in all other Liquors) depend only on the various incidency and emerſion of the beams of light, as is hinted in another place, in the Tract of Fermentation: For if the ſubſtance of the liquor be rare and thin, with open Pores and paſſages, that the beams of light may eaſily paſs through,

through, it is ſhining and clear like fountain water: but if the Pores of the liquor be filled with contents, or little bodies ſwimming in it, ſo that the luminous beams are broken in their paſſage, but ſo that at length they may ſhew themſelves, according to thoſe various manners of refraction and emiſſion, there will appear a Citron, a Saffron, or red colour in a yet clear liquor. If that, in the little ſpaces of the Porces yet more obſtructed, the light cannot paſs through, there is a darkneſs induced: but then if the immerſed beams be a little or nothing reflected, the liquor will appear of a brown or dark colour; but if they are beaten back, according to the diverſe manner of reflection, a white, aſhy, or ſome other kind of appearance, is induced. From this being ſuppoſed, according as the liquor of the Urine, ſometimes almoſt wholly deprived of Salt and Sulphur, and other things diſſolved, eaſily admits of light, ſometimes either very much ſtuffed, or elſe moderately with theſe kind of contents, either diſtorts the beams falling on them in their paſſage, or wholly imbibes them, or laſtly beats them back; it were eaſie to explicate all the Phænomena or appearances of colours and their conſiſtence.

It often happens, that the colour of the ſame Urine is variouſly changed: for what is made red, being expoſed to the air, becomes white, or of a dark colour, and then after a long time of Citron colour: the reaſon of which is this, if I am not deceived, this kind of Urine, when it is made, is red, becauſe the Pores of the Liquor are very full of contents; yet ſo long as they are dilated with heat, they tranſmit the rays of light, (although variouſly diſtorted) that they may at length ſhew themſelves or appear; but this Urine is no ſooner expoſed to the cold, but that the Pores being ſtraitned, the ſite and poſition of the parts is changed in the contents, and by that means the paſſage of the beams of light is hindred: wherefore the liquor preſently becomes cloudy, and according as thoſe beams are reflected after this or that manner, a white, or brown, or ſome other kind of colour is induced: but at length the contents falling down towards the bottom with their weight, the Pores being freed, tranſmit again the rays of light, and do not diſtort them; wherefore a clear or a Citron colour appears.

From theſe things which have been ſpoken concerning the Colours of Urins, may appear what is the cauſe of the various conſiſtence of Urines. For the particles of Salt and Sulphur, of the aduſt matter, or nutritious Juyce, depraved in the ſimilating, are more or leſs boiled in the Serum, Urines alſo get their more thin or thick conſiſtency. It remains next that we ſpeak more clearly of the Contents in preternatural Urines, whereof we have often made mention.

CHAP. V.

Of the Contents in the Urines of ſick People.

WE ſuppoſe the Contents in the Urines of ſick people to be twofold, *viz.* either univerſal, which proceed from the maſs of Blood, and of the nervous Liquor, and reſpect the habit of the whole Body; or particular, which are the layings aſide or excrements of one bowel, or part ill affected, of which we ſhall ſpeak anon. Thoſe of the former kind, which come away from the whole, are either natural, *viz.* Filaments or ſmall threads conſtituting the Hypoſtaſis or ſettlement, as in ſound Urins; or preternatural, which chiefly are particles of the nutritious humor degenerate from aſſimilation, and conſtitute to more thick bodies of the ſediment in Urines; and laſtly to theſe, (if there be a feveriſh intemperance) the aduſt matter of the blood after deflagration, and diluted in the ſerous Juyce, is added, and increaſes the bulk of the Contents.

But theſe Contents, both natural and preternatural, of Urines, repreſent themſelves after a various manner, as the blood more or leſs unduly grows hot, alſo as the aliments in the bowels and veſſels are variouſly concocted, and either the ſuperfluities or corruptions of the Chyme, thence made, are waſhed away with the Serum: for if the nouriſhable humor tranſmitted to blood, is not at all perverted, but a great portion of it, laid upon the ſolid parts, is changed into nouriſhment, ſome parts of this alſo rightly made, being mixed with the Serum, impreſs yet ſome marks of an Hypoſtaſis in Urines: Alſo from the aduſt or degenerate matter, a preternatural ſediment is framed, yet little and thin, neither doth it wholly blot out the appearances of this natural. Wherefore in the begininning and declination of a Fever, ſometimes alſo in a Conſumption, or a Cachexy, an Hypoſtaſis, though not ſo perfect, is perceived. If that the greater portion of the ſame Chyme, growing hot with the blood, by reaſon of the immoderate heat, is perverted into an heterogene matter, which afterward is ſent away with the Serum, as hurtful and unprofitable, preſently an obſcure and imperfect Hypoſtaſis appears; and beſides it, very many contents are ſeen in the Urines, which heighten their colour and conſiſtency. Such an Urine, which contains an Hypoſtaſis, though imperfect, together with other things of the ſame kind diſſolved in it, if it be kept in a warm place, the Hypoſtaſis will be perceived alone; but the reſt of the contents, comprehend in the pores of the Urine, dilated by the heat, are made wholly inconſpicuous or not to be ſeen: yet afterwards the little ſpaces of the Pores being ſtraitned by cold, the ſame contents are precipitated,

and

and by that means they render the ſite and poſition changed, and the Urine troubled and cloudy, and blot out the appearance of the Hypoſtaſis. Theſe kind of Urines in the better ſtate of Fevers in a Catarrh, Cough, difficulty of perſpiration, fulneſs of humors, and in the more light Dyſcraſies are wont to be made.

But if in the more grievous ſtate of ſickneſs the Concoction be wholly vitiated, and the whole nutritious Juyce changed into a putrefaction, theſe kind of contents alſo may be perceived in the Urine without an Hypoſtaſis, and ſignifies variouſly in diſeaſes, after their various ways of being precipitated, and ſinking down, and conſtituting a diverſe kind of ſediment; to wit, as the ſeparation of the parts ſucceed ſoon or late, or not at all; and as the matter falling down ſhall be little or much, or alſo of a white, red, or dark colour. I will briefly run through what is moſt notable and worthy obſervation concerning this thing.

1. This kind of Urine being full of contents, is not ſometimes at all precipitated, (unleſs the ſubſtance of the liquor be diſſolved by putrefaction a long time after) but remains a long while troubled and ſomewhat cloudy, with little bodies ſwimming through the whole. The reaſon of this is, either becauſe theſe contents are too much incocted in the Serum, ſo that the ſpirits implanted therein, cannot ſeparate the pure from the impure, the thick from the thin; as may be perceived in brewing Beer, if that the Mault be too much boiled, the liquor ſhall never grow clear: or elſe the Urine remains troubled, becauſe it is wholly deſtitute of ſpirits, which may compel the parts of the liquor into the motion of Fermentation; as it uſually comes to paſs in Beer growing ſour by reaſon of Thunder, or of immoderate heat, and being infected with a troubled Feces or Lee, will ſcarce ever be rightly made clear again. This kind of Urine is perceived for the moſt part in very dangerous Fevers, and ſometimes in a deſperate Cachexy, and always portends evil.

2. Sometimes it happens, that the Urine is ſo full of contents, that it begins to be troubled whilſt it is yet warm. I have often obſerved it, after this manner, in a ſlow Fever, whoſe heat was gentle and more remiſs, to wit, in which the particles of the nutritious craſſament or ſubſtance are depraved, but being a little ſubdued by heat, or boiled in the Serum, they eaſily fall out of its pores: as when common Sulphur is boiled in Lye, if that before it be perfectly diſſolved, it be taken from the fire, the liquor at firſt clear and red, by reaſon of the quick precipitation of the diſſolved matter, becomes preſently troubled, dark, and of a ſomewhat whitiſh colour.

3. But what moſt uſually comes to paſs, that this ſort of Urine, big with contents, as long as it is hot, and ſome time after, ſeems clear and perſpicuous, when it grows cold, is wont to be troubled, and as if ſome Runnet were infuſed to be precipitated according to all its parts; yet the ſame, if held near the fire, or in warm water for a little ſpace, ſhall grow clear again. The reaſon of this is already fully unfolded, where we ſpake of the Cauſes of Cloudineſs and of Clearneſs.

4. After that the Urine being expoſed to the cold, is precipitated in this manner, it may be obſerved by what means its contents deſcend to the bottom, for ſometimes they ſettle in ſhort a time: and if the liquor grows clear in the ſpace of two or three hours, it is a ſign that the liquor of the Urine is not too thick, nor very much filled with Salt and Sulphur: wherefore in the beginning or declination of Fevers, when the heat is ſlack, ſuch an Urine is moſt often made: ſometimes ſuch a ſettlement follows not but in the ſpace of many days; the reaſon of which is, becauſe the conſiſtence of the liquor is thicker than it ſhould be, therefore the contents or diſſolved things are not ſo eaſily let go from its embrace, that they may fall down to the bottom by their weight. Theſe kind of Urines are wont to be made in the ſtate or height of Fevers, and moſt often precede an evil Criſis.

5. Of no leſs a diverſs kind are the ſediments which fall to the bottom. That I may paſs over in this place the filthy matter, and blood, ſand, gravel, and the like, depoſited from ſome parts, I ſhall mention thoſe which are the products of the whole body, and they for the moſt part are either white or brown, or red like Oker: If you ſtrain Urine, when it hath ſtood long, through brown paper, you may collect theſe contents. I have often ſeen a whiteneſs like Chalk, and ſometimes red like Bole Armene, without doubt there is the ſame matter of all, to wit, the recrements of the deflagrated blood, and of the nutritious juyce depraved in the aſſimilating: which, as they are burnt by heat in our body, and diverſly perverted, appear alſo in the Urine under a various colour and form; even as Antimony mixed with Nitre, as it is more or leſs calcined exhibits a Calx, now red, now Saffron colour, now yellow, now brown: The like reaſon is (as it ſeems) of the ſediments of Urines, which are as it were the Calx of the ſulphureous and earthy matter burnt forth by the fire of the Fever in the Viſcera and Veſſels.

6. Beſides theſe kinds of Contents, which happen in the Urines of ſick people, I have often obſerved, that after the Urine had ſtood a long while, ſomething was affixed to the ſides of the glaſs like ſand, and indeed in divers figures; for now theſe little bodies like ſand grow together with a ſharp and unequal ſuperficies, now with ridges like the Cryſtals of Nitre, and ſome ſhine and are pellucid like Ice. I have ſeen theſe kind of Cryſtals fixed to the Urinal, ſometimes in the Urines of thoſe troubled with a Dyſentery, alſo in thoſe troubled with pertinacious wakings. Sometimes in Urines, when they have ſtood long, a certain Cream will ſwim on the top, as when Tartar is boiled in water: this kind of whitiſh cruſt growing together in the ſuperficies of the Urine, is commonly thought to be fat and fattiſh things, and taken for the melting of the ſolid parts: wherefore ſuch as are wont to make ſuch an Urine, are preſently pronounced to be conſumptive, and in a deſperate condition: But indeed that is only a ſaline concretion

which,

which if put into the fire, will not melt, but grows hard into a cruſty ſubſtance. Yea both this and the other concreſcences of Urines are as it were the Tartar brought forth in them by a certain Coagulation: But ſuch a concretion depends altogether on the particles of the fluid or acetous Salt, combined with others of the fixed or Alcaliſate Salt: For in every ſubject where there is a commixtion of the Salts of either kind, Cryſtallizations and Coagulations of a diverſe manner are cauſed, either ſpontaneously by Nature, or may be procured by artificial ſeparation: wherefore this kind of Urine, on which this Cream ſwims, or that Cryſtals gather in the ſides of the Veſſels, indicates the blood to be departed, from its ſweet and Balſamick nature (ſuch as depends of the volatile Salt) into an acid and corroſive, by reaſon of the flux and fixity of the ſaline Principle. Such an Urine, if it be evaporated, leaves in the bottom of the Veſſel great Plenty of Salt: the diſtempers wherein it is uſually found (as I have often obſerved) are ſpitting of blood, Atrophy, or general waſting, and the Hypochondriack diſpoſition.

In the Urines of ſick people it is worth obſervation, whether they dye the Urinal or not? For ſometimes in Fevers the Urine is no ſooner put into the Glaſs, but preſently it darkens its ſides with a whitiſh cloud, and again at another time this does not happen: I ſuppoſe that the Glaſs is dyed, when the liquor of the Urine is fuller of diſſolved Sulphur, than its pores can contain within themſelves; as may be preceived in Lye, wherein common Sulphur or Antimony is boiled: Alſo every Urine, if it ſtand in the Glaſs till it putrifie, will infect its ſides with a cruſt or cloud, ſometimes whitiſh, ſometimes reddiſh, ſometimes of another colour: for the frame of the liquor being looſned by putrefaction, the particles of the Sulphur being looſned from the bond of mixture ſtick to the Glaſs: But in the Urines of ſick people ſometimes this preſently follows, becauſe the Sulphur is more copiouſly diſſolved than can be included in its pores.

As to what reſpects the particular Contents of Urines, they indeed are manifold, and may come from many parts and places: yet they moſt often depend on diſeaſes implanted about the Reins, Bladder, and Urinary paſſages: ſometimes it happens by reaſon of an Impoſthume in the Liver, Spleen, Lungs or other inward; or by reaſon of preternatural humours heaped up in thoſe places, and flowing out with their fulneſs, an extraneous matter is tranſmitted into the maſs of blood, and thence into the ſerous Juyce: but this happens more rarely, becauſe an impoſthume being broken within, for the moſt part pours out its matter into the cavities of the Viſcera, from which there is no paſſage open into the Urinary paſſages: beſides the maſs of blood flowing with impurities, does not preſently endeavour to ſend them forth by Urine, but oftener by ſweat, ſpitting, breaking out of Wheals, Tumors, or by other ways of excretion. Wherefore it appears by common obſervation, that the other contents of Urines (that which we have above cited) are chiefly ſent from the Reins and their dependences; the chief of which are ſand, ſtones, blood, matter, bits of fleſh, skins, branny or mealy ſediments, which for the moſt part ſignifie either the ſtony or an ulcerous diſtemper, or both together, planted beyond the emulgent Veſſels.

It is an uſual thing for ſome to void with their water, gravel or ſmall ſand of a red colour in great quantity; ſome of theſe are obnoxious to the ſtone in the Reins, and are frequently tormented with Nephritick fits: I have alſo known others without pain, or other grievous Symptom, for a long time to make a ſandy water. All Urines whatſoever, if they ſtand for ſome time in a leaded or earthy glazed veſſel, affix this kind of red ſand to the ſides and bottom of the Pot, to wit, the volatile Salt of the Urine is coagulated with the fixed Salt of the Metal: ſo when Salt Armoniac being mixed with the filings of Steel, Sea-Salt, or Vitriol is ſublimated, the elevated flours grow notable red: wherefore it ſeems that theſe kind of little ſands are begot in the Reins, for that the Salt of the Urine is coagulated with the Tartarous feculencies laid up about the windings of the Reins, from whence the ſandy matter is made, which is preſently waſhed away by the ſerous Juyce paſſing through: Therefore the gravel that is ſo frequently made are no ſmall parts or fragments of a greater ſtone, (as is commonly thought) but extemporary products of the blood and Serum waſhing the winding paſſages of the Reins.

By what means little ſtones are produced in the Bladder or Reins, is not to be fully diſcourſed in this place: But without doubt it is done rather by Coagulation than Exſiccation or Excalefaction, by drying or heating, I have obſerved ſome ſick of the Stone in the Bladder, who after they have made water, were wont to void with great ſtriving and pain a thick and viſcous Juyce, which preſently hardned into a ſcaly matter: the ſmell of this was like Lye, and of ſuch a conſiſtence as Lye evaporated to a thickneſs, the liquor of which being made thick, preſently ſtiffens into a ſaline hardneſs. Leſſer ſtones ſometimes paſs through the Urinary paſſages, and are carried out: the greater remain unmoved in their Cells. The places wherein they are uſually begotten are the narrow winding boſoms of the Reins, from thence the ſmaller ſlide into the Bladder, and if not excerned, they grow into great ſtones. I once ſaw many great ſtones ſhut up as it were in a Cheſt about the ſides of the Bladder between its Membranes; theſe without doubt being ſent from the Reins while ſmaller remained in the paſſages of the Ureters, creeping between the Coats of the Bladder, and there by degrees did increaſe in bulk. A Matron ſo diſtempered long before her death, caſt out of the Urinary paſſage a Membrane thick and broad, full of ſandy matter, which (as appeared after her body was opened) was part of the interior Tunick of the Bladder worn and broken by the ſtones there included.

It is ordinary for Nephritick people, or ſuch as are troubled with the Stone, frequently to void blood or matter with their Urine: for from a greater ſtone, and endued with ſharpneſs, the fleſh of the Reins is eaſily worn, and the mouths of the Veſſels opened, whereby blood flowing out, tinges the Urine; and when a ſolution of unity is cauſed in this manner in the Reins, an Ulcer moſt commonly follows, whereby matter and filthy ſtuff are poured out with the ſerous water, and conſtitute a plentiful and ſtinking ſediment in the Urine: then the ſore being more inlarged by the Ulcer, more large profuſions of blood often follow, and the fleſh it ſelf of the Reins being worn away, and by degrees eaten off, is voided with the Urine. I viſited once an ancient Woman, who daily voided with her Urine, for many months, pure blood in great quantity; beſides, as often as ſhe made water, ſhe uſed to void in great quantity pieces of fleſh, great gobbets, as it were the little Tubes of the Veſſels eaten away, that it was ſuſpected one of her Kidneys was all thus cut away from her body: yet afterwards by a vulnerary Decoction acidulated with Spirit of Vitriol, that bloody water was ſtaid, and this Woman lives ſtill well and in health. I knew another Matron, who uſed for a long time in making water to void at firſt blood with a purulent matter, and Membranes: then the bloody water ceaſing, for many years ſhe made a wateriſh Urine with a copious ſediment, and white like ſnot, ſinking down to the bottom of the Urinal. Afterwards when ſhe began to want that ſediment, a Feveriſh intemperance followed with pains wandring here and there, with a languiſhing of ſtrength, and other dangerous Symptoms: and when this ſick Woman was brought into danger of her life, a Tumor ariſing in her left ſide about her Reins, and ripening into a Boil or Sore, by reaſon of the large flowing out of the matter, freed her: but yet an hollow and ſinuous Ulcer pouring out a thin matter, remained in that place during her life: and being ſometimes healed up, would preſently break out again. Scarce two years after this Noble Lady having endured the ſuppreſſion of her Urine for fourteen days, became apoplectick and died. Her body being opened, her left Kidney was quite gone, in the place of it a membranous ſubſtance growing to the Loyns, infolding the extremities of the Veſſels and Ureter, was grown up: ſome prints or marks of the Ureter remained, but without any opening into the hollowneſs of the paſſage: yea a certain Ichor or ſeroſity dropping out from the little mouths of the emulgent Artery, was carried outwardly into that ſinuous Ulcer. The other Kidney was very full of ſandy matter and ſmall ſtones; beſides, near the top of the Ureter a ſtone about the bigneſs of ones thumb was fixed, whoſe extremity was ſo fitted and firmly impacted to the paſſage or cavity of the Ureter, that it ſhut it up juſt like a Tap, and quite hindred the paſſage of the ſerous juyce. The purulent matter comes into the Urine, not only from the Reins, but ſometimes out of the Bladder and Urinary paſſage diſtempered with an Ulcer; and ſometimes alſo a corrupt ſeed, or white flux, or menſtruous blood are poured into Urines from the Veſſels and genital parts, and produce in them preternatural ſettlements.

4. In the Urines of ſick people are often ſeen abundance of white Contents compoſed of moſt ſmall bodies; which, when they are ſetled, fill up above half the liquor, and make it white and duskiſh, the reſt remaining limpid, and thin in the upper region of the Urinal: this kind of ſediment is called Mealy, becauſe it is like water imbued with meal. Concerning this it is doubtfull, whether it proceeds from the whole maſs of blood, or only from the Urinary Viſcera. It appears by obſervation, that the ſame ſort of Urine is all ways made in the ſtone of the Bladder, alſo ſometimes by reaſon of the Kidney being oppreſſed with ſome great ſtone. I never ſaw ſuch a ſettlement in Urines without Nephritick diſtemper; wherefore I have thought it almoſt indubitable to be always a ſign of the Stone: And it ſeems that it ſhould wholly depend on the juyce or humour heaped up about the bulk or ſubſtance of the ſtone: For where the ſtone is fixed in the Kidney or Bladder, the nutritious humour is there perverted from aſſimilation, and degenerates into a more thick mucor, which uſes to be copiouſly heaped up; like Ichor, which by reaſon of a Pea put into an Iſſue, runs out plentifully. But this mucor or filth being waſhed with Serum, makes that white ſediment.

CHAP. VI.

Of Judgments to be given concerning the Urines of ſick People.

SO much for the Anatomy of Urines, wherein are unfolded their Elements and conſtitutive Principles, together with their chief Accidents, *viz.* Colour, Conſiſtence, and Contents, both what ought naturally to be in them *per eſſentiam* or eſſentially, and alſo what are wont to happen to them preternaturally, by reaſon of the body being ill affected. It will be eaſie for any one to accommodate this Hypotheſis to practice, and to give Judgment on Urines beholding them in the Urinal; for from what hath been ſaid it appears of what parts the Diſeaſes are made known by the inſpection of the Urines, and what the Urine ſignifies in each of them. Concerning this ſubject there hath been enough ſaid by Authors; I ſhall therefore only touch upon it briefly, and lightly paſs it over.

Although

Although the matter of Urine, *viz.* the Serum of the blood waſhes the whole region of the Body, and is circulated with the blood through all the ſeveral parts, yet it doth not lay open the conditſon and diſeaſes of them all, but only of thoſe to which it owes either the natural perfection and geneſis of it ſelf, or from which it receives every alteration: wherefore in ſome reſpect it ſhews the action and diſpoſition of the Viſcera ſerving to Concoction, and beſides denotes the temper and motion of the blood and humours in the Veſſels: but that any one ſhould pretend to know from the Urinal, and to divine a pain in the Head, an Impoſthume in the Throat, or any other Diſeaſe of any part, from whence nothing is communicated to the Serum, he ſhews rather his ignorance than the knowledge of any Diſeaſe.

Urines brought from ſick perſons ſometimes are wholly like thoſe of ſound peoples, and then they give no light to the diſeaſe or diſtempered part; but it may be lawful, having inſpected them, to ſay ſomething negatively, *viz.* that the Patient is free from a Fever, that as to the Ventricle and Concoction of the food, they are indifferently well: wherefore unleſs he be inclining to a Conſumption, or is ſick of an Impoſthume, or ſome other diſeaſe of the unity being broken; whatſoever it be, the diſtemper ſeems not very dangerous or hard to be cured.

But in the mean time I would not have him declare any thing raſhly, nor proceed farther than he can with ſafety return: for I have often obſerved in ſome moſt grievous diſtempers, *viz.* in a malignant Fever, when with loſs of ſtrength, a weak and unequal Pulſe, eruption of Spots, and other dangerous Symptoms, the Patients have been deſperately ſick, that the Urines as to the colour, conſiſtence, and Hypoſtaſis, have been laudable, as in ſound perſons, ſo that in ſuch a caſe the Phyſician by only viewing the Urine, as to his Prognoſtication had grievouſly erred: wherefore there is ſcarce credit to be given to the ſingle teſtimony of the Urine, unleſs there be other ſigns agreeable; but that it is a lyar in the Plague and malignant Fevers, and deceives: the reaſon is, that in thoſe diſeaſes the blood is leiſurely, and as it were ſilently corrupted, ſometimes without any great fervour: and ſo, although its liquor be infected by Coagulation, or by mortification or deadneſs; yet becauſe it doth not burn out much at the ſame time, ſo as to make an heap of aduſt matter, as of Aſhes, the Serum is little or nothing altered from its uſual diſpoſition or tenour: Beſides, ſometimes when in ſuch a ſickneſs the blood grows very hot, whatever of excrementitious is heaped up in its maſs, is preſently transferred to the Brain and nervous ſtock: wherefore the ſerous water being free from the preternatural contents, remains after its uſual manner; beſides this caſe, when the Urines appear of a deep colour, troubled, and without any ſediment, there is no reaſon why the Piſs-prophet ſhould make a Prognoſtication.

As often as the Urines of ſick people are unlike thoſe of ſound, either ſomething natural is wanting, or what is preternatural is added, or it happens both together.

1. There may be wanting Colour, Conſiſtence, Contents, and Quantity. If the Colour be more remiſs than it ſhould, and the Liquor paler, it indicates Crudity, and a defect of making Spirits, to wit, that the nouriſhing Juyce is not rightly concocted or exalted either in the Viſcera or in the Veſſels; ſo that the ſaline and ſulphureous Particles being carried out together, following the diſtribution as it were the diſtillation of the Serum, might throughly ſtick to the ſame, and impart alſo to it the tincture: wherefore ſuch Urine being viewed from theſe kind of Symptoms, you may unfitly divine, that there is a weight in the Ventricle, want of Appetite, evil Digeſtion, a tenſion in the Hypochondria, an unfitneſs for motion, ſleepineſs, difficult breathing, and a frequent palpitation of the Heart upon exerciſe, a pale colour, a ſwelling of the Feet and Belly, you may ſay they are in danger of falling (if not already fallen) into a Cachexy or Dropſie, and if it be a Maid, that ſhe is troubled with Longings and the Green-ſickneſs.

If the Colour of Urines be remitted in a Fever without a Criſis, it is a ſign that the fermentative matter or aduſt recrements of the blood are ſeparated from the boſom of the blood, and fixed ſomewhere, which for the moſt part happens in the Brain; and for that cauſe ſuch Urines uſe to foretel a Delirium or Phrenſie; in thoſe troubled with the Stone, a ſudden alteration of the urine into a pale and watry colour, denotes the approach of a Fit.

A copious and pale Urine often ſhews the too great reſolution or melting of the Salts, by reaſon whereof the ſeroſities are ſent away as it were in a flood from the whole body, and chiefly from the nervous parts; ſuch an Excretion ſometimes is healthful, and as it were critical, when the ſuperfluities happen only to be carried away: ſometimes it is ſymptomatick, and cauſes a great debility, to wit, becauſe the nutritious Juyce and the good humours are purged out.

If the Conſiſtence be thin, and the Liquor pale, it argues Crudity, want of Spirits, or too much Drinking, or the Nephritick diſtemper: if it be of a flame-colour, it is a ſign of an intermitting Tertian Fever.

If the Contents be wanting, and it be pale, want of Concoction is ſignified, and a Cachectick diſtemper of the body. But if it be of a Citron colour, and the conſiſtency mean, without Hypoſtaſis, you may ſuppoſe the Patient to have uſed too much labor or exerciſe; or to be frequently diſtempered with Sweats in the night, or perhaps to have an Atrophy, or general waſting, or to be inclining to a Conſumption.

If the Urine be continually made in a leſſer quantity than it ſhould, unleſs there be a larger tranſpiration, it is a ſign that the blood is not ſufficiently purged from the ſerous Juyce: wherefore there is a neceſſity that it become more watry, and that at length a Cachectical diſpoſition of the body, or a Dropſie be brought in. But if it be ſuddenly ſuppreſſed, or made with pain and difficulty, it is a ſign of the Stone or Gravel.

2. Something is added to the Urine, to wit, when the colour is heightned, and in the mean time the conſiſtency and contents ſhew themſelves in due meaſure, there may then be a ſuſpicion of a Feveriſh or Hectical diſtemper: perhaps ſome evident cauſe may precede, as the uſe of Baths, Heat, Surfeit, or immoderate Exerciſe, which might have heated the blood; or Cold may have heedleſly been taken, whence may ariſe a ſhutting up of the Pores, and difficulty of Perſpiration. If the Urine be of a Saffron-colour and tinges the Linen with yellowneſs, you may ſay it is the Jaundice: but if it be of a Saffron-colour or red without a Fever, and doth not dye Linen, it ſhews for the moſt part the Scurvy or Hypochondriack diſpoſition.

Though the Colour and Hypoſtaſis may be in good order, preternatural Contents are often in the Urine; therefore when it grows cold it is troubled, and makes a ſediment ſometimes white, and then there is a ſuſpicion of the blood's overflowing with filth, alſo of an impure Ventricle ſtuffed with excrementitious matter, or with Worms; ſometimes red, which often happens by reaſon of Tranſpiration being hindred, a Conſumption, and ſometimes by reaſon of a Surfeit, or the beginning of a Fever.

Preternatural and thicker Contents are ſometimes in Urines, ſhewing themſelves naturally, which denotes a diſtemper of ſome part about the urinary paſſages; whence Matter, Filth, Blood, the Whites, corrupt Seed, or the like, are mixed with the Urine: and you may eaſily know by asking how, and in what place the Patient is ill, what part is diſtempered; and the ſtraining the ſediments of thoſe urines will ſhew what the diſeaſe is, and you may be more ſure of the nature of the diſtemper.

When Urines have ſtood ſome time, copious white ſediments are thence made; it is not eaſie at firſt ſight to know from whence they come, *viz.* whether from the whole maſs of blood, or only from a particular bowel imployed for the preparations of the Serum or the Seed. For the impurities of the blood and nervous juyce being depoſited under a mealy ſpecies in the bottom of the Urinal, are wont to cauſe a ſuſpicion in the Phyſician of the Whites in Women, and of the Running of the Reins in Men: ſuch like contents are alſo ſeen in Urines, which proceed from the urinary and ſpermatick parts. Amidſt theſe ambiguities, leſt you ſhould gueſs raſhly and confidently by the Urine, and aſſert uncertain for certain things, and falſhood for truth, the difference of theſe kind of Urines ought to be indicated after this manner. If the contents be univerſal, and their ſigns be to be applied to the maſs of blood; for the moſt part theſe preſently after the making (unleſs ſometimes by chance in a Critical ſeparation) are wholly inconſpicuous (as in a thinner ſubſtance,) then the Urine being troubled by cold, they deſcend ſlowly to the bottom; and being ſetled, and the Urinal heated, they diſappear again. But if theſe white ſettlements are ſent from a particular neſt, they preſently diſturb and thicken the Urine newly made, are ſoon precipitated, and vaniſh not by heat. But that it may appear to what bowel theſe kind of particular contents ſhould be aſcribed, 'tis eaſily made known to Learned men by other circumſtances.

3. The Urine is ſometimes wholly altered from the natural ſtate; the colour and contents which ſhould be therein are wanting, and ſtrange things are in their place; then indeed is indicated that there is an intemperance in the whole body, and that the Concoction in the Bowels and Veſſels is depraved, you may ſay the Patient is ſick of a Fever; and thence by asking, you may learn and preſently pronounce that he is diſtempered with the Head-ach, Thirſt, Heat, queaſineſs of Stomach, want of ſleep, and by conſequence with other Symptoms.

It happens ſometimes, that the Urine declines from its natural ſtate, yet not to ſhew the diſtemper the Patient complains of, but either the cauſe of the diſeaſe, or the conſent of ſome other part with the diſtempered; as if any one ſhould complain of a cruel Head-ach, or trembling of the Heart, and make a watry Urine, that doth not denote thoſe diſtempers, but only a crudity in the Ventricle, and ſome obſtructions about the Spleen and Viſcera, which may be the cauſe of thoſe diſtempers: I ſay in this caſe, the Urine being inſpected, the chief indications are taken about the Method of Curing, and we muſt not uſe Cephalick or Cardiack Remedies, but either Catharticks, which cauſe Vomit or Purging, or Openers, and eſpecially Calybeats: But the Urine is ſometimes vitiated, and yet its ſignification is wholly a ſtranger to the diſtemper the Patient complains of, as if any one were ſubject to the ſleepy diſeaſe, or a Lethargy, and makes it red and full of preternatural contents, its inſpection ſuggeſts chiefly coindications, *viz.* that we inſiſt not on too hot, but temperate Remedies.

The chief uſe of Inſpection of Urines will be for the obſerving the ſtate and progreſs of every diſeaſe, as alſo the alterations towards health or death. For in Chronical diſeaſes, by daily inſpecting the Urine, is made known to the Phyſician, by what degrees the ſickneſs may increaſe day by day; at what time purging or altering Remedies will be moſt fit, and what Medicines will be moſt profitable; hence is to be obſerved, whether Nature prevails on the diſeaſe or not; and a moſt certain Prognoſtication may be drawn from hence, either of the hope or danger of health; to wit, according as the ſigns of Concoction or Crudity appear in the Urines. In acute diſeaſes, hence the ſtate and height of the Fever may be beſt known, at what time the Criſes may be expected, and with what ſucceſs: when it is beſt to inſiſt upon Evacuations, and when on Cordials. The Compaſs is not beheld with more certainty and diligence

by

by the Mariner or Steers-man, than the appearances of Urines ought to be obſerved by the Phyſician for fit times and ways of Curing.

Theſe were what I had to ſay concerning the Judgments of Urine, not collected from the vain Traditions of Quacks, but what are conſonant to reaſon and truth. Beſides I know there are ordinarily delivered by Medicaſters and Old women almoſt an innumerable company of Rules and Directions of Urine-divination, that the Urinal is no ſooner inſpected, but they will undertake to divine, whether it be a man or a woman that is ſick, how long they have been ſick, what their diſeaſe is, and whether the diſtemper ſhall end in health or death; whether the Patient be ſubject to the paſſions of Love or Sadneſs, whether a Woman hath conceived with Child or not, or whether it ſhall be a Boy or a Girl, and an hundred other the like; in which uſing a vain conjecture, they either impoſe by their confidence on the minds of the credulous, or (which is more frequently their cuſtome) by a cunning craftineſs they otherways ſift out the matter by inquiring, and falſly aſcribe it to their knowledge in the inſpection of Urine.

CHAP. VII.

Of the Examination and various ways of proving of Urines.

ALthough the buſineſs of the Examination and Inſpection of Urines ſeems commonly only a ſimple thing (*viz.* the Medicaſters and Quacks for the moſt part behold the Urine ſent in a Glaſs, ſhake it a little, and preſently give Judgment) yet to thoſe who honeſtly endeavour the recovery of the ſick, the matter ſeems a little more intricate, and they uſe to obſerve ſeveral circumſtances concerning Judgment by Urine; which being omitted, nothing indeed can be certainly or directly learnt in the Medicinal Practice from the Urinal. Moreover, in ſome diſeaſes, beſides the mere inſpection of the Glaſs, there are other ways of tryal to be had, by which, what lies hid in the Urines, and out of ſight, may be made clear: from whence ſome not unprofitably taking care of the ſeparation of Urine more accurately, have uſed to evapporate, diſtill, putrifie, and precipitate them. Wherefore we ſhall ſpeak briefly of the right manner of inſpecting Urine, and in ſome caſes of the Analyſis or ſeparation variouſly to be inſtituted.

When the Urine of the Patient is offered to the Phyſician, if it hath firſt ſtood for ſome time in the Glaſs, and if the liquor be clear, the Hypoſtaſis is as it were gathered into a little cloud, and if the reſt of the contents ſink down to the bottom, there is nothing more wanting, but that forthwith a prognoſtick ſentence may be given. But if the Urine be newly poured into the Urinal, or be troubled by a former ſhaking, you muſt ſtay till the confuſed parts be ſeparated, and the ſettlement have acquired its due place. If the Liquor be full of contents, and the Pores ſtraitned, it becomes troubled and dark, and the Glaſs muſt be put in a warm place, till the Urine grow clear again, and then let it be placed for ſome time near the fire, that whilſt the preternatural or more thin contents are abſorpt by the Pores dilated by the heat, the more thick may fall down to the bottom, and the filaments or little rags making the Hypoſtaſis, (if there be any) may be gathered together below, or in the middle region; for ſo will appear what is the power of Nature, and what of the Diſeaſe: Alſo in Fevers, the degree of heat and effervеſcency, the concoction or depravation of the nutritious Juyce, alſo the congeſtion or heaping together of the aduſt matter in the blood, and its ſeparation begun, or wholly fruſtrated, may ſomewhat appear by the ſignification taken from Urines; wherefore you ought to proceed after this manner, when the urine is brought from far, to wit, whoſe Particles are diſturbed by much ſhaking, unleſs it be kept for ſome time in a warm place, they will not eaſily get again their due place of poſition. But if you often viſit any Patient that keeps his bed, it will be convenient, that the urine newly made, and put into an Urinal, be placed near a Stove, where, whilſt it grows moderately hot, the ſeverall parts may, after the beſt manner, be diſpoſed to a ſettlement without any trouble or diſturbance.

Afterwards the Urine thus naked, and as it were diſrobed from any covering, is offered to the ſight, the next caution will be, leſt any of its Phænomena or appearances being accidentally contracted, and not properly belonging to it, may impoſe upon the Phyſician; which indeed ſometimes happens, by reaſon of alterations cauſed in them by food taken, and which chiefly conſiſt in the colour and ſmell of Urines, being variouſly changed beſides Nature, and the expectation of the Phyſician.

For it is an errour commonly committed, when the Urine being yellow, and tinging the linen by the taking of Rhubarb, Saffron, Sanders, and the like, undoubtedly to believe it a ſign of the Jaundice; alſo the urine being imbued with blackneſs by the taking of Caſſia, to attribute it to the melancholick Tumor or black Bile; alſo when the urine is deep colour'd by taking of Pulſe-broth, or a Decoction of Madder, or other drinks, we falſly ſuppoſe it to indicate a feverih intemperance. It often happens from the drinking plentifully thin liquor, the urine is leſſened of its high colour beyond expecta-

tion, and heightned by the drinking of ſtrong drink or hotter things: unleſs the Phyſician take notice of theſe kinds of mutations, he will give but a falſe Judgment concerning Urines by looking on them. When therefore the colour is changed in the Urines without any manifeſt cauſe, the manner of living muſt be inquired into, if that the alteration proceeds from what is eaten or drunk, that it may not be wrongfully aſcribed to the diſeaſe. A queſtion will here ariſe, why ſoraſmuch as moſt things taken in at the mouth, before they go into urine, wholly loſe all their colour; which being eaten, ſo pertinaciouſly impreſs a tincture to the Serum, that they paſs untouched through all the ſtrait turnings and windings of the paſſages? The reaſon or cauſe of which conſiſts chiefly in this, that ſome mixtures have the conſtitutive parts of their colour or dye very ſubtil, and thoſe highly volatile; wherefore theſe being taken only in a ſmall quantity, dye the whole maſs of the Chyle with their colour; and from thence the nutricious Juyce conveyed to the blood, aſcends coloured, and its vehicle, *viz.* the ſerous Latex, is ſent away ſtill dyed or tinctured.

What the odour of Urines of ſound people may be, is obvious to every one that can ſmell, *viz.* whilſt it is freſh made, it is not very ungrateful, by reaſon of the ſulphureous and ſaline Particles bound up in the ſubſtance of the liquor; when it hath ſtood ſo long, that the Sulphur begins to exhale, ſharpned with the Salt, the mixture being looſned, it putrifies and ſtinks grievouſly. Beſides we may obſerve, that ſometimes there ariſes from urines freſh made, a ſweet odour like Violets, and ſometimes they offend the noſe with a very ungrateful ſtink. The former doth not depend either on an healthful or unhealthful condition of the body, but is produced only from things taken: Turpentine, Nutmeg, and other Gumms and Spices taken in at the mouth, though of a diverſe nature and operation, impart a like ſuavity or ſweetneſs to the urine. The reaſon of this ſeems to be, becauſe in theſe kind of mixtures very many particles of the purer Sulphur (that is imbued with Spirits) are eminent; which, for that they are volatile, being confuſed with the Serum, are not contained in the bond of the mixture; wherefore the urine being made, theſe alone leap out, and not accompanied with others of the ſtinking urine, and ſo diffuſe a grateful odour; which, although it proceeds from divers kind of things eaten, yet remains ſtill after the ſame manner like Violets, for that in all, thoſe ſulphureous Particles are ſet free by digeſtion from the others joyned with them in the ſame concrete, nor are infected by different ones from the urine. But as to what reſpects the ſtinking urine, that ſometimes proceeds from an Ulcer about the Reins, Bladder, or urinary paſſages; ſometimes alſo it is raiſed from a too hot intemperance of the Reins, or of the whole Body; for when the Sulphur is deeply boiled in the Serum, its particles being ſharpned by the Salines, (for that they are leſs cloſely ſhut up) do preſently evaporate, and grievouſly affect the ſenſe of ſmelling; but beſides, ſometimes urines contract a ſtink from things eaten. For the Balſam of Sulphur, Garlick, Aſparagus, Cider, Rheniſh Wine, and many other things taken at the mouth, do cauſe a ſtrong ſmell in the urine. If the reaſon of this be demanded, we ſay that ſuch things which impart a ſtink to the urine, alſo provoke it in a more plentiful quantity: wherefore it ſeems that theſe ſort of things being taken, fuſe the blood, and greatly haſten the precipitation of the Serum; and when by this means the ſerous Juyce is pulled away as it were abruptly from the blood, the frame of the liquor is made lax, nor are its parts exactly mixed, nor contained in an equal bond of diſpoſition: wherefore when this urine is made from the body, its frame or ſubſtance being before looſned, the particles of the more groſs Sulphur (that is combined with Salt) preſently breathe out, and ſo diffuſe a ſtinking ſmell. For urine thus altered by things taken, ſeems very like to Lye, wherein Antimony or common Sulphur is boiled, and is afterwards inſtilled into ſome acid thing, becauſe in this Decoction, as alſo in ſuch ruine, the frame of the liquor being unlocked, the little ſulphureous bodies leap out, and affect the ſenſory with a ſtinking ſmell.

If that any one more curious in the ſearch of Urines, ſhall ſeek further than the examination of the ſight and ſmell, he may eaſily, by a divers manual operation, reſolve them into parts, and as it were diſſect them to the life, and thence draw Medicinal directions of no ſmall moment; for that in many Chronical diſeaſes where the Dyſcraſies of the blood are more exactly to be ſought into, that the proportion and temperature of Salt and Sulphur may be truly found in it, it is ſometimes convenient to evaporate urines, or to diſtil them, ſomething alſo is to be learned from them, being precipitated, or looſned by putrefaction. I knew an honeſt Woman greatly afflicted with a ſcaly filthineſs of the skin, which ſhe was wont to ſcratch off in great plenty, as it were a branny matter. Her urine being evaporated in a little Skillet, left ſticking to the ſides of the Veſſel, a cruſty and ſalt ſediment, like the excrement of her skin. Not long ſince I evaporated the urine of a Gentleman, grievouſly ſubject to convulſive motions and painful ſtretchings out of the Muſcles, in the bottom of which there remained a quantity of ſalt and tartarous matter, exceeding the weight of half the liquor. By this means it will be an eaſie thing to find the proportion of the ſaline Principle in the blood and humours: but whether this Salt be volatile, or becomes fixed beyond meaſure, the diſtillation of the urine will preſently ſhew; For if the Spirit (ſo called) be copiouſly drawn out of the urine, and that beſides the Salt aſcends into the Alembock, it is a ſign of volatilization: but the contrary to this argues the fixity of the Salt.

As the evaporation and diſtillation of the Urine ſhew the power of the ſaline Principle, ſo the precipitation, putrefaction, and Sulphur lay open the thicker contents of the Urine, as it were in weight and meaſure. As to the former, although the liquor of the urine be ſalt, and often big with contents, yet ſo as much as its ſaline Particles are not (as it is wont to be in moſt Menſtruums) either wholly in a ſtate of fixity,

fixity, or of flux, but for the moſt part volatile, therefore it is not eaſily nor preſently by any ſalt infuſion ſubject to putrefaction; the Spirit of Vitriol and other acetous things effect nothing: the Salt of Tartar ſtirs up a little peturbation. But the ſolution of Alum, for that it greatly conſtrains into a little ſpace, preſently diſturbs the whole liquor extreamly, and delivers all the contents of the urines, as they were thruſt out of their dens, to be ſeen openly by the eyes. Wherefore by this means, without any long ſtay for ſettlement, you may preſently know how much of ſulphureous and earthy matter is depoſed from the maſs of blood for nutriments in the bottom.

The putrefaction of Urines is wont to exhibit the ſeveral particles of every kind, yet more diſtinct, and diſpoſed as it were by themſelves; for if the urine be left to ſtand unmoved for many days in the Glaſs, the colour, odour, and conſiſtency will be very much altered; for the colour will be deeper, the ſmell ungrateful, and highly ſtinking; the conſiſtency thicker, and will have on the ſuperficies a downineſs or ſoaring, ſometimes whitiſh, ſometimes bluiſh: there will be alſo mixed in the bottom of the Veſſel a thick and copious ſediment, and oftentimes on the ſides ſandy or tartareous crud, of a whitiſh or Aſh-colour. From theſe kind of appearances, and as the urines ſooner or later putrifie, and ſome more or leſs altered from their former ſtate, it may be conjectured what the proportion of Salt or Sulphur may be, whether of them exceeds the other: alſo no unfaithful Judgment of the quality and plenty of the earthy matter or the contents may be taken from hence.

And thus, Sir, at length you have the Doctrine or Method of Separation of Urine, ſuch as our unskilfulneſs hath rendred it: I deſire you would be pleaſed not only to pardon the errours and barrenneſs of this Diſcourſe, but alſo to excuſe it in other things, becauſe at firſt writ by your perſwaſion, and then by your command and requeſt made publick. Wherefore pray take care of this child hardly brought forth and almoſt an abortive, and as it were expoſed and deſervedly laid at your door, without portion. Farewel.

Two

TWO Physical and Medical EXERCITATIONS,

VIZ.

I. Of the Accension of the Blood.
II. Of Musculary Motion.

THE FIRST Medical and Physical DISCOURSE.

Of the growing hot or inkindling of the Blood.

IT is long since I designed to Print my Meditations concerning the remaining Pathology of the Brain and Nervous stock: But when many Diseases of that kind affect the animal Spirits, and not rarely the whole Hypostasis of the corporeal Soul more immediately than the Humors or solid Parts; I therefore thought it necessary first to publish the Disquisitions of the nature of this Soul, and its manner of subsisting, and also of its Parts and Powers, that from these things rightly known, its preternatural Passions may at length be the better discovered. But concerning these very hard matters, and difficult to be unfolded, when I had begun to frame (as I think) probable and rational Arguments, I saw well they would be looked upon and laughed at by some as unusual things and Paradoxes; which indeed it becomes me not to take ill, but to let every one freely to enjoy his own sense, and to use in all things his own opinion and judgment. Among the many things conjecturally proposed by me, (which I could not avoid) two chief Arguments are opposed, to wit, that I had affirmed, that the blood for the continuing of life was inkindled, and that the animal Spirits, for the motive act, were exploded: which terms, though perhaps they may sound rough and strange to be applied to the animal œconomy; yet if any one shall weigh the Reasons and Arguments which do perswade to the truth of either opinion, I doubt not, but that there will be none who will not give their assent, or easily pardon me for mine. In the first place therefore, because there are so many opinions concerning the growing hot of the Blood, for that some attribute it to an innate heat, others to a flame in the Heart, some also to a fermentation of the bloody mass, and others to its inkindling; therefore I shall endeavour more narrowly to introspect the matter, and as much as I am able, to build upon a more certain Ratiocination, its genuine Cause, though very abstruse.

We

We have formerly diſcourſed concerning that Soul, which is common to the more perfect Beaſts, with that ſubordinate or more inferiour of Man, and have ſhewed it to be indeed Corporeal, and to conſiſt of two parts; the one of theſe rooted in the blood we called a Flame, and the other dwelling in the Brain and nervous ſtock, Light. As we ſhall here only treat of the former, I think it will be no difficult matter to make uſe of the ſame Reaſons and Inſtances, which truly conclude, or at leaſt very like truth, that in the firſt place the blood is animate or hath life: Secondly, that this Animation is in its accenſion or inkindling, or conſiſts in an affection moſt analogical to this.

1. Not only the opinions of Philoſophers, but the undoubted teſtimony of the Sacred Scripture plainly aſſerts the animation of the blood: to wit, the uſe of blood was forbidden in the Moſaical Law, for this reaſon, becauſe the Blood is the Life or Soul; which is alſo apparent by the obſervation of the moſt famous *Harvey*, for that its motion is to be obſerved by the eye, ſhews that it firſt lives and laſt dyes. For the greater proof of this, it is commonly known that Animals only live ſo long as the blood remains in its due plenty and motion; and that they preſently dye, if either too great a quantity of this be taken away, or its motion ſuppreſſed.

But as to the ſecond Propoſition, to wit, that the life or ſoul of the fervent blood depends upon its inkindling; this will appear probable, if I ſhall ſhew: Firſt, that the liquor of the blood ought to be very hot in the more perfect living Creatures. Secondly, that this growing hot can be produced or conſerved in the blood by no other means beſides accenſion or inkindling. Thirdly, that ſome chief affections, as it were proper paſſions of fire and flame, are agreeable to the life only of the blood growing hot. Fourthly and laſtly, theſe being clearly ſhewn, ſome other leſs ſignal accidents and properties, in which common flame and life agree, are added, and alſo we will unfold how and in what reſpect they differ among themſelves.

As to the firſt we affirm, that the blood is perpetually moved in all living Creatures; beſides in the more perfect it doth eſtuate or grow hot in act. Indeed its undiſcontinued motion is required, both for the conſervation of the diſpoſition of the blood it ſelf, whoſe liquor would otherwiſe be ſubject to ſtagnation and putrefaction, as alſo that being carried about in the whole body, it might be able to give a due tribute to all parts. For that the offices of the blood, at leaſt in the more perfect living Creatures, are divers and manifold, *viz.* to inſtil matter in the Brain and nervous ſtock for the animal Spirits to diſpenſe the nutritious Juyce into all the ſolid parts, to ſuggeſt to the motive parts an elaſtic Copula, and beſides to ſeparate all recrements and worn out Particles, and to put them aſide into convenient Emunctories.

But although the meer motion of the Blood in leſs perfect Animals, or at leaſt its moderate ſwelling up, ſuch as may be perceived in Wine and other Liquors agitated into Fermentation, is able to ſuſtain and perform the œconomy of Nature; to wit, for as much as both a crude nutriment is every where received from the river of the blood, though cool, continually flowing into all parts of the whole Body, and that fewer ſpirits and more thick, as it were ſeparated by percolation or ſtraining, enter the Brain and nervous ſtock with that plenty, that may ſuffice for local motion, and the Organs of the few ſenſes to be rudely actuated: yet the blood watering the bodies of more perfect Animals, require offices of a far more excellent kind; for it ought not only to be carried about with a continual and more rapid motion, but very much to ſwell up, yea actually to grow hot or effervent, to wit, for that end, that its frame or ſubſtance being very much looſned, it may more copiouſly ſend forth the reſpective Particles of various kinds, every where falling off from it, and may diſpoſe them here and there for the uſe and wants of Nature.

But firſt, for that the animal Spirits are continually to be ſupplied in great plenty from the maſs of blood, and that there is need for the elaſtic Particles requiſite for the locomotive function, to be thence perpetually poured into all the Muſcles, it ſeems very neceſſary that the liquor from whence theſe generous and manifold ſupplements are drawn ſhould be actually hot, or rather ſhould burn forth; to wit, that the aforeſaid Particles, not ſufficiently to be unlocked but by heat or burning, ſhould freely run out from the ſubſtance or frame of the liquor; which truly is manifeſt, becauſe from Wine, and alſo from the ſame bloody Liquor, and all other ſpirituous things, a ſubtil and ſpirituous humour is copiouſly drawn, but not to be performed by diſtillation without heat or fire. Yea the ſulphureous Particles, although they are leſs apt to be exhaled from any liquor, yet they moſt readily fly out by inkindling the ſubject. By theſe there is an apparent neceſſity of the blood's growing hot for the perfection of the animal as well as vital function: but that it may appear by what means this is done, to wit, whether by Accenſion, or by Fermentation, or by any other way, we ſhall firſt in general inquire, by what means, and for what cauſes any liquid things are wont to grow hot; then we ſhall conſider, to which of theſe the growing hot of the blood ought to be attributed.

Concerning theſe we ſay, that there are only three ways, or ſo many kinds of cauſes, by which Liquors conceive a heat, *viz.* firſt, by fire or heat being put to them, as when water is made to ſeeth or boil over the fire, or that it grows hot by the heat of the Sun, a Bath, or Stove, or by the diſſolution of quick Lime: inſtances of all which are commonly known. For the ſame reaſon Bath-waters ſeem to boil. For that we may inſtance in our own Baths, to wit, they are impregnated neither with Sulphur nor fixed Salt, as I have plainly experimented, by diſtilling and evaporating them, and by pouring into them precipitating Liquors; yea by diſſolving them with Sulphur, and many other ways. They moſt reſemble Lime-water, and they, as we believe, grow hot from a like cauſe, to wit, by imbibing the fiery little bodies ſome-

ſomewhere hid within the Earth. Of theſe, unleſs it had been ſuperfluous, we had here given a fuller deſcription, which may perhaps be done at ſome other time. Secondly, when ſaline Corroſives, which are of a diverſe kind, being mingled with themſelves, or with ſulphureous things, work mutually one on another with a great ſtrife and agitation of Particles, and oftentimes excite heat, yea ſometimes fume and flame; as when the Spirit and Butter of Antimony are poured to, or mixed with ſtygian Water, wherein lixivial Salts are melted, or with Oyl of Turpentine, or other diſtilled things: beſides when corroſive Liquors eat Metallick Bodies, they often grow hot. Thirdly, and the only way beſides (as I ſuppoſe) whereby a liquid thing is made hot, is when any humour, being very much imbued with Sulphur or Spirit, conceives a burning by putting a flame to it, and ſo grows hot by burning forth. This is ordinarily ſeen in oily or very ſpirituous Liquors, being inkindled and inflamed.

There remain indeed ſome other ways of Calefaction, to wit, Fermentation, Putrefaction, and Attrition, whereby more thick Bodies, or Solids, often conceive a fervour, but they produce not ſuch an effect in Liquids; whilſt the mealy Maſs or Dough is fermented, the active Particles being ſtirred up into motion, unfold themſelves on every ſide, and lift up the bulk or ſubſtance of the ſubject; in the mean time, for as much as the ſulphureous Particles being agitated with them, take hold one of another, and begin to be combined, a certain heat, though more remiſs, is excited; in like manner from Putrefaction, Dung or wet Hay get an heat, to wit, for as much as the ſulphureous Particles, within included, are very thickly heaped up together, then being combined together, they break out in troops; yet no Liquors, either thin or thick, whether they ferment or putrifie, do at any time grow hot; For Wines, whilſt in fermenting they break in pieces the ſides of the Tun, or overflow the top of the Veſſel with a great noiſe and ebullition, do not actually grow hot, yea not ſo much as grow warm. The blood being let out of the Body, and placed in convenient Glaſſes, either to ferment or putrifie, doth not get any actual heat; yet in truth we grant the Blood in living Creatures to be fermented, and by fermenting to be putrified, yea and ſome other offices of the animal œconomy to perform the ſame: moreover, we have formerly ſhewed from its Fermentation being hindred, or too much increaſed, or otherwiſe depraved, divers kinds of diſeaſes to be produced: yet we deny the heat of the blood to be excited by Fermentation. Becauſe neither the blood of more frigid Animals, nor Wines, nor any other Liquors, though agitated with the higheſt Fermentation, are for that reaſon actually hot. And indeed the reaſon ſeems evident enough, to wit, becauſe the ſulphureous Particles being raiſed up in the more thick ſubjects, though they lay hold on one another mutually, and being more thickly heaped together, raiſe up heat: yet in Liquids, the ſame kind of Particles, however ſtirred up or agitated, are immediately disjoyned by the watry coming between, and are hindred from their mutual embrace and combination; ſo that they cannot of themſelves produce an actual heat; For the ſame reaſon, hard bodies being rubbed one againſt another, or violently knocked or bruiſed, do not only produce heat but oftentimes fire; when as yet Liquids, however ſhaken and agitated, do not grow warm. Therefore as there are only three ways, whereby actual heat may be begotten in all Liquors, we ſhall inquire to which of theſe the heat of the Blood may be aſcribed.

Firſt, Some ſay it is the firſt way, from the opinion both of the Ancients, and of ſome of the Moderns: the Blood is ſaid to grow hot, by reaſon of ſome hot thing put to it, to wit, whilſt thoſe affirm an innate heat, and theſe a little flame to be placed in the Heart, and to heat the blood paſſing through it; but either of theſe opinions eaſily fails, from which it is clear, that the Heart is a mere Muſcle, nor doth contain in it ſelf any tinder or matter for a flame or heat (I know not how) implanted, fit for their continuance. For though it be confeſſed, that on the continual motion of this Bowel, (which is only animal) the Circulation of the Blood doth depend, yet the Heart borrows heat altogether from the blood, and not the blood from the Heart.

Secondly, as to what reſpects the ſecond way of making hot a liquid thing, to wit, whereby a great heat is excited by the mixing of ſaline Corroſives together, or alſo oily, or by corroding a metallick Body, I think there is none that will ſeriouſly aſſert, that the blood grows hot from ſuch a cauſe; for that its liquor, in its natural ſtate, is always homogene, and although it be ſtuffed with plenty of Salt, it is however with that which is volatile, gentle, and benign only; But there is not to be found, either in the heart or any other place a ſaline or any otherwiſe heterogene Mine, whereby the bloody liquor, by working or corroding, may get or conceive an heat; to wit, it behoves either ſuch a Mine or the Body to be corroded, to be perpetually renewed, becauſe the ebullition and heat raiſed up by the ſtrife of Salts, ceaſes as ſoon as the Salts are combined, or the Body corroded. If at any time the ſaline Particles of the humours in our Body depart from their right temper, and become enormous and unbridled, for that reaſon the blood as to heat and motion, enters into ſome irregularities; yet it ſeems impoſſible, that it ſhould originally and perpetually become hot by the congreſſion, and ſtrife, or corroſion of the Salts.

Thirdly, As to the third way, whereby Liquids are made hot, though it may ſeem an uncouth ſaying, That the blood is ſo inkindled, yet ſince we cannot attribute it to any other way beſides, what ſhould hinder from attributing its heat to this Cauſe? And the rather, for that the proper paſſions of Fire and Flame are agreeable to the life of the Blood alone.

For indeed theſe three things are chiefly and principally Eſſentials, requiſite for the perpetuating flame. 1. That there be granted to it, as ſoon as it is inkindled, a free and continued acceſſion of the Air. 2. That it may enjoy a conſtant ſulphureous food. 3. That its recremens both ſooty, as alſo the more thick, be always

always ſent away. So then if I ſhall ſhew theſe things to agree after the ſame manner with life, as flame, and to thoſe only, without doubt, I think that life it ſelf may be eſteemed a certain kind of Flame.

In the firſt place therefore, that a flame may be inkindled, and remain inkindled, there is need of a free and undiſcontinued acceſs of Air, and that not only, that the vaporous Effluvia's, threatning the ſuffocation of the flame, may be carried away, and always depart, but much rather, that the nitrous food neceſſarily requiſite for the burning of any thing, may be ſupplied by the Air. For indeed every ſublunary fire, and eſpecially flame, is compounded or made up altogether of ſulphureous Particles, breaking out in heaps from a combuſtible Body, and of nitrous Bodies, which every where flow in the Air, meeting with them: when Particles of Sulphur, breaking out ſlowly or interruptedly, get to themſelves a few nitrous, only planted near them, a fire is uſually produced, ſuch as is ſeen in a burning Coal: But when the former going away more impetuouſly, either of their own accord, or forced by blowing, preſently lay hold on very many nitrous Particles flowing round about in the whole circuit, a flame ariſes. In truth the whole region of the Air is abundantly ſtuffed with nitrous little bodies, which are every where ready for the conſtituting of fire and flame, and they being any where inkindled, meet them after the manner of a flood, although not always after the like manner or meaſure, becauſe it is obſerved at ſome times, eſpecially in the Winter-cold, when the Air abounds more in Nitre, that fire or flame doth more ardently burn, and diffuſe farther its heat: on the contrary, in rainy weather, as alſo when the beams of the Sun ſhine upon the fire, and ſo diſſipate the Nitre of the neighbouring Air, the fire is ſo dull'd, as is commonly ſaid, that it is extinguiſhed by the Sun. If at any time the nitrous Particles of the Air are excluded from the ſulphureous of any ſubject breaking out in the inkindling or burning, the fire and flame quickly periſh; which appears, becauſe this or that being put into a Glaſs, after the Air is ſucked out or excluded, they preſently expire. Further, in the open Air, although a naked fire propagates a fire in a fireable matter by mere contact, yet a flame is hardly inkindled without a flame be put to it, or a very ſtrong fire: becauſe, for the ſtirring up of a flame very many nitrous Particles of the Air, implanted round about, ought to be inkindled at once; as if Nitre and common Sulphur being pounded together, be commixed (becauſe both Incentives agree) even the leaſt ſpark falling into ſuch a mixture begets an highly impetuous flame, which deſiring no farther a nitrous food, is inkindled or burns under water, in a place void of air, or in any place as freely as in the open Air. In like manner, the leaſt ſulphureous things, as a bit of ponderous wood, being caſt into a red-hot Crucible, in which Nitre is fuſed, the ſame at firſt touch preſently conceive a flame, and continue till it be wholly conſumed: But that fire and flame being included in a place empty of air, expire by reaſon of the food of Nitre being drawn away, rather than choaked by their own proper ſmoke, the Illuſtrious Mr. *Robert Boyle* hath moſt clearly demonſtrated by very many Experiments. For a Candle being lighted, and put into a capacious globe of Glaſs, and the Veſſel ſtopped up: aſſoon as the air was ſucked out by a wind-inſtrument, the flame did expire. Moreover, he obſerved, what concludes for our Hypotheſis, that the flame contracted it ſelf according to all its dimenſions, aſſoon as ever the Engine began to ſuck, then after the ſecond or third draught of the drawn forth air, the flame about the utmoſt extremities appeared very blue, and to go back more and more from the Tallow, till at length getting to the top of the ſnuff it expired: the ſame Candle being again lighted, and ſhut up in the recipient, this worthy Gentleman tryed how long it was able to ſuſtain its light, when the air was not exhauſted, and he found it to endure much longer lighted than before. From theſe it clearly appears, that the flame ſhut up, expires not ſo much becauſe it is ſuffocated by its own proper ſmoke, as becauſe it is deſtitute of the nitrous food of the Air. For in the former Experiment the air being exhauſted, there was more ſpace for the ſmoke and fume, that the flame might not be ſtifled, and yet this dyed ſooner, the Recipient being empty, than the ſame being full of air; beſides, the flame dying became bluiſh, for as much as it is participated of more Sulphur than Nitre; and it left the Tallow, and expired at the top of the ſnuff, for that it followed its moſt neceſſary food as far as it was able, to wit, the nitrous Particles of Air. The ſame Experiment ſucceeded alike in live Coals, *viz.* the naked fire, after the food of Nitre was drawn away, ſuddenly dyed. Here alſo it doth what the flame of a Candle doth in Mines or Caves under ground, where the nitrous air is wanting or diſpelled, at firſt it becomes more contracted and blue, and then a little after expires.

Phyſ. Mec. 50. *Exper.* 13. *Exper.* 78.

I have been more large in this Argument, becauſe there is for both the like neceſſity of drawing in of the air, after the ſame manner, for the ſuſtaining the life of the Blood, and for the continuing of flame. For the more hot Animals, if they are hindred from reſpiration dye quickly, wherefore the ſame means of killing is moſt ready and common to ſhut up the breath, which being wholly obſtructed, life periſhes as a flame. If it ſhould be objected, that thoſe choaked do dye, becauſe the ſoot or ſmoke being retained, blow up and intumifie the bloody maſs, which for that reaſon, the bulk or ſubſtance being increaſed, and made almoſt immoveable, fills the boſom of the heart, and hinders its motion: I ſay, that this is improble, becauſe if the Arteries, every where in the Limbs and about the Neck, be ſtrained hard together with Ligatures, that the blood being ſtraitned as to the compaſs of its circuit, be very much ſtopped about the *Præcordia*, (more certainly than can happen from the mere retained ſmoke) yet for that cauſe death neither preſently follows, nor any deadly Symptoms. That this happens in thoſe that are hindred from reſpiration, becauſe the vital flame of the blood is wanting of the nitrous food of the Air, rather

than overthrown by its proper ſoot or ſmoke being detained, the moſt Famous *Boyl* alſo by his Experiments hath put it out of doubt; for he hath obſerved, that hot living Creatures being put *Exper.*41. within a glaſſy Globe, and ſhut up, did far ſooner expire, the air being drawn away from them, than the ſame being left within it, though in the former caſe, there was more ſpace left for the receiving the ſmoke, leſt the retaining of it might conſtipate the blood: yet however, if the heat of the Blood ſhould ariſe from Fermentation, or the congreſſion of diſſimilar Particles, or from an ebullition, by reaſon of admitted heat, or from any other cauſe beſides accenſion, it is ſo far that that effect could be inhibited or ſuppreſſed by reaſon of the air being excluded, that on the contrary it would rather for that cauſe become more ſtrong or intenſe. For it appears, by a common obſervation, that Liquors chiefly fermentable, the more ſtrictly they are kept in the Veſſel, the more they grow hot, and the air being admitted through ſome vent-hole, they preſently ceaſe from their fury. Moreover, Mr. *Boyl*'s Experiments clearly ſhew, that the effervefcencies or growing fervent, ſtirred up by the ebullition of unlike Particles, or by corroſion, alſo the boiling up of hot water in a glaſſie Sphere, are above meaſure increaſed after the air is ſucked out, *Experimen. Phyſicom.*41,42,43. That moſt ingenious Tract of the aforeſaid Author ſupplies us with many Experiments, whereby it is abundantly manifeſt, that the inteſtine motions of thoſe Particles, and almoſt of every thing, beſides fire and life, are very much heightned or made ſtrong in the ſpace emptied of air; but their act, preſently after the air is withdrawn, is extinguiſhed: hence we may conclude, the life of a living Creature to be either fire, or ſomething analogical to it. The like to theſe is yet more clearly obſerved by the diggers of Minerals, who ordinarily experiment in ſubterranean Caves, where either the Nitre is wanting, or is driven away by ſome ſtrange damp or vapour, ſo that they are in danger of being ſtifled or ſmothered, at the ſame time the flame of the Candle is diminiſhed, becomes blue, and at length expires.

The ſecond thing requiſite to ſuſtain a flame, is a conſtant ſupply of ſulphureous food, whereby it may continually be fed, which being ſubſtracted, or by reaſon of ſome incongruous mixture depraved, the flame is extinguiſhed; as is perceived in a Lamp, which for want of oyl, or water poured in its place, expires: further, as this ſulphureous food is more or leſs ſuggeſted, ſometimes more plentifully, ſometimes more ſparingly, the flame being more or leſs intenſe, is ſometimes produced clear, ſometimes ſmoaky; in the mean time, the food being conſtantly conſumed by burning, goes away partly into vaporous Effluvia's, and partly into aſhes, which are made up of ſome Particles of Earth, Salt and Sulphur: But it is much otherwiſe in Liquors expoſed to Fermentation, to which if new Particles be continually adminiſtred, and the old ones depart, the Fermentation is hindred or diſturbed.

In like manner, as in Flame, the blood of the hotter Animals (and this only in all natural things, beſides fire) requires a conſtant and copious ſulphureous food; and that being quickly worn, is for the moſt part conſumed in vaporous Effluvia's, a *Caput mortuum* being left of Earth, Salt, and ſtinking Sulphur: In the mean time from its food conſumed by burning, it diſpoſes other Particles for other uſes. That the life or flame of the blood doth continually want aliment, there is none but daily finds it in himſelf: For if that be for ſome time denied, the vigor of the blood is diminiſhed, yea, and conſuming the ſolid parts, it ſnatches into its boſom their remnants, and other humours of the Body whereby it may be fed. If the nutriment daily ſuggeſted from things taken, be too thin and watry, the fervour of the blood, like flame without food, uſes to be remitted; but if the food be very ſulphureous and ſwelling with a vinous Spirit, and plentifully taken in, the blood is preſently inflamed, and often breaks out into a Fever, as it were an open burning. In the interim, out of that food of the blood exhauſted or conſumed, as it ſeems by accenſion, hot Effluvia's full of ſoot and vapour go away, which according to a juſt account, far exceed all the other excrements of the Body; and that their nature is plainly fiery, the frequent burning of the mouth and tongue, and infecting them with blackneſs like the ſoot or ſmoke of a Chimney, witneſſes; beſides from the inflamed blood aduſt Feces, like a *Caput mortuum*, are ſent into the Bladder of the Gall, Spleen, and perhaps into other Emunctories.

Thirdly, That inkindled Flame may for ſome time continue, there is need of continual ventilation, to wit, that its ſooty Effluvia's may ſtill fly away, which elſe being detained and heaped together thereabouts, will ſuffocate the fire, becauſe by obſtructing the Pores of the inflamed Body, they hinder the eruption of the ſulphureous matter to be inflamed. Although this condition doth often interfere with the other more potent, *viz.* the neceſſity of nitrous food to be ſo drawn in from the Air, that it can ſcarce be diſtinguiſhed from it; yet we may plainly perceive, from the detained ſoot gathered together about the ſnuff, the light to be put out: for which cauſe a Lamp, whoſe wick is made of plumous Alum or other incombuſtible matter, will not (as it promiſes) endure any long time, becauſe the ſoot ſticking to the wick, hinders the acceſs of the oyl to the flame; for this reaſon blaſts of wind from the Air wiping away the ſootineſs, doth not only render the flame more clear, that is free from fume and thick vapour; but food being ſufficiently given to it, it becomes more durable.

Even as Flame, the life of the Blood requires alſo continual ventilation; to which end, beſides the greater breathing places of the Breaſt, innumerable leſſer, *viz.* the Pores of the skin gaping every where through the whole Body, do ſend forth Effluvia's departing plentifully from the boiling blood; which if it happens to be hindred, or too cloſely ſhut up, the blood will grow exceſſively hot, being as it were beſet with fume and vapour: beſides, there is need to ſhorten its circuit, that paſſing through the Lungs with a more frequent turn, it might there, as much as it can, diſpel all its ſoot or ſmoak.

When

When the Heavens are heated the Air ſeems as it were immoveable and to ſtagnate, we are wont very much to grow hot about the *Precordia*; for that the Blood being fed with a more ſparing nitrous food, doth not burn ſo clearly, but glows with a more ſuffocating and intrinſick burning: further, for that the Particles of the Air being leſs nimble, when they are inſpired and expired or breathed forth, do not ſo readily convey away the vaporous Effluvia's of the blood; hence it is, that we fan the Air, that it may be made more moveable, and carry away more quickly and plentifully the ſoot or ſmoke from our *Precordia*.

There yet remain ſome other ſmaller Conſiderations of Fire and Flame, reſpecting indeed not ſo much the Eſſence, as the production and extinction of either, which, whether and how far they may agree with the life of the Blood, we ſhall briefly inquire into.

Fire or Flame is produced two ways, *viz.* either it is kindled from another fire or flame, or begot by an inteſtine motion of ſulphureous Particles. We have largely ſhewed the Species of either, and the manner of their being made, in our Tract *of Fermentation* (only we omitted there, that the acceſſion of nitrous food was neceſſary for the ſuſtaining it) even as flame, the life alſo of the hot or warm Blood, we have obſerved to be produced by a twofold way, to wit, it is either inkindled from another life or ſoul, as in Creatures that bring forth alive; or intrinſecal Particles prediſpoſed to animation, are at length raiſed up to life with the blood by a long cheriſhing of external heat, as in oviparous or egg-laying Creatures.

If it be further demanded, when and how the vital Flame is kindled firſt in the Blood? I ſay, ſome ſmall beginnings of it are laid up from the conception it ſelf in the Genital humour, to wit, when the rudiment of the bodily Soul culled out from the Souls of the Parents, as a little ſpark ſtricken from thoſe flames, is hid in a convenient matter; which being from thence raiſed up by the Mothers heat, begins a little to glow and ſhine, and afterwards being daily dilated with the blood brought forth, and leiſurely increaſed, is equally extended with the Body, which it actuates and animates. But yet as long as the young one is included in the Egg or Womb, the vital fire, getting very little or ſcarce any aery food, doth not yet break out into open flame, but like a Brands-end covered over with aſhes, burns only ſlowly and very little, and ſpreads abroad ſcarce any heat, wherefore both the formation and increaſe of the Embryo depends very much on the Mothers heat, or the cheriſhment of ſome other analogical thing, whereof being deſtitute, it periſhes: but as ſoon as the young one is born in due time, and begins to breathe, the vital fire preſently receiving the nitrous food, largely unfolds it ſelf, and an heat or effervеſcency being raiſed up through the whole bloody maſs, it inkindles a certain flame; and becauſe the blood then firſt ruſhing into the Lungs, having there gotten an acceſſion of Air, begins to burn, the fleſh of that Bowel, at firſt reddiſh, is ſhortly changed into a whitiſh colour, like burnt aſhes, and the blood it ſelf undergoes a notable alteration; for what did flow of a dark Purple colour into the *Pneumonick* Veſſels from the right ſide of the Heart, returning from thence preſently out of the Lungs, becomes Crimſon, and as it were of a flame-colour, and ſo ſhining, paſſes through the left Ventricle of the Heart and the appending Arteries.

Indeed that in Creatures new-born, the colour of the Lungs is ſo ſuddenly changed, I think it ought to be attributed to the Blood, there at firſt more openly inkindled, and their fleſh as it were ſomewhat roaſted; although the mere inflation of the Lungs in a dead Embryo produces the like effect, becauſe the Membranes of the Lungs and the Parenchyma being diſtended and increaſed into a greater capacity, ſhake off the ſtagnating blood, and ſo draw it away into little and ſcarce to be diſcerned rivulets.

As to the Colour of the Blood, ſo variouſly changed into circulating from a dark purple to a crimſon, and from this to that, I ſay, that the immediate cauſe of this is, the admixtion of the nitrous Air with the Blood; which certainly appears, becauſe the change into a crimſon, begins in that place where the Blood chiefly gets the acceſs of the Air, *viz.* whilſt it is transferred out of the Arteries into the Pneumonick Veins; for in thoſe it appears of a dark Purple, in theſe every where florid, as the moſt Learned Doctor *Lower* hath obſerved. Further, it yet farther appears, that this alteration of the colour proceeds from the admixture of the Air, becauſe that crimſon colour follows in the ſuperficies of all blood, let out of the Veſſels by reaſon of its meeting or mingling with air: and if the flowering or top be taken away, another preſently ariſes. Beſides, the Blood being let out of a Vein, and very much ſtruck with a ſwitch or rod, it becomes crimſon through all: and in like manner the blood of living Creatures ſhines at firſt within the Pneumonick Veins, to wit, preſently after the influx of the Air by the Wind-pipe; and from thence, by reaſon of the ſame Particles of inkindled air being yet retained, it paſſes through all the Arteries ſtill florid; in the mean time, from the Nitre of the Air mingled with the ſulphureous Particles, and burning with them, the blood being greatly rarified, and in truth expanded into flame, impetuouſly ſwells up within all the paſſages of the *Pneumonick* Vein and the great Artery, ſending from it ſelf copious breaths and hot Effluvia's; but being dilated towards the ends of the Arteries, and returning towards the Heart, that it may enter more cloſely into the little mouths of the Veins, it lays aſide its turgid and burning aery Particles, and being preſently made more quiet and half extinct, and ſo both its vigour and alſo its colour being changed, it returns through the paſſages of the Veins that at length running into the Lungs, it might renew its burning. After this manner, that the inkindled blood might flame through the whole Body with a perpetual and equal flame, and ſucceſſively renew its burning in all its Particles, it ought to be carried about by a perpetual courſe from the neſt of its accenſion

into all parts, and from theſe to that. For this end the Machine or Engine of the Heart was needful, as a Pin or Cock, which being made with a double boſom, might receive in it ſelf from the whole Lungs the blood freſh inkindled, that it might preſently drive forward, whilſt burning, into every part of the whole Body, and might then receive the burnt and half extinguiſhed blood returning from the whole Body; which being imbued with new inflammable juyce, it might deliver to the Lungs to be re-inkindled.

In performing this task, although the Heart be a meer Muſcle, and exerciſed only with an animal motion, ſeems to ſerve alone for the Circulation of the Blood; yet in the mean time, it ſo much helps to moderate the accenſion of the Blood and its burning, according to the rage of the paſſions, and to direct other works and uſes of the animated body, that we have thought the vital or flamy part of the Soul to have its chief, and as it were Imperial ſeat in the Heart and Lungs, in every diſtemper or affection, as of Grief, Joy, Fear, and the like; alſo in the fits of Diſeaſes, the Heart is diſpoſed after a various manner, and hence it comes to paſs, that the blood flowing in fluctuates, and is inkindled with a divers rage; of which there will be a more opportune place of diſcourſing, when we ſhall treat of the Paſſions.

Whilſt we conſider that the burning of the Blood, and for that reaſon the vital or flamy part of the Corporeal Soul doth not appear lively or vigorous in all, nor ever after the ſame manner or meaſure; yet it exiſts according to the various conſtitutions of the blood, to wit, as it is more or leſs ſulphureous, ſpirituous, ſaltiſh, or watry, yea and according to the divers conſtitutions and conformations both of the food, with which this flame is nouriſhed, as alſo of the little ſpiracles or breathing holes, by which it is eventilated; and further, of the Heart it ſelf, whereby it is agitated and driven about here and there; the accenſion of blood varies alſo in every one, by means of ſeveral other accidents, to wit, as its flame is ſometimes great, clear and expanded, ſometimes ſmall, contracted or cloudy, ſometimes equal and in order, ſometimes unequal and often interrupted, yea and it becomes ſubject to many other mutations; alſo becauſe the Soul it ſelf having gotten a various nature or diſpoſition, it conceives divers affections and manners, whereof we ſhall ſpeak hereafter; for as much as it is not a little thing, that the diſpoſition of the whole Soul depends upon the temperament of the bloody maſs, and the degree and manner of its accenſion or inkindling.

It clearly appears, from what hath been ſaid, that Fire and Life do dye or are extinguiſhed alike many ways, to wit, there is an end of either, if the acceſs of nitrous food, or the departure of Effluvia's be hindred, or if the oily or ſulphureous aliment, requiſite to either, be conſumed, too much withdrawn, or perverted from its inflammable diſpoſition; of each whereof it is ſo clearly apparent, that there needs no farther explication.

Thus far we have ſhewn, that the Life of the Blood, or that part of the Soul growing therein, is a certain kind of Flame; let us now ſee by what means it is diſpoſed to burning, and how near it comes to the ſimilitude of a burning Candle or Lamp.

A common Lamp, whether deſigned to give heat or light, for the moſt part is wont to be made after this manner; to wit, the Oyl flowing perpetually to the wick, gives continual food to the flame; wherefore as there is but one fire-place or hearth only of light and heat, the action of either is limited only to one place, and ſo often as there is need of more places at once, or divers parts of the ſame ſpace or body to be illuminated or made warm, we place here and there divers lighted Candles or Lamps. But if an Inſtrument made with great artifice (ſuch as is truly an animated Body) with one liquor only contained in it, ſhould be made hot throughout the whole, and to be kept always warm, it ought not only to be lightly inkindled in the wick, but in the whole ſuperficies, and derived by fit Tubes or Pipes to all the parts of the Machine, then the burning liquor ought to enjoy, proportionably to all its parts, an acceſs of nitrous Air, and to lay aſide Effluvia's and other recrements, and ought alſo to have a ſupply of that conſtant expence: theſe kind of offices are not to be performed any where up and down, but only in ſome ſet places; therefore the burning liquor ought to be carried about through the whole with a perpetual turn, that all its portions might enjoy ſucceſſively all thoſe priviledges, and at once heat the whole capacity of the containing Machine, to wit, both the inward and outward receſſes. Indeed ſuch a Bannian or Bathing Engine, artificially made, might aptly repreſent the real Divine handy-work of the Circulation of Blood, and what burns in it, the Life-lamp.

But it may be objected, that the Blood ſeems not to be inflammable of its own Nature; further, ſince there is no flame or effervency of this heat to be ſeen with the eyes, it may well be doubted, whether there be ſuch a thing or no. I ſay firſt, That the Chymical Analyſis of the Blood ſhews very many particles of Sulphur and of Spirit, yea a plentiful ſtock of inflammable Oyl, which are however mixed with other more thick Elements, in a juſt proportion, to bridle their too great inkindling; to wit, that this liquor might flame out by little and little, and only through fewer parts, for the conſtituting of a benign and gentle Lamp of life: wherefore the Blood being let out of a Vein upon a burning fire, doth in ſome meaſure burn, though it is not like the Spirits of Wine, or Oyl of Turpentine, turning all into a flame; beſides, the whole maſs of Blood, as the Oyl of a Lamp, ought not to be fired; yea its burning is inſtituted for that end, that whilſt all the Particles of the Mixture being freed, ſome ſulphureous and ſpirituous are conſumed by burning, others more ſubtil being ſent in Troops, might ſerve for the neceſſary uſes of the animal Regiment; and alſo others more thick or craſs and nouriſhing, as it were boiled or roaſted, might be diſpenſed for the cheriſhing all parts; beſides, that all the dead, or worn out, and excrementitious may be ſent away by fit or convenient ſinks, and others conſtantly ſubſtituted in their places by nouriſhment.

But

But in the interim, that the vital Flame, which deſtinated to ſo many offices, we ſuppoſe to be inkindled in the Blood, (otherwiſe than the common flame, which is plainly conſpicuous) appears not at all, a probable reaſon thereof may be given; as it is moſt thin, and burns in the Heart, and its depending Veſſels as it were ſhut up in Receptacles, it doth not clearly flame out, but perhaps remains in the form of ſmoke or a vapour, or breath; yea, although the Blood ſhould openly flame out, yet it might be ſo done, that its ſhining being moſt thin, may not be perceived by our ſight, as in the clear light of the day we cannot behold a glowing red-hot Iron, nor ſhining ſpark, nor falſe fires, nor rotten wood, nor many other things ſhining by night; why then may not the vital fire, even thinner than they, quite eſcape our ſight? Although ſometimes hot living Creatures uſe to ſend forth a certain fire or flame only conſpicuous by night: For we have known in ſome endued with a hot and vaporous blood, when they have put off their inner garments at night going to bed near a fire or Candle, a very thin and ſhining flame to have ſhewn it ſelf, which hath poſſeſſed the whole inferiour region of the Body. The reaſon of which affection ſeems wholly the ſame, as when the evaporating fume of a Torch juſt put out, is again inflamed by a light inkindling, and manifeſtly argues that another flame, the root of this extrinſick one, lyes hid within the Body. For this very cauſe it is, that from the Mains of Horſes, and the Skins of Cats, or other hot Animals being ſhaken, little ſparks as it were of fire leap out, and often flames, only conſpicuous in the dark ariſe. Beſides, we here take notice in a burning Fever, cauſed by immoderate drinking of Wine or ſtrong Waters, that the Blood, as the flame of it is very much increaſed, doth grow exceſſively hot, and ſuch are wont to emit dry breaths, and ſharp Effluvia's of heat, not like thoſe that proceed from fermenting or boiling Liquor, but only inflamed. That which ſome in Fevers have imagined to have ſeen or obſerved, even burning fires and flame in the eyes, argues indeed that the flame of the blood is very ſtrong, and alſo that it penetrates the incloſure of the Brain. I knew a certain ingenious Man of a very hot Brain, who affirmed, that after a very plentiful drinking of Wine, he was able in the darkeſt night to read clearly; from hence alſo may be collected, how the accenſion of the blood, like that of burning Liquors, is to be increaſed or made ſtronger, *viz.* by an agitation of the parts, and a more plentiful affuſion of ſulphureous food.

But that in the hot blood of living Creatures the Properties, Affections, and many other accidents of Fire or Flame are found without the manifeſt form or ſpecies of it; what if we ſhould ſay the cauſe to be, for that the vital flame of the Blood is ſubjugated, or made ſubordinate to another form, *viz.* to the corporeal Soul? Wherefore, although it retains the chief qualities and affections of common flame, yet it loſes the ſpecies of flame or fire; for in every natural mixture, the ſuperiour form exerciſes a Right and Dominion over all included Particles whatſoever, however fierce and untameable they may be in themſelves, and ſtripping them of their ſpecies, ordains and diſpoſes them to peculiar actions in that proper Concrete: when the form of fire excels, that bright burning, that it might propagate largely its ends, deſtroys and conſumes all inflammable objects. But if the form of the corporeal Soul be induced upon the fire, kindled within the blood, it burns forth without fulgor or ſhining, or deſtruction of the ſubject, and is inviſible, and as it were ſubjugated flame, is ordained for the ſuſtaining of life and its offices: but truly the Divine Providence, from the very Creation of the World, hath ſeemed to have predeſtinated Forms to natural Bodies, to wit, that they might remain as ſo many Figures or Types, according to which every Portion of matter framing the Concrete, whether animate or inanimate, might be modificated; ſo that the Maſs, according to the virtues of the hidden Seeds, being diſpoſed after this or that manner, happens to have the form of a Stone, a Plant, or Brute, or of any other kind; then the acts and affections, appropriate to ſuch a Species, follow the form it ſelf. When therefore Life or Soul is deſtinated to theſe kind of Functions of the more perfect Animals, for the performing of which, the blood, after the manner of burning Liquors, ought to be perpetually hot, and as it were inkindled; what ſhould hinder, but that the act of Life, or of that corporeal Soul (conſiſting in the motion and agglomeration or heaping together of moſt ſubtil and agil Particles) may be called a certain Burning or perpetual Fire of the bloody Maſs? Wherein although the accidents and chief qualities of common fire are implanted, yet the form of fire is obſcured, as being ſubjugated to a more noble form, *viz.* of the corporeal Soul: not much unlike water, which being congealed into Ice or Snow, lays aſide the ſpecies of water for a time, and may be applied to other uſes far diſtant from fluidity.

But truly, though we affirm, that the corporeal Soul doth ſtick in the Blood, yet we do not, that it is adequated or limited to it: becauſe whilſt the more thick portion of it, as the Roots of ſome Tree, fixed in the Earth, are ſowed in the bloody Maſs, the more noble part of the ſame Soul, as the higher branches, are expanded in the Brain and nervous Syſtem; or as we before hinted, when the vital or flamy part of the Soul is contained in the blood, the animal or lucid portion of it is contained in the Head and its Appendix: by which juſt limit the Sphere of either may be defined, neither may the vital flame impetuouſly break through the animal Region, the ſubſtance of the Brain being more cold, and alſo ſhining or bright, is oppoſed to it, as it were an icy or glaſſie Bar, whoſe inferiour frame or ſubſtance, the ſmall and ſlender as it were rivers of the Blood, for the ſake of cheriſhing heat can enter: but truly ſpirituous Particles plentifully flow from its juice or liquor, every where heaped up near the confines of the Brain, and there diſpoſed as it were to be ſtilled forth, which being immerſed in the Brain, and more exalted, affords matter, out of which the animal Spirits are procreated, to be derived through the Nerves into the various Regions of the Body.

THE

THE SECOND

Phyſical & Medical DISCOURSE.

Of Muſculary Motion.

AS there are two chief or primary Faculties of the Corporeal Soul, to wit, the Senſitive and Motive, we have aſſigned certain exteriour Powers of either of them, which are chiefly acted in the Nervous ſtock, and others interiour, the Exerciſes of which lye within the Brain, to wit, ſuch as the Imagination, Memory, Appetite, &c. What we have publickly diſcourſed of ſome time ſince both concerning internal and external Senſes, may perhaps hereafter be brought to light and made publick: in the mean time, becauſe I am oppoſed, concerning both the natural and convulſive Motion, I think it fit at preſent to publiſh what I had meditated touching the Motive power, and what Hypotheſis I had conceived of ſo hard and highly intricate a thing.

The motive Faculty of the bodily Soul is wont to be exerciſed with another kind of Action than the ſenſitive, *viz.* with a divers aſpect and tendency of animal Spirits. For that every Senſe is a certain paſſion, wherein the Soul, or ſome portion of it, being outwardly ſtruck, is forced to nod or ſhake, and a wavering of the Spirits being inwardly made to look back towards the Head; but on the contrary, every Motion is a certain Action wherein the Soul ſeems to exert it ſelf whole, or part of it ſelf, and by a declination or fluctuation of Spirits being made to bring forth a Syſtaſis, and to extend ſomething as it were its member. Further, whilſt the Soul ſo exerts it ſelf, or ſome part of it ſelf, that the works then deſigned might be performed, an heap of animal Spirits being every where diſpoſed in the motive parts, ſometimes one, ſometimes more are raiſed up by the Soul, which by that means being expanded with a certain force, and as it were exploded, they blow up the containing bodies, and ſo the ſame being increaſed as to their thickneſs, and made ſhort as to their length, are made to attract the adjoyning member, and ſtir up local motion.

1. In every motion, theſe three things ought to be conſidered; *viz.* Firſt, the original of the Action, or the firſt deſignation of the Motion to be performed, which is always in the Brain or Cerebel. Secondly, its inſtinct or tranſmiſſion of the thing begun to the motive parts, which is performed by the commerce of the Spirits lying within the Nerves. Thirdly, the Motive force it ſelf, or exertion of the Spirits implanted in the moving parts, either into a contractive or elaſtick force. From this threefold Fountain, *viz.* as the buſineſs is performed in every one of theſe in a various manner, very many kinds and differences of Motions are deduced.

1. As to the original or beginning of Motion, we ſhall take notice, that that which proceeds from the Brain, with a knowing and auſpicious appetite, may be called Spontaneous or Voluntary; but that which is wont to be excited from the Cerebel, where the Law of Nature reſides, ſuch as are Reſpiration, the Pulſe, with many others, may be called meerly Natural, or Involuntary: either of theſe is either direct, which is ſtirred up of it ſelf, or primarily from this or that beginning, as often as the appetite requires this or that thing, out of a certain proper, and as I may ſay, inteſtine deliberation, and chuſes out reſpective motions; ſo in like manner, when the ordinary offices of the natural and vital Function are performed, according to the ſolemn Rite of Nature; or the motion of either kind is reflected, to wit, which depending on a previous ſenſe more immediately, as an evident cauſe or occaſion, is preſently retorted; ſo a gentle titillation of the Skin cauſes a rubbing of it, and the more intenſe heats of the *Præcordia* ſtir up the Pulſe and Reſpiration.

2. As to the Vehicle of the Inſtinct, which we ſuppoſe to be wholly done by the Nerves, foraſmuch as it is performed by a ſingle Nerve, or by more at once, it is called either a Simple or Complicate Motion; then for that ſome Nerves help motion more or leſs than others by ſooner or later moving. this or that member is ſaid to be moved firſt, or by it ſelf, and another by conſent: yea, and that conſent is wont to be acted or done with neighbouring or more remote parts, and that with a divers reſpect: But we have in another place largely ſhewn inſtances of theſe kind of ſympathetick motions, as alſo the cauſes of each of them, and their manner of being made.

3. There

3. There is another, and that a remarkable diſtinction of Motions, taken from the various conſtitution of the moving parts: to wit, parts endued with nervous Fibres, and in which the motive Spirits dwell; either they are Muſcles, which perform local Motions; or membranaceous bodies, the motions of which are terminated in themſelves, which therefore we call Inteſtine. As to what belongs to local motion, of which only we treat at preſent, although it be confeſſed by all, that the Brain or Cerebel, and the Nerves and Muſcles together one or more, as it were with joynt forces, do contribute to this motion; alſo, though it may be ſufficiently underſtood, that the beginning of the motion to be performed is deſigned in the Brain or Cerebel, and that its inſtinct is conveyed wholly by the Nerves; yet by what means the Muſcles perform that work, far exceeding any mechanick virtue or operation, ſeems moſt hard to be made plain.

That local Motion is performed by traction, and doth depend upon the contraction of a Muſcle, is not only a vulgar Opinion, but is alſo plain by ocular demonſtration; yet it is very much diſputed and variouſly controverted among Authors concerning the manner of Contraction and efficient Cauſe; ſome think it enough to ſay, that the Soul it ſelf, by its preſence, doth actuate the Muſcle, or contract or draw out here and there its Fibres, as it were a net ſpread forth. But indeed this is to attribute to the ſenſitive Soul a ſupernatural, and as it were Divine virtue. To wit, that the ſame, by its meer Spirit, was able to bend and force heavy and very great bodies whether it pleaſes. Further, for what end are the motive Organs framed with wonderful artifice and manifold difference, unleſs that after the manner of Machines, they might perform their operations by an orderly ſtructure, and as it were mechanical proviſion of parts? Truly it will be no hard thing to apply the exerciſes of a Muſcle and of the whole nervous Function, and to explicate them according to the Rules, Canons, and Laws of a Mechanick. Before I enter upon this, I think it not amiſs firſt to ſpeak ſomething of the make, conformation, and uſe of a Muſcle in general. The ancient Anatomiſts, almoſt all with one conſent, did divide the body of a Muſcle into Head, Belly and Tail; taking for the Head the extremity of the Muſcle connexed to the part, to which contraction is made; for the Tail, the end or portion of the Muſcle inſerted to the part to be moved; for the Belly, the part of the Muſcle coming between, which is beheld more turnid, with a bulk of fleſh; then for the performing of motion, they did ſuppoſe the Muſcle to ſwell up about the Head and Belly, and ſo to grow ſhort as to its length, and to attract nearer to it ſelf the hanging part; yet by what means, and for what cauſe the belly of the Muſcle ſwells up, none yet hath clearly unfolded.

Moreover, although the Doctrine of the Nerves hath been much deſcribed by the moſt skilful Anatomiſts of every Age, ſo that the Muſcles of the whole Body, (as it is thought) have been exactly recounted, and offices aſſigned them, and monſtrous names fitted for the expreſſing them, yet the true frame of a Muſcle, not yet ſhewed by others, firſt began to be delivered lately by the moſt ingenious Doctor *Steno*. He hath found out in every Muſcle two oppoſite Tendons, into which both the Fibres go; yea, and hath taught, that the ſame Fibres wholly, which compoſe ſtrictly on one ſide, the Tendon of the knitting being more looſly joyned, do conſtitute the fleſh; yet ſo, that ſome being laid upon others, compoſe the thickneſs or profundity of the Muſcle, and ſome laid nigh to others, its breadth or latitude: he calls the former Fibres *Ordines* or Orders, but the other *Verſus* or Turnings; then the parts and compoſition of a Muſcle being after this manner laid open, he aptly reduces its Figures to Mathematical Rules, and according to Canons thence taken, ſhews the action to be unfolded: becauſe he advertiſing, that in a Muſcle with a ſimple right line, all the fleſhy Fibres, parallel within themſelves, and for the moſt part equal, are carried from one Tendon obliquely into another; and that thoſe Tendons are ſowed in the oppoſite ends or angles of the fleſh, whereby he moſt ingeniouſly deſcribes a Muſcle to be, *a Collection of moving Fibres, ſo framed together, that the middle fleſh conſtitute an oblique angular Parallelopipedum, but the oppoſite Tendons compoſe two quadrangular Priſms or Figures.* The Inſtrument which Painters uſe for the deſcribing many Examples of the ſame thing, fitly repreſents the figure of this delineated in a plain: becauſe the ſtyles being fixed to the oppoſite Angles, expreſs the inſertions of the Tendons and the Parallelogram it ſelf the fleſhy part of the Muſcle: for when the oppoſite Angles are diduced to a great diſtance from one another, and made ſharper, the two ſides come nearer together, and render the *Area* or middle of the Figure longer, but narrower, a Muſcle not contracted is denoted: But if the ſame Angles are brought nearer, and made more obtuſe, the two ſides go farther apart, and ſo make the middle of the Muſcle ſhorter, but alſo wider, a contracted Muſcle ſeems to be repreſented. In the mean time, in either ſite of the aforeſaid *Parallelogram* the quantity or longitude of the ſides is not changed, but only their poſition, and the largeneſs of the Angles is varied: whether it may be alſo ſo in a Muſcle, ſhall hereafter appear. In the mean time, we ſhall take notice, out of the obſervation of the moſt Learned *Steno*, that a Muſcle is either ſimple, which conſiſts of one belly and two Tendons, of which ſort there are many in the Arm and Leg, which are the movers of the fingers and toes, yea and almoſt every where in other parts of the Body; or compounded, that hath many bellies, to every one of which, two oppoſite Tendons are hung; yet ſo, as when thoſe compounded Tendons, to wit, two together, ſhall be joyned, one compound Tendon enters the middle of the fleſh, and the other embraces the middle on both parts. This is evidently diſcerned in the Maſſeter or Throat-muſcle, the Deltoid, and divers others, in all which, even as in a ſimple Muſcle, whilſt the fleſhy Fibres (to which only the motive power belongs) are contracted, the oppoſite Angles are enlarged according to the inſertions of the Tendons, and ſo the bellies being made ſhorter, and at the ſame time thicker, do ſwell up.

In

In a ſimple Muſcle, according as one Tendon or both together, or either by turns, ought to be drawn; beſides, according as the part to be drawn is thin, or broad, or planted near or far off, and for ſeveral other reſpects the fleſhy belly is diverſly formed; and as the *Rhomboides* is its chiefeſt regular figure, yet that alſo is ſometimes triangular, ſometimes trapezial or quadrangular, pyramidal, ſpiral, ſemilunar, or like an Half-moon, or of ſome other irregular form. But in all theſe kind of Muſcles, the fleſhy Fibres, according to all their poſitions, whilſt they are contracted, at the ſame time intumiſie or ſwell up, and are ſhortned from either end towards the middle, though in all Muſcles not always in a like manner and dimenſion; for if either Tendon be to be drawn at once, the contraction from either fleſhy end, is for the moſt part equal; but at the ſame time, if one only be drawn from the others that are immoveable, the contraction is made leſs, and ſometimes, *viz.* where the fleſh immediately ſticks to the bone without any notable Tendon, almoſt none.

The compounded Muſcles are diſtinguiſhed with a far greater variety; for beſides their diverſity of figures, all which would be an immenſe labour to enumerate, according as they are more or leſs compounded, or have their bellies more or fewer, with a manifold Series ſtretched out here and there, with Fibres ſometimes of the ſame, ſometimes of a divers order, they are very much differenced.

The more thin and leſs compounded Muſcle, when perhaps it is ſorted into two or three bellies, diſpoſed in the ſame being plain, hath the ſeries of fleſhy Fibres for the moſt part looking diverſly, all the exteriour Tendons embracing one end of the Muſcle, and hath the others intermediate or that come between immerſed about the other end; ſo that the ſeveral fleſhy Fibres of every Belly lye parallel between the one extreme Tendon and the other intermediate Tendon. The thicker and more compounded Muſcle, that it might perform at once quick, hard, and long motions, hath many bellies planted in divers plains, and the ſeries of fleſhy Fibres (which are all ſhort) looking many ways. The frame of them, although it be very intricate, that one can ſcarce number all the bellies, much leſs obſerve their habitudes, mutual dependences, and means of connexions among themſelves; yet they may in ſome ſort be reduced to this common Rule in moſt, to wit, in the great compounded Muſcles, ſuch as are thoſe round ones which contribute mighty ſtrength and elaſtick force to the middle of the Arms and Legs, we may take notice, in one end of two vaſt exteriour Tendons covering almoſt the whole ſuperficies of the Muſcle, which being divided preſently into many fiſſures or clefts, are ſtretched out between a broad ſhoot or claw to the other extremity of the Muſcle; then on the oppoſite ſide, about this other end, a great Tendon enters the middle of the fleſh, which alſo is cleft or divided preſently into many laps, diſtributed through the whole interiour belly of the Muſcle. And as theſe interiour lamens or laps meeting with the exteriour, and being ſtretched out almoſt to the oppoſite end, look many ways, and have their ſuperficies turning on every ſide, ſome every where are deſtinated to others oppoſite, and are committed or ſent through the intervenient ſeries of the fleſhy Fibres: ſuch a Muſcle, whoſe very many bellies being planted in divers plains, do look many ways, can by no manner or way be cleft or pulled aſunder, but that the other ſeries of fleſhy Fibres muſt be broke aſunder in the midſt. The bellies of a Muſcle, ſo very much compounded, although manifold, yet are very ſlender, ſo that the fleſhy Fibres thereof being moſt ſhort, and having their Angles always equal, but oblique, with the tendinous laps, for that cauſe make a moſt ſtrong attraction. Becauſe the numerous ſeries of fleſhy Fibres ſeem as it were ſo many diſtinct poſts or ſupporters ſet together for the moving of any weight, or rather, for that either great Tendon is preſently ſo cut into many lappets, it is like, as if a mighty draw-rope, hung for the drawing up a body, ſhould be preſently divided into many little ropes or cords, by which many men might draw at once. For whilſt the ſeveral ſeries of the fleſhy Fibres are ſhortned at once, they draw the oppoſite Angles of all the tendinous lappets together, and ſo the belly of the whole Muſcle being intumified or ſwelled up, they ſtrongly draw either end, or that which is moveable towards the middle.

On every Muſcle, both ſimple and compound, there is ſtretched on every ſide a membranaceous covering; beſides, other little Fibres traverſe, to wit, membranaceous, are woven between the direct moving fleſhy Fibres of every one, which clothe each of them, and keep or faſten them together, yea (as it ſeems probable) they both communicate to all the fleſhy Fibres the ſame inſtinct of obeying the motion, and alſo carry to the Tendons, the troops of the inflowing Spirits, received from the Nerve.

The Arteries and Veins, inſerted in the middle of every Muſcle, ſend forth little branches on all ſides, obliquely cutting the moving Fibres, from which leſſer branches diſperſed between the *Interſtitia* of the fleſh, water them all with a flux or reflux of the blood. But the Nerve entring the fleſhy belly of every one, diſtributes ſome ſmaller circles only in the neighbouring parts, as it were bearing only the Symbol or mark of the commanded action, commands the execution of it to the Guard or inferiour Company of the fleſhy Fibres and membranaceous Fibrils.

I had deſigned Figures, almoſt of every kind of Muſcles, to be engraved according to the natural appearances: but the Printer making haſte, I had not the opportunity to diſſect an humane Body, having only taken ſome few Muſcles from the Leg of an Ox, we have cauſed them to be delineated to the life, which are to be ſeen at the end, although the famous *Steno* hath already accurately performed this task. Which Figures, if any one think too much bending to Mathematical Rules, he may with an eaſie labour behold the ſame Conformation of a Muſcle, as he hath deſcribed it in the fleſh it ſelf. For if a ſimple regular Muſcle be cut out of any Animal, and ſo placed, that the Tendons here and there be held on the ſides, the fleſhy Fibres between them intercepted in oblique and equal Angles, be preſſed upon an Horizon-

tal

tal plain, the fleſh will be exactly like a Rhomboides or an oblique angular Parallelopipedum. Then if the ſite of the ſame Muſcle being changed, and its Tendons placed above and below, you ſhall cut long ways the inferior Tendon, and pull the parts one from another, and divide by tearing the whole Muſcle into two parts, you ſhall preſently ſee a moſt elegant ſpectacle, all the fleſhy Fibres diſpoſed in one ſeries, yea and parallel between themſelves, and of the ſame longitude, to proceed from one Tendon into another, and to make both Angles always oblique and equal; although we cannot cleave after this manner the compounded Muſcles, whoſe manifold bellies have a diverſe plain, yet it will eaſily appear, to one curiouſly cutting them, either raw or boiled, two Tendons to be fitted to each Parallelogram of the fleſh.

As to what reſpects the action of a Muſcle, we plainly ſaw in diſſected living Creatures, (which only ſhew this) that it is contracted, yet not ſo as the old Opinion declared, to wit, that the Fibres being contracted from the end towards the beginning, one extremity of the Muſcle was carried towards the other; but the fleſhy Fibres only and their ends are ſeen to be contracted towards the middle, the Tendons being ſtill unchanged and altered neither as to their longitude or thickneſs: which thing alſo the moſt Learned *Steno* did firſt of all obſerve long ſince. This is clearly perceived in the Diaphragma and the Muſcles dedicated for Reſpiration, which are moved with a conſtant change: for as often as the Muſcle is contracted, you may behold all the fleſhy Fibres, in either extremity, to be pulled together at once, and as if they would enter on either ſide one another to be carried nearer, and ſo at once to become ſhorter and thicker, then from that conſtriction to return looſe to their wonted longitude and ſlenderneſs. Whilſt you behold this to be ſo done, you will eaſily think, that ſomething, to wit, ſpirit or ſubtil matter doth flow from the Tendons into the fleſh or fleſhy Fibres, which entring them on either ſide, blows them up, and at the ſame time draws them together nearer within themſelves, that preſently all the Fibres are made ſhorter and intumified; then when that matter recedes from the fleſh or fleſhy Fibres into the Tendons, the Fibres being emptied and looſned from their corrugation or wrinkling, are reſtored to their former longitude, and ſo by turns: whether this in truth be ſo done or no, ſhall be diſcourſed anon.

In the mean time, that we may proceed to other appearances of Muſculary Motion, if that the Membrane of the Muſcle being drawn away, you ſhall ſeparate ſome fleſhy Fibres from others by cutting the little fibrils, whereby they are joyned, and looſen them quite, you will ſee them ſo ſingular and free, to be wrinkled or drawn together in every motion like the others compacted together.

Further, I advertiſe you, that theſe Fibres ſo looſned and freed, ſome cut off in one end, and ſeparated from the Tendon, did yet contract themſelves to the motion of the Muſcle, together with the other Fibres, about the other whole end, without that cut off in the mean time growing flaggy or looſe. After this I divided with a pair of Sciſſers, a certain fleſhy portion of the thinner Muſcle, in three or four pieces tranſverſe, the bigneſs of an inch: which being done, the portions cut off in either end, only entred into, for a ſhort ſpace, ſome light and inordinate corrugations, and preſently became immoveable. The other extreme portions of the Muſcle ſo cut, ſticking to the Tendons, continued to be much more lively and longer contracted, but irregularly and convulſively, to wit, with a certain intortion of the Fibres. Truly, in the Fibres ſo cut off, ſome ſmall footſteps of contraction did remain for a little while, partly by reaſon of the Inſtinct of Motion delivered through the membranaceous fibrils, by which they did yet cohere with the whole fleſh, and partly becauſe the animal Spirits, implanted in the fleſhy Fibres, now divided from the reſt, and left without influence, did exert or put forth their utmoſt contractive endeavours after the uſual manner. For this reaſon ſometimes in the Heart taken out, and in a piece of it cut off with a Sword, as alſo in other Muſcles, after the Nerves and ſanguiferous Veſſels are cut off, a contraction and relaxation continue for ſome time. The other Fibres cut off only by reaſon of the acceſs and receſs of the Spirits from the Tendons were able ſtill in ſome meaſure to be contracted and relaxed.

When in the Diaphragma I had freed many ſingular Fibres from the knittings of others, I tryed what Ligatures put in ſeveral places of them might effect. Some of them then being bound about the middle, were contracted even as the whole fibres, but with ſome little ſwelling about the Ligature. When I had bound others about the ends, where they cohere to the Tendons, now one, then another, the motion was cheifly and almoſt only continued about the free end. Further, in the fibres bound at both ends at once, the contraction wholly ceaſed.

Contraction and Relaxation are not only ſeen, and indeed probable, in the Heart, but in the Diaphragma and other Muſcles appointed for Reſpiration, which uſe to be performed in all, acting viciſſively, according to the Inſtincts of Nature, and for the moſt part equally (though there are not the like intervals of motions in all) yea, and the Muſcles ſerving to the voluntary function, enter oftentimes into ſpontaneous Contractions, unleſs they be hindred by their Antagoniſts, as it appears, for that the Spaſm or Cramp of one Muſcle comes upon the Palſie of another. Contraction and Relaxation are iterated more ſwiftly in the Heart, than in the Muſcles of Reſpiration, and ſo perhaps in theſe, than in ſeveral others. In thoſe ready to dye, the fleſhy Pannicle every where trembling, clearly ſhews their changes by innumerable beatings or leapings.

As to what reſpects the Humors, whereby all the fibres of a Muſcle, *viz.* the fleſhy, tendinous, and membranaceous, and what lies between them, ſeem to be watered, filled, or blown up, we ought to take notice of them, at leaſt two of them, (to wit, the bloody and nervous liquor) if not more. And in the firſt

place it is clearly manifeſt to the ſenſe, that the blood doth waſh all the fleſhy and membranaceous fibres which are interwoven with theſe: becauſe, if the Spirit of Wine, tinctured with Ink, be put into an Artery belonging to any Muſcle, the Vein in the mean time being tyed cloſe, the ſuperficies of all the fleſhy fibres and tranſverſe fibrils are dyed with blackneſs, the Tendons being then ſcarcely at all changed in their colour; it appears from hence, that the blood doth every where outwardly water all the fleſh or fleſhy Fibres, and only thoſe. We have not yet found by any certain mark, whether the blood enters more deeply the fleſhy fibres, or inſtils into them the ſubtil liquor falling from them, although this laſt ſeems moſt probable; but indeed we affirm, that all the fibres, *viz.* the fleſhy, tendinous, and membranaceous, are perpetually and plentifully actuated by the implanted and inflowing animal Spirits, and conſtantly imbued with the nervous liquor, which is the Vehicle of the Spirits. But how far, or how much the aforeſaid humors conduce to the exerciſe of the animal Faculties, doth not eaſily appear; but becauſe the animal Spirits cannot conſiſt without the nervous liquor, and depend very much upon its diſpoſition, we may conclude, that it doth ſerve ſomething to the actuating the motive power; for that reaſon alſo, that the continual afflux of the blood is nevertheleſs neceſſary, an Experiment cited by the Ingenious *Steno*, and proved of late by others, plainly confirms. He hath obſerved, that in a living Dog, the deſcending great Artery being tyed without any previous cutting off, the voluntary motion of all the poſterior parts have ceaſed, as often as he tyed the ſtring, and as often returned again as he looſned the knot.

Theſe are the chief Phænomena to be obſerved concerning the frame and action of a Muſcle in the diſſection of Animals, both of ſuch as were living, as alſo of the dead and dying. From which, however placed together and compared among themſelves, how difficult a thing it is to conſtitute the Ætiology of the animal motive faculty, appears even from hence, that the moſt Ingenious *Steno*, after he had very accurately delivered the Elements of his Myology, by himſelf firſt invented, nevertheleſs he wholly avoided that Hypotheſis which might be founded out of them; for that he yet doubted, whether the explication of a Muſcle by a Rectangle were convenient to the Nature in all, wherefore when many run to the manner of muſculary Contraction, by the repletion of the fibres, and others from their inanition, and ſome to both, he ingenuouſly profeſſes, that the true cauſes of this thing do not clearly appear to him.

And as to this abſtruſe matter, although I do not believe that I am able to bring to light, or ſhew any thing more certainly than others; yet as in mechanical things, when any one would obſerve the motions of a Clock or Engine, he takes the Machine it ſelf to pieces to conſider the ſingular artifice, and doth not doubt but he will learn the cauſes and properties of the Phænomenon, if not all, at leaſt the chief: In like manner, when it is brought before your eyes to behold and conſider the ſtructure and parts of a Muſcle, the conformations of the moving fibres, their geſts and alterations whilſt they are in motion, why is it that we ſhould deſpair to extricate the means or reaſons of the motive function, either by truths or by what is next to truth? Wherefore I think it may be lawful for me here to bring before you our conceptions and notions concerning this thing, indeed notraſhly taken, or to comply with our former Hypotheſis, or to oppoſe any other; which if they ſhall not ſatisfie all, may at leaſt excite others to find out better.

But we ſhall here repeat what we have mentioned before, *viz.* that the power or virtue by which a Muſcle is moved, proceeds from the Brain, is conveyed through the Nerves, and is performed by the fleſhy fibres contracted, and by that means abbreviated. This latter is proved by ocular demonſtration, yea it appears by it, that the motive force doth depend alſo upon thoſe former, and is ſo transferred by a long paſſage, that the influence of the Spirits being ſuppreſſed in their beginning, or intercepted in the way, for that reaſon the execriſe of the deſigned motion may be hindred. Further we notifie, that the motive force is far greater in the Muſcle, or in the end, than in the beginning or middle: becauſe the Brain and depending Nerves are made of a tender and fragil ſubſtance, and can pull or draw nothing ſtrongly; but the Muſcle putting forth ſtrongly its contractive force, ſeems almoſt to be equal to the ſtrength of a Poſt or Crow, or of a Pully or Windlace. Sometimes the local motion is a compound Action to be performed of many Organs, which conſiſt in divers places, and as its virtue is far more ſtrong in the end than in the beginning or way, we will inquire by what means, as it were mechanical, the motive force may be ſo augmented or multiplied in its progreſs, then what is brought to the motion from ſeveral Organs.

As to the firſt, in Artificial things, when for the facilitating of motion, and the increaſing the moving force, many Inſtruments are invented, all of them, or at leaſt the chief, may be reduced to theſe two Heads, *viz.* firſt, either the ſame force or impreſſion may be continued, without the addition of any new force, from one term or end to the other, or from the firſt mover to the thing moved, which notwithſtanding may be much increaſed in the way, as the Centers of Gravity are farther off or multiplied; for the farther the motion is begun from the firſt Center of Gravity, the ſtronger it proceeds, as is beheld in a Crow or Leaver, and in other things reducible to a Leaver. Then if other things be diſpoſed beyond the firſt Center of Gravity ſucceſſively before the end of the motion, as in a circular Wheel, the ſame motive force is wont to be increaſed very much. But to this there is required, that the inſtruments of motion be ſufficiently ſtrong and tenacious in their whole tract; for otherwiſe the motive force being increaſed, the ſame breaking falls down before the deſigned action be performed. Secondly, there is another way of multiplying the motive force to a great degree, and alſo at a great diſtance, which is performed with the addition of new forces or of freſh ſupplies, to wit, when the elaſtick Particles, or thoſe making the force, being diſpoſed and ſhut up in private places, as it were little Cells, afterwards, as occaſion ſerves,

are

are ſent forth by a light contact or blaſt of a remote Agent, into the liberty of motion, which they readily perform. By this means, Air compacted and ſhut up, when it is permitted to get out, impetuouſly forcing a Bullet or other ſubject, ſends or drives it out a great way. It is ſufficiently known what mighty and often horrid forces Gun-powder yields about the end of the Exploſion, when in the beginning or firſt inkindling, the force being tranſmitted through the fiery fume, as yet weak, might be reſtrained by a light impreſſion of the hand. There are alſo other exploſive little bodies of a various kind, which being hid in convenient Boxes or Cells, when they are raiſed up into motion by an inkindling, or irritament, or provocative, do often exert an incredible force. It behoves us then to inquire from which of theſe ways it comes to paſs, that the motive force doth in the Muſcles ſo far exceed the force tranſmitted from the Brain through the Nerves, or whether the action of a Muſcular Motion be merely contractive, or rather elaſtick, or in ſome meaſure exploſive?

Concerning theſe things it manifeſtly appears, that the Muſcles do draw, to wit, being abbreviated, do bring the Tendon with the hanging part towards it ſelf. Further, for as much as there is need for the officers of traction to be ſometimes more ſtrongly, ſometimes more weakly performed by them, ſo to have the Centers of Gravity now higher, now farther off planted from the beginning of the motion; hence the Muſcles which extend or bend the Thigh, eſpecially the *Pſoæ* and *Glutiæ* (great Muſcles beginning in the Breaſt, and reaching into the Thigh) do hide their fleſhy moving fibres deeply within the Trunk of the Body: but thoſe which turn about the Thigh are conſtituted either near the hole or the riſing of the Bone of the Thigh, or ſomewhere thereabout; in like manner it is obſerved in all the reſt of the members, that the belly of the Muſcle gets a more remote or nearer ſite from the article or hinge of motion, as it deſigned for performing either a ſtronger or weaker motion; But truly this doth not hold as to the other moving parts, to wit, the Brain and Nerves, which cooperate with the Muſcles in the motive Act; becauſe, although the motive force is carried by a long paſſage through all theſe Organs, yet it ſeems impoſſible, that a contraction ſo ſtrongly performed by a Muſcle, ſhould be begun by the tender and immoveable Brain, and continued through the ſmall and fragil Nerves, but that it muſt neceſſarily be ſuppoſed ſome motive Particles are hid in the Muſcle, which, as occaſion is given, are ſtirred up according to the Inſtinct, delivered by the Nerves from the Brain, into motion, as it were with a certain exploſion. But what theſe Particles may be, by what means they are inſtigated into motion, and how they induce the contraction of a Muſcle, ſeems moſt difficult to be unfolded.

Truly it may be lawfully concluded from the effect, that elaſtick Particles, and fit to move themſelves, are contained in the Muſcles, and hid every where within the fibres, becauſe the Anatomy of living Creatures diſcovers often a motion in a ſeparated Muſcle, yea in its fibres divided one from another. The Hearts of ſome Animals beat a long while being pulled out of the Body, the Muſcles cut off, ſometimes perform the motions of contraction. In great labouring Beaſts ſlain or dying, although the Heart and the Brain be taken out, the fleſhy Pannicle perfoms for ſome time very many turns of contractions and relaxations. From theſe it is manifeſtly clear, that there are among the Particles of the Muſcles agil and ſelf forcers, or carried by their own force heaped together, which, although the animal œconomy be very much diſturbed or overthrown, do enter into motion of their own accord, yet in a tranquil eſtate they perform no actions, unleſs commanded by the Brain or Cerebel, and delivered by the Nerves.

Whilſt a Muſcle is contracted, the cutting up of a live Creature ſhews only the fleſhy fibres to run into motion by themſelves, to wit, being made more tumid, ſharper, and ſhorter at the ſame time, to amplifie or enlarge the belly of the Muſcle, and in the interim, the Tendons, as if immoveable of themſelves, to wit, not altered either as to their thickneſs or length, only pulled as it were by the fleſhy fibres, to be moved, and to draw with them the moved part; whence it ſeems to be manifeſt, that the animal Spirits or elaſtick Particles, whichſoever they are, whilſt they perform the Muſculary Motion, are only or chiefly agitated among the fleſhy fibres. Further, hence any one may ſtrongly think, that ſuch Particles are not at all contained, or are wholly idle in the tendinous fibres; for as we have noted, that the Tendon is not changed in the act, we may lawfully ſuſpect, that it is only inſtead of a Crook, by which means the fleſhy fibres being contracted, may draw the member to be moved at a diſtance from them towards themſelves.

But indeed it ſufficiently appears by evident ſigns, that the animal Spirits or elaſtick Particles do lodge within the Tendinous fibres, and truly much more plentifully than in the fleſhy: Firſt, the ſenſe ſhews this, to wit, the touch, which is much ſharper and far more ſenſible in the Tendon than in the fleſh: yea any irritation or breach of the unity happening in that part, brings not only a moſt troubleſom ſenſe, to wit, a very cruel pain, but beſides, is wont to excite in the neighbouring fleſh a Tumor or Swelling, and frequently moſt grievous Convulſions; whence we neceſſarily conclude, that the animal Spirits do inhabit the tendinous fibres in great abundance: but what they do there, and by what means they ſerve to the motive function, we will next inquire.

As often as the motion of a living Muſcle was beheld by me, I conſidered and weighed in my mind by what means all the fleſhy fibres were contracted and releaſed by turns, I could conceive or collect no other thing than that in every contraction, the Spirits or certain elaſtick Particles did ruſh into the fleſhy fibres from either Tendon, and did intumifie and force them nearer towards themſelves or together; then the ſame Particles preſently coming back from the fleſh into the Tendons, the relaxation of the Muſcles happened. In a bare or naked Muſcle, when I had ſeparated every fleſhy fibre or a company of them apart

from the reſt in the whole paſſage by help of a Miſcroſcope, I moſt plainly perceive the Tumor, begun at either end of the fleſh, to be carried towards the middle, as it were by the Spirits, entred here and there at once. Further (which I mentioned before) each fibre being tyed about the middle, being as it were as yet free and compacted with the others, was contracted or drawn together; but a Ligature being put to both ends, is remained flaggy conſtantly above or beyond the bound place. But that I might no longer doubt concerning this, I applied two Ligatures, at equal diſtances from the middle and the ends, about the ſame bundle of fleſhy fibres, which being done, a contraction and ſwelling up ariſing preſently from either fleſhy extreme to the places bound, went no farther; the middle part between in the mean time being unmoved, remained flaccid; whence it may be well concluded, that in every muſcular contraction the animal Spirits or elaſtick Particles do leap out from the tendinous fibres into the fleſhy, and viciſſively in the relaxation, recede or run back from theſe into thoſe.

However this being proved and granted, there yet remain very many difficulties concerning Muſcular Motion; for firſt, it may be asked how the animal Spirits, which enter ſilently, or without any incitation, or Tumor, the tendinous fibres do ſo blow up the fleſhy fibres, that they are able to force them altogether into ſhorter ſpaces.

For the producing this effect, plenty of Spirits leaping from the tendinous fibres, do not ſeem alone ſufficient; but beſides, we may ſuppoſe ſome other kind of Particles, implanted in the fleſhy fibres, meeting with the others flowing from the Tendons, do forthwith ſtrive, whence a mutual rarefaction, and turgeſcency or ſwelling up of them, or an inflation or ſudden blowing up of the containing bodies, together with an abbreviation or ſhortning of them, doth ariſe; not much unlike, as when the Corpuſcles or little bodies of fire entring into a piece of leather, or any thing, and forcing variouſly here and there its implanted Particles (whereby they are preſently inſnared) make it ſo to be ſtuffed and wrinkled; in like manner alſo the animal Spirits, although they paſs through the Tendons, where they are ſolitary or by themſelves, without moving them (as the Effluvia's of heat in Metals or more dry bodies) yet being dilated in the fleſh, for that there joyning with elaſtick Particles of another kind, they are expanded or ſtretched out, they cauſe the ſudden inflations and corrugations of the containing fibres. But we have elſewhere ſhewn, that ſuch Particles divers and wholly heterogene to the nature of the Spirits, may be copiouſly and eaſily carried to the Muſcles. For indeed it is plain by ocular demonſtration, that the blood doth every where waſh and water outwardly all the fleſhy fibres, which beſides, it is thought not only to nouriſh, but alſo to be buſied about the offices of the animal Function: and what can be leſs ſuſpected, than that it doth inſtil into their Pipes a certain ſubtil liquor, whoſe Particles being agitated, and alſo rarified by the Spirits flowing therein, ſtuff up the fibres, (as we but now hinted) and compel them intumified, by reaſon of the aſſault on either ſide made, into ſhorter ſpaces.

But that the fleſhy belly of the Muſcle, whilſt it is contracted, doth ſwell up, is not at all to be doubted, becauſe this is evidently beheld by the ſight and touch in the diſſection of living Creatures: to wit, all the fleſhy fibres being wrinkled together, are made more tumid and ſharper, and ſo ſhorten the Muſcle, and make it alſo thicker and broader: For the more certain belief of this, when I had bound ſome of the fleſhy fibres, ſeparated from the knitting of the reſt, and had left others near them looſe, there appeared a notable difference between thoſe flaccid or not ſwelled, and theſe intumified or ſwelled up in every contraction of the Muſcle.

But if it be demanded, of what nature, to wit, whether ſpirituous ſaline, as may be believed, or of any other diſpoſition, the animal Spirits, derived from the Brain into the Muſcles, may be; and then whether the other Latex, immediately carried to them from the blood, is ſulphureous or nitrous. Concerning theſe, becauſe it appears not to the ſenſe, we ſhall pronounce nothing raſhly or poſitively. But even as in other natural things, the active Particles of a various kind, which being unlike among themſelves, are found apt mutually to grow hot, or to be ſtruck off from one another, otherwiſe to be rarified or expanded; and as the inteſtine motions of Bodies, and eſpecially the elaſtick, ſuch as are the contractions of the Muſcles, can only proceed from the congreſſions of ſuch like, certainly it may be lawful to preſume, that theſe do wholly depend upon ſuch a cauſe.

Therefore as to the Muſculary Motion in general, we ſhall conclude after this manner, with a ſufficiently probable conjecture, *viz.* that the animal Spirits being brought from the Head by the paſſage of the Nerves to every Muſcle, (and as it is very likely) received from the membranaceous fibrils, are carried by their paſſage into the tendinous fibres, and there they are plentifully laid up as in fit Store-houſes; which Spirits, as they are naturally nimble and elaſtick, where ever they may, and are permitted, expanding themſelves, leap into the fleſhy fibres; then the force being finiſhed, preſently ſinking down, they ſlide back into the Tendons, and ſo viciſſively. But whilſt the ſame animal Spirits, at the inſtinct given for the performing of motion, do leap out of the tendinous fibres into the fleſhy, they meet there with active Particles of another nature, ſupplied from the blood, and preſently they grow mutually hot; ſo that by the ſtrife and agitation of both, the fleſhy fibres, for that they are lax and porous, are ſtuffed up and driven into wrinklings, from all which being at once wrinkled or ſhrivell'd up, the contraction of the whole Muſcle proceeds; the contraction being finiſhed, the ſincere or clear Spirits, which reſide or are aſſwaged, go back for the moſt part into the tendinous fibres, the other Particles being left within the fleſh; the loſs or waſting of theſe the blood ſupplies, as the Nerves do thoſe. By what inſtinct the muſcular contraction begins and ends, ſhall be inquired into preſently.

That

That the animal Spirits, flowing from the tendinous Fibres, may enter equally all the fleſhy, there are two Tendons in every ſimple Muſcle, which are ſo conſtituted, according to oppoſite Angles, that the Spirits running to them from a twofold ſtarting place or bound, might preſently fill the whole belly of the Muſcle, and that motion being finiſhed, might immediately ſwiftly retire. If the contraction ought to be performed indifferently towards the middle of the fleſh, the Tendons for the moſt part are equal; but if the motion inclines more towards one region of the fleſh, one Tendon (to wit, which may ſupply a greater company of Spirits) exceeds the other in magnitude. If the Muſcle, whereby it may be the ſtronger, is big and endued with an ample bulk or ſubſtance, it is divided as it were into many Lobes or Bellies, and two Tendons are ordained to each of them; to wit, to the end that the animal Spirits might be carried through ſhort paſſages from the Tendons into the fleſhy fibres, and might leap back again: becauſe the compounded Muſcle doth not always contain more ſeries of moving fibres, that it might perform many and divers motions, but that it might make the ſame motion often with the greater ſtrength. For, as we hinted before, as a ſimple Muſcle was as a ſingle leaver or bar, the compound ſeems as if it were many leavers or bars ſerving for the removing the ſame body conjunctly.

Further, hence we may obſerve in ſome Muſcles, which are ſimple and regular, that all the fleſhy fibres are equal, and ſo all the tendinous of one extreme being put together, are equal to all of the other end being put together; yet they ſingle, where they are ſhorter in one Tendon, are longer in the other, and ſo diſpoſed, that the tendinous fibres on either part, the top and bottom, have their exceſſes inverſe, and at once equal; to wit, that here a long is laid upon a ſhort, or the longeſt upon the ſhorteſt, and there quite contrary, the ſhorteſt upon the longeſt, to the end, that the motion might be ſo made every where in this or that ſide of the Muſcle, or at the end more ſtrong, more plentiful Spirits flow together into thoſe parts from the longer tendinous fibres, and on the contrary: wherefore in ſome Muſcles leſs neceſſary, where the part of the fleſh growing to the bone, either becomes immoveable, or only ſerves for the filling up of empty ſpaces, one Tendon is ſhorter or leſſer, and oftentimes degenerates into a bony or cartilaginous hardneſs. Further it is obſerved, as to other ſtrong and greatly moving Muſcles, that their Tendons are not ſo diſpoſed, as if they were only ſtays, props, handles, or hanging crooks of the fleſhy fibres; for ſo they are only conſtituted in their extreme ends; yet the tendinous fibres, that they may be made more apt promptuaries of the animal Spirits, being ſtretched out almoſt into all parts of the Muſcle, receive every where both ends of the fleſhy; which indeed yet more manifeſtly appears in the compound Muſcles, for that one Tendon being compounded, embraces the extreme fleſh, and the other enters into the middle of the fleſh, as hath been already ſhewn.

But truly they animal Spirits, whilſt they leap out of the tendinous into the fleſhy fibres, are not ſufficient of themſelves for the wrinkling of them, but require another elaſtick Copula from the blood; this may be argued from many reaſons. Firſt, it ſeems to appear from this, that the ſame Spirits being ſolitary or by themſelves, though moſt thickly planted within the Tendons, ſtir up no Tumor or Contraction whilſt they are moved in them; wherefore being dilated within the fleſhy fibres in a leſſer quantity, and having got a larger ſpace, they would be ſtretched out, unleſs they met or ſtrove with other Particles, much leſs would they obtain a contractive force. Beſides, when any wound or grievous trouble happens to a Tendon, the belly of the Muſcle or fleſhy part is chiefly troubled with a Tumor or Spaſm; for the Spirits being irritated, not ſo much within themſelves, but where they are violently driven among heterogene Particles, ſtir up the greateſt tumults and inordinations. But further, when the fleſhy fibres are watered with the ſanguineous humor beyond other parts, and more than may ſuffice for their nouriſhment, for what other uſe ſhould it be aſſigned, unleſs that it may contribute to the motive function? Eſpecially we take notice in lean Bodies, which are more ſparingly nouriſhed, that the Muſcles being fuſed or drenched with more plentiful blood, do perform the ſtrongeſt endeavours of motions: moreover, it doth not appear by what way beſides, the expence of the Spirits in a Muſcle, conſumed with continual hard motions or labours, ſhould be made up or renewed, unleſs, beſides the ſmall ſupplements by the Nerves, others ſufficiently plentiful ſhould be ſupplied from the bloody maſs. Add to theſe, that members deſtitute of the wonted afflux of blood, eaſily fall into weakneſs or a Palſie; and that from the obſervation of Doctor *Steno*, in a live Dog the trunk of the deſcending Artery being tyed, all the lower or poſterior members were ſuddenly deprived of motion. And though it doth not yet appear plainly to me, whether the excluſion of the blood from the ſpinal Marrow, or from the Muſcles themſelves, or from both together, be the cauſe; yet however it comes almoſt to the ſame thing, for as much as the animal Spirits being procreated within the Head, and ſtretched out by the medullary and nervous Appendices into every member, without the concourſe of the blood, they ſhould not be able to perform the loco-motive power.

Having thus far explained by what means a Muſcle being contracted in the fleſhy part, as to all the fibres at once, performs the motive function; we ſhall next inquire, what is the reaſon of the Inſtinct whereby every motion, both regular and irregular, is wont to be obeyed or is performed. Concerning this in general, it firſt appears, that the motions of every regular motion, yea and the impulſes of ſome irregular motions being conceived within the Brain or Cerebel, are tranſmitted from thence by the Nerves to every Muſcle. This (as we have elſewhere ſhewn) is moſt evidently declared by the effects and conſequences: yet here great difficulties remain, to wit, how by the ſame paſſages freſh forces of animal Spirits are conveyed form the Head to every Muſcle, and at the ſame time the old ones exerciſing the Empire of the Soul; beſides, with what difference and divers carriage of the inflowing Spirits, the Nerves perform either of theſe tasks, or both theſe offices.

Of

Of theſe, as I conjecture, it ſeems that the animal Spirits, which flowing continually from the Head to refreſh the forces of the implanted Spirits, are carried to the Muſcle by the Nerves, do move to it quietly and eaſily, and being there preſently received by the membranaceous Fibres, they go apart into the Tendons: which kind of relief, although it ſhould be but little in bulk, yet becauſe it is carried night and day by a conſtant courſe, it eaſily ariſes to a ſufficient proviſion for the continual filling up of the Tendons. But that we ſuppoſe, the Spirits ſo brought perpetually to the Muſcle to be transferred by the membranaceous Fibres, and not by the fleſhy, to the Tendons, the reaſon is, becauſe if they ſhould firſt enter into theſe, ſtraight runing into an elaſtick Copula, they would ſtir up the Muſcle into continual motions: moreover, for that in the Heart and Muſcles of Reſpiration the fleſhy Fibres are exerciſed with a perpetual motion, they wait not for the paſſage of freſh Spirits to the Tendons.

But as to what reſpects the Inſtincts delivered through the Nerves from the Head for the performing, or ſtaying, or any ways, altering of the muſculary motion, of theſe we ought firſt to conſider, that the moving animal Spirits, whoſe companies or throngs conſtitute the Hypoſtaſis of the bodily Soul, have theſe two properties as it were implanted in their nature; to wit, that whilſt they are lively, numerous, and free, they exert or expand themſelves, then that force being finiſhed, they being a little diminiſhed, retire themſelves and grow quiet; but afterwards being refreſhed, they leap out again, and ſo viciſſively. Waking and ſleeping, and the alterations of work and idleneſs or reſt, inbred in all living Creatures, ſufficiently declare this. Wherefore to the impulſe or inſtincts of ſome Muſcles, (which are wont to be perpetually contracted and releaſed) ſcarce any thing more is required, but that their Tendons may be ſupplied by the Nerves with a conſtant influx of animal Spirits; but the Spirits themſelves, becauſe they are numerous and expeditious of their own nature, do willingly leap out into the moving Fibres, then the charge being performed, after a ſmall loſs or expence, they immediatly withdraw, and being again preſently recruited, they are again expanded, and ſo viciſſively. Further, their actions (which chiefly are Pulſe and Breathing) are variouſly changed according to the degrees of heat or of the affections; for as much as the Spirits being brought by the Nerves, are ſent from the Cerebel, ſometimes more remiſſly, ſometimes more plentifully, or more nimbly.

Further, in ſome other Muſcles ſubject to the Empire of the Appetite, as the animal Spirits naturally affect turns of expanſion and receſs, there is only need of a ſign to be given, either for the performing or ſtopping of the commanded motion; either of which, the inflowing Spirits by their various knocking againſt the Muſcle, eaſily perform, in ordering the implanted Spirits into various aſpects or tendencies. When the Muſcle is contracted, the implanted Spirits, whilſt they are looſned from either end towards the middle, look and tend with a changed front from the middle towards either end. And ſo, whilſt the inflowing Spirits carry the Symbol of performing Contraction, they being incited by heaps within the Nerve, more fully blow up its end, inſerted to the Muſcle, (where they are more thickly crowded together) and ſo cauſe it there to be contracted and abbreviated; whereby it comes to paſs, that the ſame inflowing Spirits, about to enter into Muſcle, are at that time ſtopped by a mere heap, or rather are called back towards the intumified Nerve; wherefore by and by the whole ſeries of the implanted Spirits (hence their inclination being changed) alſo looks that way, and ſo the inhabitants of the Tendons, leaping out from their little Cells into the fleſhy Fibres, cauſe motive contraction: then the motion is broken off or ceaſes as ſoon as the Spirits being before called back towards the Nerve, do tend again into the Muſcle, and ſo the front of the Army being again changed, bands of the implanted Spirits are preſently compelled into the Tendons. That the thing is in a manner thus, I am perſwaded, not out of a mere agreeableneſs or concinnity of our Hypotheſis, but from Anatomical obſervation, Becauſe once diſſecting a Whelp alive, when by chance I beheld ſome Muſcles of the hinder part of the Head and Neck divided and ſeparated at the ſame inſtant, wherein the fleſhy Fibres, as alſo the Nerves inſerted into them, were ſeen at once to be contracted, and being intumified, to be abbreviated.

For the promoting the receſs of the Spirits out of the fleſhy Fibres into the Tendons, whilſt the Muſcle is contracted, the membranaceous Fibrils, which every where cut croſs wiſe the fleſhy, and thickly ſtick between, ſeem to help. The texture of theſe never to be enough admired, is better perceived in a Muſcle endued with large Fibres, *viz.* an Oxes being boiled to a tenderneſs. For in ſuch a one, if gently opening the fleſhy Fibres, you ſhall draw them one from another through the whole ſeries, you ſhall ſee little Fibrils, like hairs, moſt thickly extended upon every one of thoſe Tubes, which little Fibrils not only cloſe and knit together the fleſhy Fibres, but alſo lying upon every one of their ſeries, and cutting them in oblique Angles, they alſo are all carried parallel, from Tendon to Tendon, in an oppoſite ſite to the fleſhy: therefore whilſt the Muſcle being contracted, the fleſhy Fibres do ſwell up, the Fibrils embracing them, that they may give place, are ſomewhat diſtended; then as ſoon as the ſwelling up remits, theſe returning to their wonted ſtraitneſs, preſs together every where the fleſh, and the Spirits being expulſed on either ſide, they reduce them to their priſtine length. It makes for this, that whilſt the Muſcle is contracted, the Spirits inflowing through the Nerves, depart from their membranaceous Fibrils; wherefore theſe being empty and lax, are able more eaſily to be diſtended; but whilſt the Muſcle is relaxed, the Spirits again entring the Fibrils, fill them, and that they may the better bind the fleſhy Fibres, they make them ſhorter.

The Inſtincts of Motions, to be obeyed by the Muſcles, ſo delivered by the Nerves, are, being ſent either from the Brain, performed at the command, and with the knowledge of the Appetite; or from the Cerebel, according to the Laws of Nature, for the moſt part unknown to us. But beſides, ſometimes the Muſcles are carried beyond, or contrary to the pleaſure of the Appetite or Nature, into irregular motions, *viz.* violent and convulſive, and that happens after various manners and for divers cauſes. Concerning theſe, ſome time ſince diſcourſing more largely, we have ſhewn, that from thence do ariſe many kinds and differences of convulſive motions; as the Spaſmodick matter being ſomewhere fixed, doth ſubſiſt either about the beginnings, middle, or ends of the Nerves; or becauſe the ſame thing being wandring and looſe, runs about here and there through the whole paſſages of the Nerves, and ſo variouſly transfers from place to place convulſive diſtempers. But beſides theſe divers kinds of Convulſions, which are excited by reaſon of ſome evil or vice ſticking ſomewhere to the Nerves themſelves, this our Myology or Doctrine of the Muſcles, hath diſcovered ſome convulſions of another kind ariſing from the Muſcles being chiefly affected.

For indeed we muſt advertiſe you, that the animal Spirits, diſpoſed among the Muſcles themſelves, by reaſon of a taint or evil derived from the Brain, or from the Blood, or perhaps oftentimes from both together, are infected with certain heterogene Particles, by reaſon of which they cannot reſt or lye quiet in their Cells; but being always unquiet and reſtleſs, leap out of their own accord from the tendinous Fibres into the fleſhy, and ſo oftentimes produce frequent and cruel Convulſions. But this we have obſerved to be done after a twofold manner, *viz.* firſt, for that the Spirits being burdened with an elaſtick Copula, remain not long within the Tendons, but leaping out from thence into the fleſhy Fibres, induce frequent Convulſions of a Muſcle, but ſhort, and as it were by leaps; or ſecondly, becauſe the animal Spirits, although they ſometimes lye quietly within the Tendons, yet being inordinately ſnatched into the fleſh, and there cruelly exploded, they cannot be preſently repreſſed, brought into order, or reduced into the Tendons, but whether we will or not, they perſiſt a long while expanded, and ſo bring forth a long and very painful contraction of the Muſcle, Which kind of Spaſm, ſufficiently known, we vulgarly term the Cramp.

The former diſtemper (called the Convulſive Leaping) is familiar both to malignant Fevers, and to the Scurvy. As to thoſe, we have ordinarily known, when either no Criſis, or an evil one is obtained, that heterogene Particles from the Blood and nervous juyce very much vitiated, are not only laid up in the Bowels, (whoſe diſpoſitions and functions they pervert) but almoſt every where in the Muſcles; and there growing to the Spirits, do affect them with a certain madneſs, ſo as they cannot continue peaceably together, or reſt within the Tendons, but being divided and diſtracted one from another, leap out from thence by bands into the fleſh, and there ſtir up the leſſer and moſt frequent Spaſms or Convulſions. In like manner, by reaſon of the Spirits inhabiting the Muſcles being burdened with an elaſtick Copula there growing to them, ſome labouring with an inveterate Scurvy, cannot contain their limbs in the ſame ſite or poſition, but are neceſſitated ſometimes to extend the hands or feet, ſometimes to fling them about here and there, to transfer them variouſly, and ſometimes to ſubdue their madneſs by running, leaping, or other hard labours.

Treating ſome time ſince of Convulſive Motions, we did almoſt wholly omit the Ætiology of the continuing Spaſm or Tetaniſm, as a thing which depended upon the Doctrine of the Muſcles, to be treated of afterwards: Then we only hinted, that the contraction of that kind did ariſe in one Muſcle, becauſe its other Antagoniſt was reſolved or looſned, which indeed oftentimes happens in the face and ſome members; in which, whilſt the parts upon one ſide are troubled with the Palſie, thoſe oppoſite on the other, as it were looſned in the Reins, are too much contracted. Notwithſtanding, this kind of Spaſm for the moſt part is without pain; beſides, this is not eaſily or preſently paſſed over or cured no more than the Palſie, which is the cauſe of it.

Therefore as to what belongs to the formal reaſon of the Spaſm, called in our Idiom the Cramp; every one labouring with this diſtemper, perceives in himſelf one or more Muſcles to be moſt ſtrongly and involuntarily drawn together, and they being for ſome time ſo highly diſtended, remain as it were ſtiff; and in the mean time, for that the fleſhy Fibres being cruelly contracted, do voilently haul or pull either Tendon, to wit, that which is fixed to the immoveable part, perhaps no leſs than the other part to be moved, they cauſe a moſt troubleſom pain. But ſometimes this Spaſm being excited, by reaſon of the animal Spirits carrying themſelves out impetuouſly into the fleſhy Fibres, doth not ceaſe until the ſame Spirits being returned into the Tendons, ſuffer the fleſh to be relaxed; therefore its neareſt cauſes will be both the greater impetuoſity of the animal Spirits among the fleſhy Fibres, with which they leap thither unbid; and alſo their long continuance or ſtay, for that they return back more ſlowly and difficultly into the Tendons. For the ſecondary cauſes may be reckoned, both the evil diſpoſition of the animal Spirits, and alſo the evil conformation of the Tendons, *viz.* ſometimes this, ſometimes that, and not ſeldom both together.

As to the former; this diſtemper, as other Convulſions, ſeems to ariſe, for as much as the animal Spirits, being burdened with heterogeneous Particles or an elaſtick Copula, at length being irritated, they are incited to the ſtriking of it off: which notwithſtanding, being thick and viſcous, and for that cauſe more tenacious, is not ſoon nor eaſily ſhaken off, but that the Spirits being ſtill provoked by the ſame, and ſhut up within the fleſhy Fibres, are longer detained in the expanſion: which thing perhaps happens not ſo much unlike, as when water and air being joyned together, make a bubble; which, if it be made of water, wherein a little Sope is put, is more tenacious, much more large, and continues longer than that made

made only of mere water. So we obſerve, that they who abound in thick and tartareous humors, are moſt obnoxious to theſe kind of Cramps, and beſides, that they who preſently ſleep upon drinking or eating groſs meats, after full eating, and eſpecially after a large and plentiful ſupper, do ſuffer moſt cruel aſſaults of this diſeaſe; but ſometimes the Tendons themſelves are found to be in the fault, for that they being too hard bound together or obſtructed, they do not eaſily admit the Spirits returning from the fleſhy Fibres. The obſtruction of the Tendons is the cauſe, the Gouty and Scorbutick people, whoſe Tendons ſalt and tartareous humors eaſily run into and obſtruct, are wont to be cruelly tormented with theſe kind of painful Cramps: But that the conſtriction of the Tendons doth ſometimes bring forth this diſeaſe, appears by this, for that ſome Women with Child, (as I have been often told) about the latter end of their Time, by reaſon of the Muſcles of the Abdomen being too much extended, are wont to be troubled with frequent Cramps only in the bottom of their Bellies. For the illuſtrating of this Pathology we will add this following Caſe

A Noble Woman, young and fair, ſome time ſince obnoxious to Hyſterick diſtempers, and now above two years ago to Convulſive, and in a manner Epileptical; of late, by reaſon of the frequent and moſt cruel aſſaults of the diſeaſe, ſhe became alſo Cachectical and Paralytical, that at length her Abdomen was diſtempered with an Aſcites, and her Legs with a wateriſh Tumor, and laſtly, all her lower parts, below her Hips, were deprived of motion; hence, as often as the Convulſive fits infeſted her, ſhe was wont, not now to move her body or members here and there, but ſometimes theſe, ſometimes thoſe parts being ſnatched with the Tetaniſm, were variouſly bent and twiſted about, that in the mean time, ſhe her ſelf ſitting in her Bed or Chair, remained ſtiff and almoſt immoveable. It is not long ſince, that ſeeing the whole manner of one of theſe Fits, I obſerved, not without great admiration, divers ſorts of turns and changes of alterations of the Spaſms. At the firſt aſſault, her eyes being turned about ſwiftly hither and thither, ſhe was preſently taken with inſenſibility, then by and by her head being turned and contracted of one ſide, preſently her arms and legs at once became ſtiff, and all her Joynts, ſometimes of one ſide, ſometimes of both, were bowed or ſtretched out: perhaps after four or five minutes theſe Spaſms both in her Head and Limbs remitting, of a ſudden others, for the moſt part oppoſite, followed; which being often finiſhed in the like ſpace, others far different did ariſe, and ſo for two or three hours, longer Spaſms almoſt of every kind and faſhion, being excited through her whole Body, followed upon one another; ſo that her head being convulſed or pulled by turns from the right to the left, and contracted before and behind, yea and all her Limbs being bent inwardly here and there, or diſtended outwardly in the courſe of one Fit, ſhe exhibited all ſorts of Convulſive geſtures. When at any time the Spaſms of one ſort continued longer in the Head or Limbs than uſual, it was the cuſtom of the Servants about her to blow up ſtrongly into her Noſtrils the Fume of Tobacco; which being done, as the Spirits recovered within, the preſent Spaſms immediately remitted, but upon them others of a new kind ſucceeded. Of late the Legs of this Lady were ſo debilitated by being looſned, that ſhe could neither go nor ſtand, yea her Tendons under either Ham, being made tumid and ſhorter, were ſo contracted, that ſhe could not ſtretch out her Legs ſtraight.

Concerning the caſe of this ſick Noble Lady, it may be demanded, wherefore upon the firſt coming of the Fit, no throwing about of the Body or Limbs, as is wont in moſt Convulſive or Epileptical people, but only continued Spaſms or Convulſions variouſly tranſlated from one part to another, and ſo others, did ariſe? For the ſolution of this, we ſay, that the Spaſmodick matter is not only heaped up in the Brain and Nerves, but alſo in the Muſcles themſelves, and grows to the Spirits inhabiting the Tendons: And as that matter is tenacious, and the Spirits weak, and unable for the ſtriking off quickly or eaſily ſuch a Copula; therefore as often as theſe being irritated, do leap out of the Tendons into the fleſh, the Muſcles being firſt poſſeſt, they cauſe ſtrong and long Contractions; in the mean time, other Muſcles, eſpecially their Antagoniſts or oppoſites, being hindred and bound up from motion, until the Convulſions of the former are remitted; hence the Members, however convulſed, are not moved out of their place, becauſe the moving or carrying of the Body, or any Members, is not performed but by the help or duty of many Muſcles, whilſt ſome of them either rightly cooperate with others, or at leaſt obey them, to wit, ſo that ſome reſpective Muſcles, obſerving due cooperation, are contracted at once, then thoſe being looſned, the contraction of others immediately ſucceeds. But if they which are unequal and unlike, are at once, contracted and ſtrongly convulſed, and ſo continue long, ſo that other Muſcles in the mean time cannot be contracted, there will be a neceſſity for the members bent or extended here and there, to remain as they are wholly ſtiff. But that the preſent Convulſions were always remitted by the blowing the ſmoke of Tobaco up her Noſe, the reaſon is, becauſe the region or ſome part of the bodily Soul being vehemently affected, if by chance a new paſſion equally violent be brought upon another part, the firſt is preſently aboliſhed or ceaſes: For in truth, it appears by conſtant obſervation, where-ever the greater or freſher trouble is, that thither greater plenty of Spirits preſently flock and make a tumult: wherefore any new irritation being excited in the Brain or its Meninges, whatſoever others were begun outwardly among the Muſcles, immediately vaniſh or are obſcured; then as ſoon as this freſh trouble is paſſed over, Convulſions outwardly ariſe forthwith again, but in other parts where more heaps of Spaſmodick matter lye not yet conſumed. But that long continued Spaſms do ariſe, either by reaſon of the Spirits being burdened with a more tenacious Copula, or by reaſon of the Tendons being obſtructed with a viſcous or tartareous matter from either or both, it appears from hence, becauſe this diſeaſe increaſing (as in the caſe of this Noble Lady) the Tendons are at length ſo ſhortned by the more plentiful heaping up of the morbifick matter, that they become

come ſtiff and ſhorter, and for that reaſon they hardly or not at all grant any place to the Spirits for the conſtant performing of the motive function.

Thus much for the Muſculary Motion, both natural and convulſive, and the reaſons of both, which we have proved with what diligence we are able, and by Anatomical Experiments: But if any one ſhall object, that they are not very firm, becauſe we have noted in the cutting up of live Creatures, that the Heart and Muſcles of Reſpiration and the fleſhy Pannicle, after that the Nerves and Arteries are cut away, do continue for ſome time their turns of Contraction and Relaxation, whence it is argued, againſt our Hypotheſis, that their motions do not depend upon the conſtant influx of the blood and animal Spirits; it will be plain to return this Anſwer, That in thoſe about to dye, it ſometimes happens ſo, becauſe the Soul being then diſtracted and drawing near to diſſolution, all the implanted Spirits at once being cut off from the commerce of thoſe influencing or flowing in, do of their own accord exert themſelves, and perform (as long as they are able) their wonted motions; which being continued for a little ſpace only, need not the ſubſidy or aſſiſtance of freſh forces, becauſe the veterane, till they are quite worn out, perform their wonted tasks; yea alſo the old ſanguineous Copula, till it be wholly conſumed, receives and lets go their embraces with a conſtant change; But this more rarely ſucceeds in other Muſcles ſubject to the Empire of the Appetite, and wont only to be exerciſed as occaſion ſerved.

Moreover, as we have affirmed, that the Inſtinct for the performing of Motions is brought altogether through the Nerves from the Head to the Muſcle, and as every Trunk of the ſame Nerve, being oftentimes broken into many ſhoots, variouſly diſtributing them, ſends it to many deſtinated Muſcles, it may very well be doubted, how the animal Spirits, conveying the Symbol of the motion to be performed with a certain choice, do actuate only theſe or thoſe branches apart from other branches of the ſame, and do not indifferently enter all the branches or ſhoots of the ſame; to wit, as the blood paſſes through the Trunk of the Artery, and all its ramifications equally. The moſt Learned *Regius*, that he might ſolve this knot, ſuppoſes in the Nerves ſome little doors, like to thoſe which are found in muſical Organs, the apertures whereof admit the Spirits to theſe or thoſe parts eſpecially, the reſt being ſhut up. But he ought to have ſhewn, if not the little doors themſelves, yet at leaſt by what inſtinct and by whoſe direction ſometimes theſe, ſometimes thoſe are locked up, and others opened. But in truth, this may rather be ſaid, that all the ſhoots of the Nerves and leſſer branches remain diſtinct and ſingular among themſelves from the parts to which they are inſerted, even to their beginnings; ſo that a peculiar tract of the Spirits or way of paſſage lyes open from the Brain and its medullary Appendix, to every Muſcle and nervous part; for in truth, although the Nerves, according to their beginnings, may ſeem to ariſe from the greater Trunks; yet it will eaſily appear, if you ſhall open the trunk and thoſe branches, that in them many little Nerves, only like hairs, for the ſake of a better conduct, are collected together in the ſame bundle; yea, the coverings being ſeparated, you may follow oftentimes the little Nervulets, and thoſe ſingle to the reſpective parts and members, to which they are deſtinated.

But in the mean time, although there be ſingular paſſages or chanels of the animal Spirits of moſt Nerves, diſtinct among themſelves; yet ſome do variouſly communicate with others through the branches and ſhoots ſent on either ſide; which indeed ought to be ſo made, that when many Nerves together, are required to ſome motion of a Muſcle equally, all theſe, by reaſon of the commerce mutually had between themſelves, might conſpire in the ſame action, hence, in ſome motions of the members, as in the ſtriking of a Harp or Lute and other complicated actions, many Muſcles cooperate with admirable celerity; ſo that, although many be imployed at once, they perform their task ſeverally without any confuſion. Beſides, there is need for the Nerves to communicate mutually among themſelves, becauſe of the Sympathetical motions of the members and of ſome of the parts, for neither for any other cauſe is the Nerve of the Diaphragma inſerted into the brachial branches, or thoſe belonging to the Arms, than that the exerciſe of living Creatures, eſpecially in running or flying, might be proportionate to the tenour of Reſpiration. Hence it alſo proceeds, that in any paſſion, the Præcordia being bound up or dilated, the countenance and aſpect of the face, yea and the geſtures of the hands and members are pathetically figured. We have propoſed ſufficient Inſtances of this ſort in our particular Hiſtory of the Nerves, ſo that we need not here add any thing more.

What remains for the illuſtrating our Myology or Tract of the Muſcles, we have taken care to have added, *viz.* four Figures, which may repreſent to the life both the exteriour and interiour true and natural faces or appearances both of a ſimple and compounded Muſcle.

The Explication of the Figures.

The First Figure

Shews a ſimple regular Muſcle, deſcribed according to its natural appearance, in the Belly of which the fleſhy Fibres being opened, are diduced one from another, that the membranaceous Fibrils may be the better beheld.

A. *The right Tendon.*

B. *The left oppoſite Tendon.*

C. *The fleſhy Belly; all the fleſhy Fibres of which lye one by another equal and parallel, but in even and oblique Angles between either Tendon.*

D. *The aperture of the fleſhy Fibres, which being drawn aſide, the membranaceous Fibrils, thickly croſſing them, appear.*

The Secod Figure

Shews a ſimple Muſcle cleft in the middle, after the Tendon being cut off, and portions of it pulled away, that the interiour ſeries of the fleſhy Fibres, or their commixtures or mingling with the Tendons, may appear.

AA. *The right Tendon being placed above, both portions of which divided, do in ſome meaſure appear.*

BB. *The left oppoſite Tendon placed below, either portions of which divided, lye hid for the moſt part under the Fleſh, thoſe towards the edges being only conſpicuous.*

CD. *Portions of the fleſhy Belly divided and ſeparated, which before (this being laid upon that) did cohere, in either of which all the fleſhy Fibres proceed equally, and in like manner obliquely from one Tendon to another.*

E. *Some membranaceous Fibrils repreſented, thickly croſſing the fleſhy Fibres.*

The Third Figure.

Exhibits a certain Muſcle leſs compounded, to whoſe two fleſhy Bellies two compounded Tendons alſo (equal to four ſimple ones) are deſtinated.

A. *The exteriour compounded Tendon, embracing either ſide of the fleſhy Fibres, which being almoſt only conſpicuous on the edges, lies hid for the moſt part under the Fleſh.*

B. *The interiour compounded Tendon, entring into the middle of the Fleſh, which receives on both ſides the fleſhy Fibres, ſent from either ſide of the exteriour Tendon.*

C. *The firſt Belly of the fleſhy Fibres, all whoſe equal and parallel Fibres lye between the oppoſite ſides of the Tendons in oblique Angles and equal.*

D. *The ſecond Belly of the fleſhy Fibres, all whoſe Fibres being in like manner formed, are beheld in the ſame as in the other Belly.*

EE. *Both extremities of the exteriour compounded Tendon.*

F. *The extremity or end of the interiour compounded Tendon, the like to the other being oppoſite, at an equal diſtance from the end of the Muſcle.*

The Fourth Figure.

Shews a regular compounded Muſcle, divided and opened in the middle, ſo that the interiour face of either Belly may appear.

A. *The exteriour compounded Tendon cleft into four parts.*

BB. *Portions of one ſide of the divided Tendon ſeparated from the other.*

C. *Portions near fited, of the other ſide of the divided Tendon, which for the greateſt part lye hid under the fleſh.*

DD. *The fleſh of one Belly alſo divided, and ſeparated one far from another.*

EE. *The fleſh of the other Belly alſo divided, and placed near one another.*

F. *The interiour compounded Tendon entring the middle of the Fleſh.*

THE ANATOMY OF THE BRAIN.

The Authors Epiſtle Dedicatory to his Grace Gilbert *Archbiſhop of* Canterbury, *&c.*

Moſt honourable Prelate,

ONCE more your *Sidley* Profeſſor and your Servant (the more happy Title) flings himſelf at Your feet, with this only Ambition, that he might render ſomething of Thanks for Your Kindneſs and benefits, and that our Labours might chuſe ſuch a Patron, that might give Credit to the Author. But I fear, leſt by my repeated Duty I may ſeem troubleſom, and no leſs in acknowledging Your Benefits, than others in ſuing for them: But ſo great is my Gratitude, and ſo exceeding is your good Nature, that they cannot be crowded into a little compaſs, much leſs wearied out or drawn dry.

But there is another reaſon, which if it doth not command what I do, may at leaſt excuſe and defend it. For when I had reſolved to unlock the ſecret places of Mans Mind, and to look into the living and breathing Chapel of the Deity (as far as our weakneſs was able) I thought it not lawful to make uſe of the Favours and Patronage of a leſs Perſon, neither perhaps would it have become me. For You indeed are He, who moſt happily preſides (both by Merit and Authority) over all our Temples and Sacred Things. Therefore after I had ſlain ſo many Victims, whole Hecatombs almoſt of all Animals, in the Anatomical Court, I could not have thought them rightly offered, unleſs they had been brought to the moſt holy Altar of Your Grace.

I am not ignorant, how great the labour is that I undertake: For it hath been a long while accounted as a certain Myſtery and School-houſe of Atheiſm to ſearch into Nature, as if whatever Reaſons we grant to Philoſophy, ſhould derogate from Religion, and all that ſhould be attributed to ſecond cauſes, did take away from the firſt.

But truly, he doth too much abuſe the Name of Philoſophy, who conſiders the wheels, curious frame, ſetting together, ſmall pins, and all the make and proviſion of a Clock, by which invented Machine the courſe of the Time, the orders of the Months, the changes of the Planets, the flowing and ebbing of the Sea, and other things of that kind, may be exactly known and meaſured, if that at length, when by this his ſearch and conſideration, he hath profited himſelf ſo much, he ſhould not acknowledge the Artiſt, to whoſe Labour and Wit he owes all thoſe things.

I am ſure I am of another mind and opinion, who look into the Pandects of Nature, as into another Table of the Divine Word, and the greater Bible: For indeed, in either Volume there is no high point, which requires not the care, or refuſes the induſtry of an Interpreter; there is no Page certainly which ſhews not the Author, and his Power, Goodneſs, Truſt, and Wiſdom.

In the mean time, there is no right Weigher of things that can lay to our charge as a fault, that we have ſtudied theſe Rolls of Nature, becauſe ſome Atheiſts may be made thereby; which may be objected to the ſtudies of Divines in Sacred Letters, that from their proviſion Hereticks have taken their Arguments and Opinions, and turned them againſt them and Godlineſs.

That I may deal freely, whoever profeſſes Philoſophy, and doth not think rightly of God, I do judge him not only to have ſhaken hands with Religion, but alſo with Reaſon, and that he hath at once put off Philoſophy as well as Chriſtianity. Therefore I deſire, that all mine may be tryed and approved, no leſs by the demonſtration of Piety and Canons of the Church, than by the Rule of Experience and Knowledge, to which I keep: Neither do I intreat and reſpect only the *Mecænas* of humane Arts, but alſo the Primate and chief of Divine, whilſt I openly profeſs my ſelf, with all due obſervance,

YOUR GRACES

Moſt humble and obliged Servant,

THO. WILLIS.

THE

THE PREFACE TO THE READER.

THE Romans ſometimes promiſed to themſelves an Empire, an Eternity by the happy Augury of an humane Head being turned out of the Glebe; neither could they perſwade themſelves, that the Capitol ſhould be the Head of the World, unleſs it had been built upon the Skull of a Man. I do not think of Empires in Arts, nor do I promiſe to my ſelf Trinmphs by overcoming the World of Letters: But in the mean time, I had wholly fruſtrated thoſe Illuſtrious Documents I had long ſince learned, unleſs with thoſe Auſpices I had laboured in Philoſophy, eſpecially the Natural.

For the Province, which I hold in this Academy, requiring that I ſhould Comment on the Offices of the Senſes, both external and alſo internal, and of the Faculties and Affections of the Soul, as alſo of the Organs and various proviſions of all theſe; I had thought of ſome rational Arguments for that purpoſe, and from the appearances raiſed ſome not unlikely Hypotheſes, which (as uſes to be in theſe kind of buſineſſes) at length accrued into a certain Syſtem of Art and frame of Doctrine. But when at laſt the force of Invention being ſpent, I had handled each again, and brought them to a ſeverer teſt, I ſeemed to my ſelf, like a Painter, that had delineated the Head of a Man, not after the form a Maſter, but at the will of a bold Fancy and Pencil, and had followed not that which was moſt true, but what was moſt convenient, and what was rather deſired than what was known. Thinking on theſe things ſeriouſly with my ſelf, I awaked at length ſad, as one out of a pleaſant dream; to wit, I was aſhamed that I had been ſo eaſie hitherto, and that I had drawn out for my ſelf and Auditors a certain Poetical Philoſophy and Phyſick neatly wrought with Novity and Conjectures and had made a Fucus as it were with deceits and incantations for either of us.

Wherefore all delay being laid aſide, I determined with my ſelf ſeriouſly to enter preſently upon a new courſe, and to rely on this one thing, not to pin my faith on the received Opinions of others, nor on the ſuſpicions and gueſſes of my own mind, but for the future to believe Nature and ocular demonſtrations: Therefore thenceforward I betook my ſelf wholly to the ſtudy of Anatomy: and as I did chiefly inquire into the offices and uſes of the Brain and its nervous Appendix, I addicted my ſelf to the opening of Heads eſpecially, and of every kind, and to inſpect as much as I was able frequently and ſeriouſly the Contents; that after the figures, ſites, proceſſes of the whole and ſingular parts ſhould be conſidered with their other bodies, reſpects, and habits, ſome truth might at length be drawn forth concerning the exerciſe, defects, and irregularities of the Animal Government; and ſo a firm and ſtable Baſis might be laid, on which not only a more certain Phyſiologie than I had gained in the Schools, but what I had long thought upon, the Pathologie of the Brain and nervous ſtock, might be built.

But for the more accurate performing this work, as I had not leiſure, and perhaps not wit enough of my ſelf, I was not aſhamed to require the help of others. And here I made uſe of the Labours of the moſt Learned Phyſician and highly skilful Anatomiſt, Doctor Richard Lower, for my help and Companion; the edge of whoſe Knife and Wit I willingly acknowledge to have been an help to me for the better ſearching out both the frame and Offices of before hidden Bodies. Wherefore having got this help and Companion, no day almoſt paſt over without ſome Anatomical adminiſtration; ſo that in a ſhort ſpace there was nothing of the Brain, and its Appendix within the Skull, that ſeemed not plainly detected, and intimately beheld by us. After this, when we entred upon a far more difficult task, viz. the

Anatomy

Anatomy of the Nerves, then very much appeared the plainly to be admired skill of this Man, as alſo his indefatigable Induſtry, and unwearied Labour: For having proſecuted, with a moſt exact ſearch, all the divarications, wandring on every ſide of the Nerve, how minute or ſmall ſoever, and immerſed, and variouſly infolded within other Bodies, and ſo turning over the Labyrinths of the Branches, and ſhoots of every pair, far and near diffuſed, he drew out with his own hand the Schemes, Images, or Draughts of them, and alſo of many paſſages of the Blood, as they appear in this Tract; which indeed, that they might be faithfully and moſt exactly ſhewn, without any falſity or errour, he cauſed, that no Table might contain ſcarce any line or the moſt light paſſage, whoſe conformation and exact habitude he had not found proved by the marks or inſpection of many Animals for that purpoſe killed.

Beſides the helps brought me by his moſt skilful diſſecting hand, it becomes me not to hide, how much beſides I did receive from theſe moſt famous Men, Dr. Thomas Millington *Doctor in Phyſick, and Dr.* Ch. Wren *Doctor of Laws, and* Savill *Profeſſor of Aſtronomy; both which were wont frequently to be preſent at our Diſſections, and to confer and reaſon about the uſes of the Parts. Beſides, the former moſt Learned Man, to whom I from day to day propoſed privately my Conjectures and Obſervations, often confirmed me by his Suffrage, being uncertain in my mind, and not truſting to my own opinion. But the other moſt renowned Man, Dr.* Wren, *was pleaſed out of his ſingular humanity, wherewith he abounds, to delineate with his own moſt skilful hands many Figures of the Brain and Skull, whereby the work might be more exact.*

But although inſtructed by theſe helps, and as it were hem'd in by the plentiful aſſiſtances of theſe Illuſtrious Men, I come forth on the Stage, I preſume I ſhall not be however ſafe from calumny, and free from blame and moſt juſt reprehenſion: becauſe here is inquired into the receſſes and moſt inward dens of the Brain, and its depending parts as it were ſhut and ſealed up; concerning the certain uſes of which, ſcarce any thing may be brought forth, but that, as it may be publiſhed and ſhewn, for the Judgments of the more Learned, ſo it may be carpt at and torn by the opprobries of detractors. In other parts, where matters appear to the Senſes, we do not ſo eaſily run upon errours. For in moſt of the Viſcera and Veſſels, the Contents and contained humors, as alſo their paſſages within the larger Cavities of the containing parts, are diſcerned by the ſight: But in the Brain and Nerves, neither the ruſhings on or impreſſions, viz. *the Animal Spirits themſelves, nor their tracts or footſteps, can any ways be ſeen. Wherefore to explicate the uſes of the Brain, ſeems as difficult a task as to paint the Soul, of which it is commonly ſaid, That it underſtands all things but it ſelf: for in truth, the unwearied labour of the Brain beholds or ſearches the hidden places of other Bodies, in the mean time the œconomy or regiment of its own Family and Kingdom being wholly hid and unknown.*

But what we profeſs to be performed by us in the following Tract, and hope for the future from the help or labour of others, is chiefly this; to wit, that we have not raſhly deſcribed the parts themſelves, of which the Anatomy is inſtituted, but that we have with diligent care and great truſt collected the various appearances and Arguments of Obſervations by a manifold Diſſection. Which things, if you ſhall delineate out of thoſe Sentences and granted Decrees, as it were to a Mathematical Rule, and from thence would collect a Theory as yet lame, and that may not appear abſolute in all its numbers, no doubt but that a longer time, and the getting of more Obſervations may give it a more perfect form, that Antiquity may not have ſaid altogether in vain, That Minerva *was born from the Brain,* Vulcan *with his Inſtruments playing the Midwife: For either by this way,* viz. *by Wounds and Death, by Anatomy, and a Cæſarean Birth, Truth will be brought to Light, or for ever lye hid.*

THE

THE ANATOMY OF THE BRAIN.

CHAP. I.

The Method or Anatomical Adminiſtration of Diſſecting the Brain is propoſed.

AMong the various parts of an animated Body, which are ſubject to Anatomical diſquiſition, none is preſumed to be eaſier or better known than the Brain: yet in the mean time, there is none leſs or more imperfectly underſtood. All of it that appears, and is commonly deſcribed in the forepart or forehead, is beheld almoſt at a ſight or two after ſome rude cutting up; but if you ſeek what lyes hid in the receſſes for that end, new boſoms and productions of Bodies, before hid, are every where laid open: yea the parts of the Brain it ſelf are ſo complicated and involved, and their reſpects and habitudes to one another ſo hard to be extricated, that it may ſeem a more hard task to inſtitute its perfect Anatomy, than to delineate on a plain, the flexions and Meanders of ſome Labyrinth: Becauſe, as we are not able to eſtimate the meaſure or to paint forth the pattern or draught of the frame of this, ſo neither of that, unleſs the bulk or ſubſtance of the ſubject be firſt ſearched to the bottom, and its frame broken into pieces. Hence it came to paſs, that the old Anatomiſts in diſſecting the Brain, not ſufficiently attending what was placed firſt, what ſecond, and what after that in the order of Nature, cut its Glebe as it were into ſlices or parts, and the Phænomena ariſing by chance from ſuch a diſſection, they eaſily eſteemed for true parts of the Brain; when yet in the mean time, by others from a diſſection otherwiſe made, the parts and proceſſes of it appear far different from the former. The reaſon of which is, becauſe the ſubſtance or frame of the Brain and its Appendix lyes ſo within the Skull, that there are many ſwellings or tuberous riſings, with ſeveral tails or little feet compacted together: all which, although diſtinct one from another, and are endued with figures diverſly expanded; yet they, that they may be contained in a leſſer room, are thruſt as it were into the ſame Globe, and ſo complicated among themſelves, that it is a hard thing to find out where the beginning and end of the Brain, as alſo where the limits and partitions of the near adjoyning parts do remain; further, that the ſeveral parts of the Encephalon ſo complicated, may retain their ſite, nor preſently being looſned one from another, may ſpring forth, they are knit together into due foldings, with Fibres and Membranes ſtretched out from part to part. And as often as the ſubſtance or bulk of the Brain ſo conglobated or rolled together is cut, there is as often a neceſſity that the ſlips being cut, the portions of divers parts cleaving together, are carried away with them. Wherefore that a true and genuine deſcription of the Brain might be ſhewed before its ſubſtance and continuity is diſſolved, before all things its whole frame or ſubſtance ought to be explicated, and the knitting of the Membranes being wholly looſned, the ſeveral parts ought to be turned over and ſtretched forth into their proper dimenſions. By what means theſe things may be done, and by what Method the diſſection or Anatomical adminiſtration of the Brain may be beſt performed, ought here in the firſt place to be ſhewn; then theſe things being firſt done, we will more largely deliver the Deſcription of the Brain, together with the uſe and action of its ſeveral parts.

That

That the perfect knowledge of the Brain and its parts may be gained, it is neceſſary not only to diſſect and look into mens Heads, but all other kind of living Creatures heads; for beſides, that the humane Heads or Bodies are not ſo readily to be had, that one may from day to day behold the Brain and its frame, and carefully conſider the ſituation of the parts, and ſearch one after another their reſpects, habitudes, and dependencies; beſides alſo the immenſe bulk of an humane Head is in it ſelf an hinderance, whereby its moſt intricate frame and various receſſes and Appendices are the leſs accurately diſcerned and inveſtigated: all which being reduced into an Epitomy, are plainly repreſented more commodiouſly in the diſſection of Beaſts. Wherefore when the form and compoſition of the Brain in a Dog, Calf, Sheep, Hog, and many other four-footed beaſts, were little different (the magnitude only excepted) from the figure of the ſame, and the diſpoſition of the parts, in a man, I was the more ſatisfied to compoſe a certain Anatomy of the Brain by the frequent diſſection of all ſorts of living Creatures. And in this imployment, for that I ſhall ſhew the communities and differences which the ſubjected parts obtain in various Animals, compared among themſelves, and with man; certainly from ſuch a compared Anatomy, not only the faculties and uſes of every Organ, but the impreſſions, influences, and ſecret ways of working of the ſenſitive Soul it ſelf will be diſcovered. Concerning the Heads of living Creatures, in the diſſection of which it happened for us chiefly to be exerciſed, it was obſerved, as to the chief parts of the Head, that there was a notable Analogy between Man and four-footed Beaſts, alſo between Birds and Fiſhes: For when the firſt Inhabitants of the new-made World were produced, as one day brought forth Fowl and Fiſhes at once, another in like manner Man and four-footed Beaſts, ſo there is in either twin ſpecies a like form of the Brain; but between that Child of the former, and this of the following day, there is found a great difference as to thoſe parts. For as much therefore as Men and four-footed Beaſts have got more perfect Brains, and more alike among themſelves, we have ordered our Obſervations from their Inſpection: Then afterwards we ſhall deliver the Anatomy of the Brain in Fowl and Fiſhes. And here firſt concerning the Heads of Men and four-footed Beaſts, (as we hinted but now) we will propoſe a Method of Diſſection it ſelf, or of Anatomical Adminiſtration, and will at once recite all the parts one after another, and as it were in a compendious Catalogue; then we will by and by more largely draw out the Particles of the Brain and of its Appendix, ſo ſhadowed, in a ſhort Table, and will deſign their uſes and actions for the exerciſe of every faculty.

When therefore we had in our hands the Head of a Man, or Dog, Calf, or Sheep, its more outward coverings were taken off; concerning which, as they are well enough known, we are not at all ſolicitous; then the covering of the Skull being divided by a Saw or Inſtrument, and taken away, on every ſide the bones are broken off with a pair of Sciſſers or a Penknife to the Baſis of the Skull, that ſo the Contents might, as much as may be, be all made plain or open to the Spectators. What therefore comes firſt in view is the hard Meninx including all the reſt with a common covering. This Membrane outwardly and above is knit to the Skull in divers places, eſpecially about the Sutures; but indeed about the foot or Baſis it moſt ſtrictly cleaves to the bones, ſo that it cannot eaſily be pulled away. Inwardly (or in its hollow ſuperficies) it is lax and looſe enough, unleſs that nigh all its boſoms by the inſertions of the Veins, and in the Baſis of the Skull by the Arteries and the Nerves it is tyed to the *Pia Mater*.

This ſame Membrane between the *Interſtitia* or diviſion of the Brain, and beſides of the Cerebel it ſelf inſinuating it ſelf deeply on one ſide, and riſing up again on the other, leaves ſome duplicatures or infoldings, in which, being ſhut up above by the increaſe of the ſame Membrane, Cavities, which they commonly call Boſoms, are formed: to wit, by this means, almoſt the three firſt boſoms are conſtituted; but the fourth is a ſmooth and longiſh, and alſo hollow proceſs of the ſame Membrane, which is ſent through the *Interſtitia* of the Brain, nigh the end of the callous body, even to the pineal *Glandula*. The Cavities of the greater Boſoms are ſevered in many places, as it were into little Cells; as it ſeems for that end, that the blood paſſing ſo through the various turnings in thoſe ends, may be hindred from a more rapid motion.

Beſides, this Meninx or Film of the Brain admits two Arteries from either ſide, one conjugation of which ariſes not far from the Carotick Arteries through the holes of the Cuniform bone, but the other from the bone of the Forehead: all which indeed being diffuſed through the exteriour ſuperficies of the Membrane, water it; but are terminated, partly in the Skull, eſpecially nigh the Sutures, whither they convey the blood, and partly in the boſoms, where, what is ſuperfluous is laid up. Moreover, theſe Arteries perforate the hard Meninx in ſeveral places on the top of the Brain (as *Webſer* obſerves) and impart ſome ſhoots to the *Pia Mater*. Laſtly, the exteriour ſuperficies of this Meninx is no where planted with ſo many ſhoots of Veins as Arteries; but from its four Boſoms (which are the veinous Receptacles of the blood) many Veins go out through the interiour ſuperficies of this Membrane, which being inſerted in the *Pia Mater*, are preſently diſperſed through its whole compaſs, and the ſame ſliding down on every ſide from the boſoms, meet every where the Arteries aſcending from the Baſis of the Head, and being intermingled with them, conſtitute the manifold infoldings of the Veſſels.

That theſe may be the better beheld, after the Arteries are ſufficiently noted, let the hard Meninx be cut round near the border of the broken Skull; then let whatever of it ſerves for a covering and partition to the Brain and Cerebel, be lifted up, that the goings out of the Veſſels, *viz.* the Veins and their diſtributions into the *Pia Mater* may be conſidered: which being afterwards broken aſunder, let the Membrane with its boſoms be wholly taken away; but the reliques of this Membrane,

which

which ſtick to the bones at the bottom of the Skull, ſhould be ſeparated, ſo that the whole frame or ſubſtance of the Brain and its Appendix may be ſomewhat elevated, and moved here and there, be every where conſpicuous, and at length taken from the Skull. But that theſe things may be performed, you muſt begin from the anterior or fore part, where the bone of the Forehead ſeparates it.

Therefore if the prow of the Brain, hid under this bone, be a little lifted up, the mammillary proceſſes come preſently in ſight, together with the ſmelling Nerves hanging to them: which being diſſected near the Inſertion, there will appear an hollowneſs in either proceſs. Theſe are large and round, alſo full of clear water in Calves: but in either ſmelling Nerve a manifeſt Cavity is found continued on either ſide to the anterior Ventricles of the Brain, to which if a Pipe be put and blown into, preſently the whole ſubſtance of the Brain will ſwell.

Next the ſmelling Nerves about the Cocks comb, two ſmall Arteries are ſeen to ariſe from the Skull, and to be carried towards the *Interſtitium* of the Brain, which in truth are branches of the Carotides, which are knit to the dilated Comb before, and from thence are ſeen to be reflected to the anterior Brain.

Theſe Veſſels being there diſſected, the coming together and going out of the Optick Nerves follow, the trunk of which being cut off a little lower, the Tunnel, and out of both its ſides the Arteries called *Carotides*, ariſing out of the Cuniform-bone, do appear; which are more clearly beheld, if the Brain be lifted up. Theſe alſo being cut off, and the Brain farther bent back, the moving Nerves of the Eyes preſently ſhew themſelves; and ſo from thence the other pairs of Nerves follow in order, that one pair of them being cut off, and the Brain with its Appendix more lifted up, the next is ſtill obvious to thoſe beholding it, till all the Nerves ariſing within the Skull, and alſo the Arteries, both the Carotides, and the Vertebral being at length cut off, the whole frame of the Head may be taken out of the Skull.

But (that theſe Veſſels may be deſcribed in the ſame order as they are met with in the cutting them up) two ſmall Nerves follow after thoſe moving Nerves of the Eyes, which, for a reaſon hereafter rendred, we call Pathetick. Theſe Nerves higher than the reſt, ariſing behind two round Prominences called *Nates* and *Teſtes*, (the Buttocks and Stones of the Brain) and bending down forward, and entring for a little ſpace under the *dura Mater*, then coming out through the ſame hole, together with the former, from the Skull, are propagated into the ſight of the Eye. This pair is called by *Fallopius* the eighth, by us the fourth.

Beneath theſe little Nerves, from both ſides of the annulary protuberance, (which being ſent from the Cerebel compaſſes the oblong Marrow) two Nerves of noted magnitude ariſe, which, after they have paſſed through the *dura Mater*, ſend forth another notable branch on either ſide ſtraight down without the Skull, the other branch, by a longer tract, paſſing through both ſides the Skull near the Turky Chair. Theſe Nerves (as is ſhewn afterwards) having gotten a larger Province, are inlarged in the Palate, the parts of the Mouth and Face, and alſo their branches in the Noſe and Eyes, yea they impart roots to the intercoſtal Nerve. We call this pair the fifth, commonly eſteemed the third.

Nigh to the beginning of theſe, out of the loweſt foot of the oblong Marrow or Pith, two leſſer Nerves, endued with a ſingle trunk, ariſe, which being dilated forward, and preſently entring under the *dura Mater*, come out of the ſame hole with the moving Nerves of the Eyes, and are all carried into the balls of the Eyes. This pair is called by us the ſixth.

Next to theſe Nerves follow the auditory or hearing pair, which indeed ariſes higher from the ſides of the oblong Marrow, in what part the Cerebel is hanged to it; *viz.* nigh the leſſer annulary proceſs; from whence it is immediately carried with a double proceſs into the hole of the ſtony Bone: one of its branches is harder, ſerving chiefly for motion; the other altogether medullary and ſofter, as it were only deſtinated to ſenſe.

A little lower ariſes the wandring pair, which is commonly called the ſixth. This ſeems to be made of many Nerves, many of which ariſe together; and to them comes another, endued with a greater trunk, which being brought from the end of the oblong Marrow, yea beyond this, out of the ſpinal Marrow, is united with the former. And ſo all being made like a bundle of Nerves, go out through the hole of the hinder part of the Head; through which alſo goes out the greater branch of the internal jugular Vein. This is by us called the eighth pair.

Under the wandring pair, almoſt out of the Baſis of the oblong Marrow, another pair ariſes, conſiſting alſo of many Fibres, which going ſtraight down, and being preſently immerſed in the *dura Mater*, comes forth again through a peculiar hole out of the Skull; then either Nerve being inoculated into the trunk of the wandring pair, is preſently bended back towards the Tongue. In a man a peculiar protuberance grows above the oblong Marrow, out of which the beginning of this Nerve proceeds. This we call the ninth pair.

Below this, in the loweſt part of the hinder part of the Head, out of the ſides of the oblong Marrow, where it is about to go into the ſpinal, another pair, conſiſting alſo of many Fibres, ariſes; which tending towards the ſpinal Marrow, enters the *dura Mater* at the ſame place where the Vertebral Artery aſcends into the Brain; yet it ariſes out of the boſoms of the bones, but below the firſt Vertebra or Joynt, from whence it is carried into the Muſcles of the hinder part of the Neck, ſo that it is doubtful, whether this pair ought to be called the laſt of the Skull, or the firſt of the *Vertebrals*.

When theſe parts, *viz.* the aforeſaid Nerves and Arteries, both the *Carotides* and the *Vertebrals*, with the jugular Veins (by which the *Encephalon* is faſtned to the foot or baſis of the Skull) are cut off, and their ends ſtretched out as much as may be; either let them remain in the taken out ſubſtance or frame, whereby the beginnings of all the Nerves may be plainly noted; or the trunks of them being cut off near the roots, may be left in the holes of the Skull, whereby their goings out and diſtributions may be obſerved. The images of either Example are delineated in the firſt and ſecond Table.

The buſineſs of Diſſection being thus far brought, the reſidue of the Skull ſhews many things worthy conſideration, of which we ſhall ſpeak particularly afterwards. But firſt we ought to view throughly the taken out frame or ſubſtance of the Brain, together with its Appendix, and to examine all its appearances as they follow in the order of Diſſection.

The ſubſtance or Bulk being taken out, which is of a ſomewhat round figure or ſpherical, it exhibits to the ſight in its ſuperiour and convex part the Brain and Cerebel; but the oblong Marrow, with the utmoſt borders or edges of the ſuperiour bodies, poſſeſſes almoſt all the baſis or its loweſt part. The thinner *Meninx* covers theſe three placed near, and the outward ſuperficies of them all: nor doth it clothe the ſame looſly, but deeply inſinuating it ſelf into all their cavities and receſſes, covers and binds them ſtrictly. And as this Membrane is every where interwoven, with the folds of the Veſſels, by its ſtretching out, it reaches the ſame to every part and portion, and ſo waters the whole with a ſufficient afflux of blood. Here we muſt conſider the Veſſels of this Membrane and its protenſion.

As to the former, the whole ſuperficies of the frame of the ſubject may be ſeen, covered with the infoldings of Veſſels, as it were with a net admirably variegated or flouriſhed, and its ſight or aſpect ſhews like the picture of a fruit-bearing wood; the *Idea* of which, the Veſſels of the Brain more aptly repreſent, and are themſelves ſeen better and more diſtinctly, if you firſt ſquirt into the Carotidick Artery ſome black liquor. The Veſſels interwoven within the thin *Meninx* or *Pia Mater* are Arteries and Veins. The Arteries are four, *viz.* two *Carotides* and two *Vertebrals*. Out of either ſide of the Tunnel the ends of the cut off *Carotidick Arteries* ſhew themſelves, the trunks of which aſcending upwards, are preſently diffuſed from either ſide into the anterior and poſterior, or fore and hinder branch. Either pair of theſe inclining one towards the other, are mutually conjoyned: moreover, the poſterior branches ſo joyned, are united with the Vertebral branches (growing together firſt into one trunk.) For the Vertebral Arteries, ariſing from the laſt hole but one of the Skull, fall at firſt divided through the ſides of the oblong Marrow; then united in its baſis, they go into a ſingle chanel, which meeting with the hinder branches of the *Carotides* (as it is ſaid) it is joyned with them; and from that place of the joyning of them togethr, a noted branch aſcends on either ſide under the edge or rim of the Brain, which being dilated upon the ſhanks or ſtocks of the oblong Marrow, is cleft or divided into very many ſmall ſhoots like hairs, ſome of which aſcend to the Glandula's placed behind the Cerebel, but the reſt make the arterious part of the *Choroidal* infoldings. The anterior branches of the *Carotides*, before they are united, ſend from themſelves on either ſide a noted branch, which creeping upwards like a bounding River, diſtinguiſhes either Hemiſphere of the Brain as it were into two Provinces; but after the aforeſaid branches are united, preſently departing again from one another, they are carried to the Prow of the Brain, and from thence bending back between its *Hemiſpheres*, they fall upon the callous body. All theſe Arteries, before and after their mutual joyning together, ſend forth ſhoots and little branches on every ſide, which do not only creep through and intimately bind about the utmoſt compaſs of its Sphere, but its *Penetralia*, and more inward receſſes, like the young branches of Vines. The ramifications or theſe ſorts of branchings, both of the *Carotides* and of the *Vertebrals*, are ſhewn in the firſt Table, as they are found in a Man, and as a Sheep in the ſecond Table.

Moreover, this thinner *Meninx* or *Pia Mater*, cloathing the whole Brain, and its parts, as it receives the *Arteries* aſcending (as hath been ſaid) from a four-fold Fountain, ſo it is ſtuffed throughout with Veins, ſent from four boſoms. Theſe Veſſels mutually meeting, are complicated together, and almoſt every where conſtitute by their branches derived from both, and meeting one the other, and variouſly contorted among themſelves, the net-like or retiform infoldings; which indeed are not only outwardly in the ſuperficies, but in the diſſection, where-ever you may ſeparate one part from another, without breaking it, theſe kind of infoldings of the Veſſels are to be found. Becauſe, if you behold this frame, taken out of the Skull, collecting together the tops of all the turnings and the *Interſtitia* in this Membrane, and covering them with the joynings of the Veſſels, it will make the whole compaſs or frame of the *Encephalon* appear like a curious quilted ball. But if you go on to caſt abroad this Sphere, and to ſeparate the cleaving parts, knit together, of this Membrane, one from another, you will ſoon find, that this *Meninx* covers the gapings of the crevices or turning chaps of the Brain, binds the *Interſtitia* of either moiety or Hemiſphere, draws together the hinder part of the Brain, otherwiſe being lax and hanging looſe, and compaſſing about every border of it, as it were with a Welt, knits it to the oblong Marrow: and what is the chief of all, the univerſal Cortical or ſhelly ſubſtance of the Brain (to wit, in which the animal Spirits are procreated) is covered over with this Membrane planted with moſt frequent infoldings of the Veſſels; notwithſtanding the interior ſuperficies of the Brain being ſtretched out, (which being called the Callous body, is altogether medullary and white) is not cloathed with this *Membrane*: but inſtead of it many foldings of veſſels, commonly called *Choroides*, are hung and as it were freely flow within its complicature. The reaſon of which is, becauſe as this part, to wit, the callous body, is rather deſigned for the Circulation than for the generation of Spirits, therefore it admits not a more plentiful influx of blood: nevertheleſs, for as much as there

is

is need of heat, whereby the Spirits may be there more eaſily circulated, the blood being moved, within the Veſſels hanging there through the empty ſpace, might afford heat as it were from a fire kindled within a Stove. But within all the other receſſes of the Brain, and beſides, within the folds or lappets of the Cerebel, yea, and the *Interſtitia* or gaps of both theſe, and of the oblong Marrow, this Meninx inſinuates it ſelf, and inſerts the diſtributions of the Veſſels. In truth, the protenſion or out-ſtretching of this Membrane ſeems therefore the more admirable, becauſe having no where a peculiar place of its origine, it not only binds about the Head or *Encephalon* with a common covering, but alſo cloaths all its parts with proper coverings, and knits together their tops and proceſſes. Yea, this *Meninx* ſeems to enjoy a manifold and divers original: for where-ever the gapings or *Interſtitia* of any parts or proceſſes happen, portions of this Membrane there ſpringing forth, cover them all, and gather them together, and reach to them the ramifications or branchings of the Veſſels. In a moiſter Brain this Meninx may be eaſily ſeparated, and ample and large portions of it pulled away with the fingers; which being drawn away, the inſertions of the Veſſels, into the ſubſtance of the Brain and its Appendix, every where clearly appear. Laſtly, by this means the brain being thus left naked, unclothed of its Membranes and Coverings, its make or fabrick, and the diſpoſition or order of all its parts are next ſubjected to Anatomical Inſpection.

That the Anatomy of the Brain, properly ſo called, might be rightly celebrated, I judge we ought not to proceed after the common way of Diſſection. But when as the ſubſtance of the whole Head, taken out of the Skull, ſtands in view, firſt let the hinder partition of the Brain, where it is knit to the Cerebel and oblong Marrow or Pith, the Membranes being every where cut or pulled off, be freed (as much as it may be) from its cleaving to the ſubjected parts; then it will eaſily appear, that the ſubſtance of the Brain is not united to thoſe bodies, but of it ſelf is altogether free and independent of them, unleſs where it is joyned towards the ſuperficies by the knitting of the Membranes. Alſo this keel or hinder part of the Brain being divided by this means from the neighbouring parts, if the fore-part be bent back, the ſhanks of the oblong Marrow will appear wholly naked, and diſtinct from the Brain and Cerebel (unleſs where they are in ſome places hung to it.) Moreover, when the partition of the Brain, being looſned from its coheſion, is lifted up, the three Ventricles, commonly ſo called, go into one empty ſpace or mere vacuity, reſulting from the complication of the Brain. Beſides, it may be obſerved, how the Brain before is only united to the oblong Marrow; and that in two places of its ſhanks, as it were the tops, it is fixed; which *Fornix* ſo called, or arched Vault, is as it were a ſtring or ligament, which ariſing before, where the Brain is hanging to it, is carried to its hinder border, to which it is united as it were with two ſtretched out arms, and ſo it holds together the whole frame of the brain, leſt it be rolled out into a plain, ſtill in a ſpherical figure, and firmly binds the ſame to the ſhanks of the oblong Marrow. From the knitting of the other parts of the humane brain divided and lifted upwards, whereby the vacuity reſulting from its unfolding, and eſteemed for Ventricles, alſo whereby the *Fornix* or arched Vault and Shanks of the oblong Marrow, naked and diſtinct, may be beheld, is repreſented by figure in the fourth Table.

And truly, this Poſition or Aſpect of the Brain, to wit, when its hinder border or partition, being freed from its coheſion by the Membranes to the oblong Marrow, and elevated, is bent forward, expoſes to be ſeen by the eyes themſelves, its whole frame or ſubſtance, to wit, whatever it hath without or within, or before and behind, and alſo plainly detects what its habitude and reſpect is to the other parts. The chief things of theſe I ſhall add, and in the ſame order wherein they occurred to Inſpection.

The figure of the Brain, eſpecially in a man, ſhews ſomewhat globous or ſpherical: the outward ſuperficies is on all ſides noted with chinks turning and winding like to the rollings about of the Inteſtines: each breach or Involution, yea the whole circuit of it contains a twofold ſubſtance, *viz.* the Cortical or rindy, which is the outmoſt and of an Aſh-colour; and the medullary or marrowy, which lyes under it, and appears white. The Brain being as it were plowed with theſe kind of rollings about, like ſo many ridges and furrows, is cleft in the middle, and parted as it were into two Hemiſpheres; yet both the moities come together, and are as it were founded in one like white ſubſtance, which covers inwardly, and as it were in Chambers or Vaults, the whole bulk of the Brain. This is harder than any other portion of the brain, and as it is altogether medullary; it receives all the marrows of the circumvolutions within it ſelf, and is to them inſtead of a common baſis. In either Hemiſphere of the Brain, about the fore parts, this callous body or marrowy ſubſtance, becomes more firm and thick by far than in any other place; and there it is on both ſides faſtned to the tops of the oblong Marrow. From thoſe tops, as it were its beginning, this medullary ſubſtance, covering over or chambering or arching the Brain, is ſtretched out towards the hinder parts, and by degrees leſſens in its thickneſs: at length the outward border of this ſtretched out, is drawn together more narrowly, and more below, it is conjoyned by the knitting of the Membranes and Veſſels (as we but now mentioned) to the tail of the oblong Marrow. Beſides, for its more firm connexion, a medullary proceſs ariſes from the fore part of the callous body towards the tops of it, which ſtretching under the fiſſure or cleft of the brain, reaches to its border; to which it is united, as it were with arms bending on either ſide: which arms indeed embrace the tail of the oblong Marrow, and ſo more firmly knit to it that border of the Brain.

This medullary proceſs, commonly called the *Fornix*, under its riſe or beginning, hath two white and medullary roots, either of them alike going out from the callous body, which roots nigh the tops, where the brain is hung to them, meeting together, paſs into the *Fornix* or Vault it ſelf, as if it were a broad proceſs, which ſtretches under the chamber of the brain, like a beam. Under this twofold root of the *Fornix* is laid croſs-wiſe, of the ſame magnitude, a medullary trunk, by which, like a bridge, there is a certain paſſage and communication between two proceſſes of the form of a Lentil, and chamfer'd or furrowed bodies beaming or ſhining in them. Further, from the midſt of the ſuperficies of this *Fornix*, a thin and pellucid hedge or pale is erected, which is affixed to the chanel or furrow of the callous body, almoſt along its whole paſſage. And for this reaſon, whilſt the three-ſided *Fornix* ſtretched underneath a chamber, ariſing from the complication of the brain, it diſtinguiſhed its appearing cavity as it were into three partitions, and ſo cauſed, that in it three Ventricles were repreſented.

The interior receſſes of the Brain will lye yet more clearly open, if the border, being on every ſide ſeparated and lifted up, as much as may be, from its cohering with the oblong Marrow, be cut a little further through the ſubſtance at the ſides of the ſame Marrow, to which it is united, nigh the chamfer'd bodies, and alſo the *Fornix*, being cut nigh the roots, be bent back, together with the brain; for then the frame of the brain may be wholly lifted up, turned forward, and unfolded into a plain, ſo that the whole interior ſuperficies of the callous body being ſtretched out into a broad floor, may be ſeen and handled. Where, beſides the medullary, and its moſt white ſubſtance, may be obſerved many white parallel lines, which cut the partition of the Brain in right angles, as if they were certain tracts or footſteps, in which the animal Spirits travel from one Hemiſphere of the Brain to the other, and return back again.

After this manner, in very many perfect four-footed Beaſts, the frame or ſubſtance of the Brain was wont to be turned over, the Sphere being projected into a plain, and its interiour ſuperficies to be unfolded into breadth. Alſo this kind of Method of Diſſection may be uſed in a mans brain, where the ſame *Phænomena* wholly occur to Anatomical obſervation. The chief difference is, that the bulk of the brain of a man, for that it is very large, and alſo far thicker, and endued with more turnings and windings; therefore it cannot be ſo eaſily and throughly inverted, as that of a Calf or Sheep, and reduced into a broad plain: yet it may be ſo far expanded and lifted up near its border or partition, that all the interiour receſſes may appear in view. The third and Fourth Figures ſhew the image of an humane brain bent back; but in the ſeventh Table is ſhewn the aſpect or ſight of a Sheeps brain wholly unfolded, and as it were ſpread plain.

In the leſſer four footed Beaſts, as a Mouſe, an Hare, Coney, and ſome others, the ſuperficies of the Brain being wholly plain or even, wants the turnings and windings; however from the complication of the border, and the under-ſtretching of the *Fornix*, there reſults a cavity repreſenting Ventricles.

After that we have throughly viewed all things which belong to the Brain, in the order as we have ſaid, let either Hemiſphere, covered within with the callous body, by which it hangs, be divided and removed from the tops of the oblong Marrow: which indeed may be exactly done, by cutting it near to the ſides of the Lentiform prominencies, which are found in the vulgar diſſection of the Head, within the interior Ventricles: for thoſe prominencies are the tops or heights of the ſhanks of the oblong Marrow, to which the callous body is immediately fixed. When the brain is cut after this manner, that the prominencies, which are the tops of the ſhanks of the oblong Marrow, may be left naked, let them be cut long-ways through the midſt (to wit, in the medullary part, where they are conjoyned to the callous body) and their interior ſubſtance will appear through the whole chamfered or ſtreaked; *viz.* medullary ſtreaks or chamferings are ſeen to aſcend and deſcend forward and backward; that none may doubt, but that theſe chamferings or ſtreaks were made by Nature, as it were paſſages or chanels for the paſſage and return, or going to and fro of the Spirits out of the callous body into the oblong Marrow, and on the contrary. The Figure of the ſhanks of the oblong Marrow, divided from the Brain, with their tops, which are the chamfered bodies, is expreſſed in the eighth Table.

After theſe ſtriated or ſtreaked bodies, the ſhanks of the oblong Marrow being divided for a little ſpace, go forward, then being united, they meet together in the ſame ſtock, made up as it were of two ſtems. But the ſtock or trunk of the oblong Marrow in its whole tract, *viz.* before and after the coalition of its ſhanks, hath many Proceſſes, Appendices, Prominences, and Inſertions of Veſſels, ſome of which ariſe from one ſide, and others from the other ſide, and make it unequal, with various productions and protuberances; of which hereafter.

The

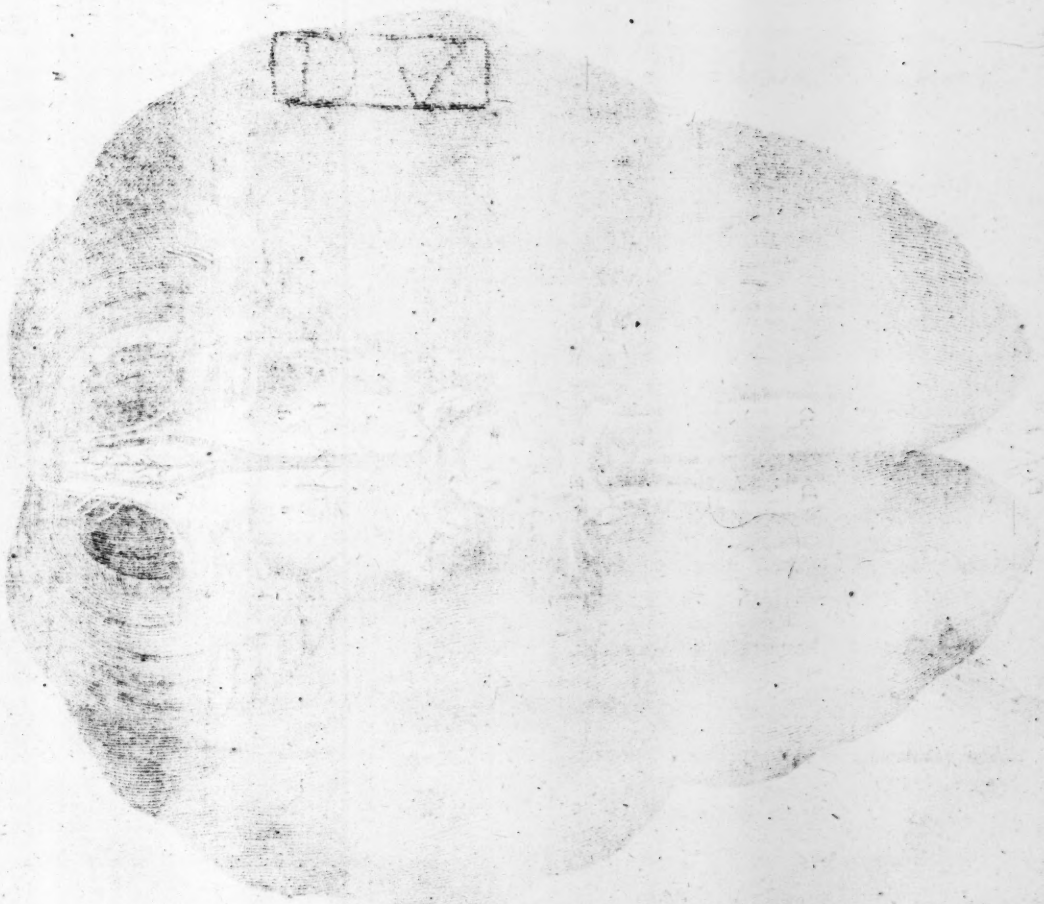

Fig. I.a

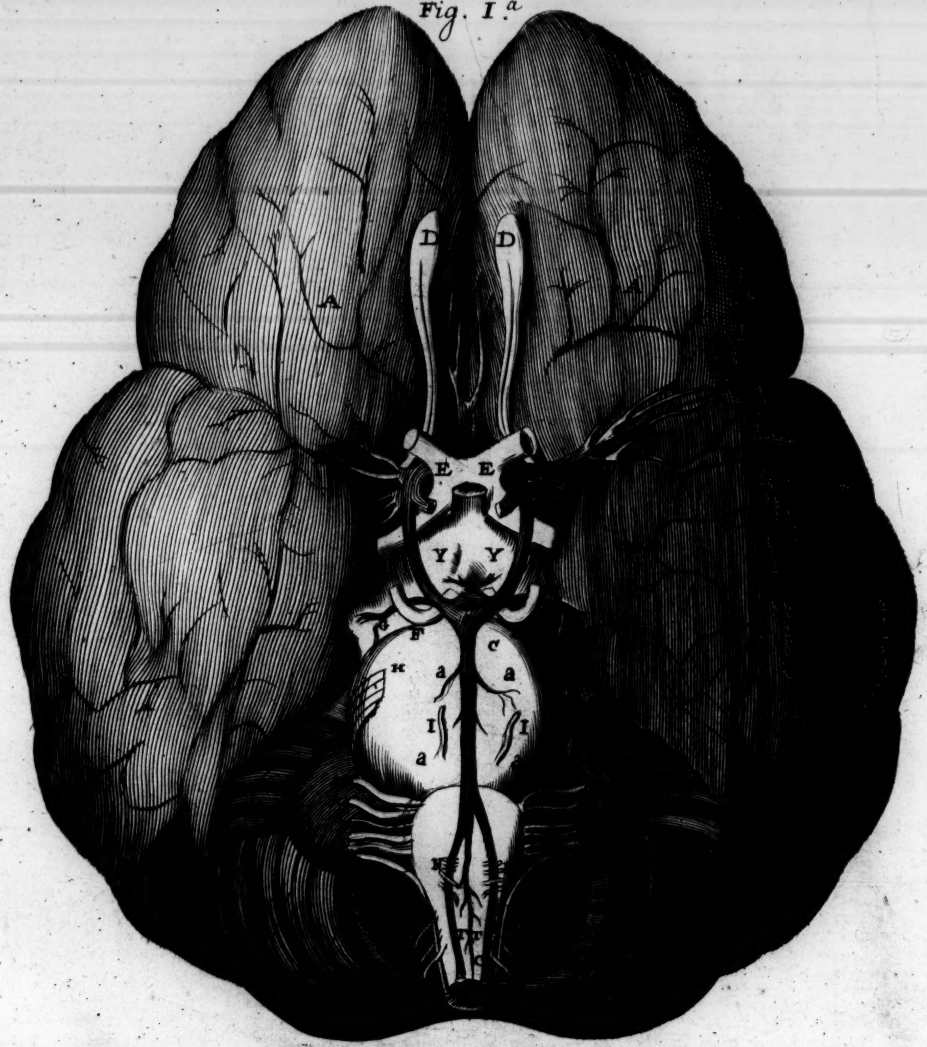

Fig. IId

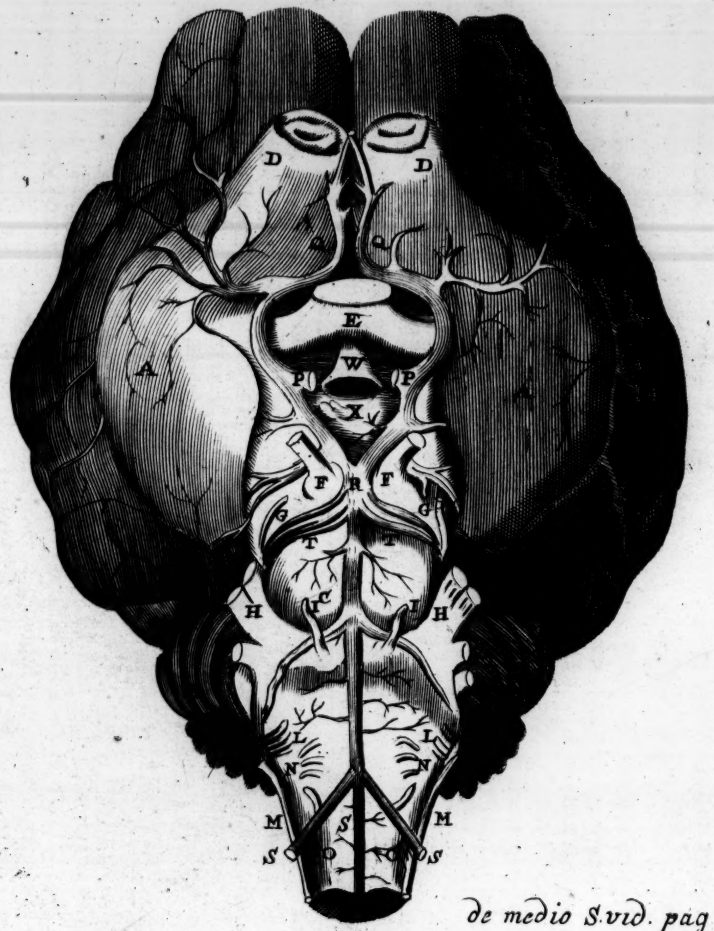

de medio S. vid. pag

The First Figure.

Shews the Basis of an humane Brain taken out of the Skull, with the Roots of the Vessels cut off.

AAAA. *The anterior and posterior Lobes of the Brain quadripartite or divided into four parts.*

BB. *The Cerebel or little Brain in the hinder part of the Head.*

CC. *The long Marrow or Pith.*

DD. *The smelling Nerves or the first pair.*

EE. *The Optick or seeing Nerves the second pair.*

FF. *The moving Nerves of the Eyes the third pair.*

GG. *The pathetick Nerves of the Eyes, or the fourth pair.*

HH. *The fifth pair of Nerves.*

II. *The sixth pair of Nerves.*

KKKK. *The auditory or hearing Nerves, and their two processes on either side of them, the seventh pair.*

LLllll. *The wandring pair, or the eigth pair, consisting of many Fibres.*

MM. *The Spinal Nerves coming from afar to the origine of the wandring pair.*

NN. *The ninth pair consisting also of many Fibres, (which tending downwards, grow together into one Trunk,) which arises a little above the process of the hinder part of the Head.*

OO. *The tenth pair tending downwards.*

PP. *The Trunk of the Carotidick Artery cut off where it is divided into the anterior and posterior Branch.*

QQ. *A Branch of it going in between two Lobes of the Brain.*

R. *The anterior Branches of the Carotides go away united, moving forward into the fissure or cleft of the Brain.*

S. *The posterior Branches of the Carotides united, and meeting with the Vertebral Trunk.*

TTT. *The Vertebral Arteries and their three Branches ascending.*

V. *The Branches of the Vertebrals growing together into one Trunk.*

WW. *The place designed where the Vertebrals and the Carotides are united, and either Branch ascends to the Choroidal infolding.*

X. *The Tunnel.*

YY. *Two Glandula's or Kernels placed behind the Tunnel.*

aaaa. *The annulary Protuberance, which being sent from the Cerebel, embraces the stock of the long Marrow.*

The Second Figure.

Shews the Basis of a Sheeps Brain taken out of the Skull, and the Roots of the Vessels cut off, where all the Arteries, by Ink being injected into one of the Carotides, are made black and more conspicuous.

AA. *Two Hemispheres of the Brain without Lobes, different from that in a Man.*

BB. *The lateral portions of the Cerebel.*

CCC. *The oblong Marrow.*

DD. *The olfactory or smelling Nerves cut off nigh to the mammillary Processes, that their Cavities may appear.*

E. *The Coalition or joyning together of the Optick Nerves.*

FF. *The motory Nerves of the Eyes, or the third pair.*

GG. *The Pathetick Nerves, or fourth pair.*

HH. *The fifth pair: the Trunk of which Nerve is presently divided into two Branches.*

II. *The sixth pair.*

KK. kk. *The seventh pair, or the hearing Nerves, on either side of which are two Processes.*

LL. *The eighth or wandring pair, the origine of which is made up of very many Fibres seeming to grow together.*

MM. *A Nerve coming out of the spinal Marrow to the beginning of the wandring pair.*

NN. *The ninth pair, consisting also of divers Fibres arising distinctly, which afterwards grow together into one Trunk.*

OO. *The tenth pair tending downwards.*

PP. *The Trunk of the Carotidick Artery cut off, where it is divided into the anterior and posterior Branch.*

QQ. *The inosculation of the anterior Branches.*

R. *The posterior Branches of the Carotides united, and meeting with the Vertebral Trunk.*

SSS. *The Vertebral Artery ascending with a triple Branch.*

TT. *Where the Carotides meet the Vertebral, and on either side many Arteries ascend to the Choroidan infolding.*

V. *The coalition or joyning together of the Vertebral Branches into the same Trunk.*

W. *The Tunnel.*

X. *A white Glandula or Kernel placed behind it.*

CHAP.

CHAP. II.

The Parts of the oblong Marrow, and the reſt of the hinder Parts of the Head are recounted, and their Diſſection ſhewn.

HAving deſcribed both the Meninges, and the ramifications of the Veſſels in them, alſo the fabrick of the Brain, properly ſo called; and next ſhewed its outward partition gathered together into folds about the ſhanks of the oblong Marrow, and either middle or marrowy part of it hung to the chamfered bodies; we will now follow the remaining parts of the Head in order.

The chamfered or ſtreaked bodies, or the tops of the oblong Marrow, are two lentiform Prominences, which are beheld within the former Ventricles of the Brain, as they are commonly termed; the heads of theſe, which are more large and blunt, incline mutually one to another, and are almoſt contiguous. Out of the angle of this inclination the *Fornix* ariſes with a double root; to which is ſubjected or underlaid a certain tranſverſe medullary proceſs, and ſeems to knit together theſe ſtreaked bodies, as may be ſeen in the ſeventh Table *GG.* but the ends of thoſe bodies, being made ſharper, are reflected outward, and make as it were two ſides, with a ſharp triangle, to whoſe anterior ſuperficies the marrow of the callous body ſticks for a long tract; where, if theſe bodies be cut long-ways through the midſt, the medullary ſtreaks (as was already ſaid) will preſently appear. The figure and place of theſe, as alſo the medullary chamferings, are truly repreſented in the eighth Table.

Where the ſtreaked bodies end, the chambers or *Thalami*, as they are termed, of the Optick Nerves, poſſeſs the next part to the oblong marrow; to wit, in this place, its ſhanks riſe into unequal protuberances, out of the ridges of which the Optick Nerves ariſe, and from thence, being bent down in the fore-part with a certain compaſs, they joyn together about the baſe of the ſame marrow, and ſeem to be united; by and by being again parted, and going forward towards the ball of the Eye, they go out of the Skull. In this place the ſhanks of the oblong marrow in a Man are for the moſt part diſtinct, and gaping one from another, leave a deſcending opening, which is in the paſſage to the Tunnel; but in moſt four-footed Beaſts the ſhanks of the ſame medullary ſtocks are there diſtinct, only a little lower, and have a chink cut for the Tunnel: but the ridges of them, in which the beginnings of the Optick Nerves lye hid, are ſomewhat conjoyned, and for the ſpace of half an inch do grow together. Wherefore in Brutes there is one hole before this growing together, and another behind it, both which lead towards the Tunnel. The reaſon of this difference is, becauſe in a Man, for that the frame or Subſtance of the brain it ſelf is very large, and that its marrowy parts are remote one from another, it is behoveful for its ſhanks, whereby the tops of the oblong marrow may be the better fitted to the ſame, to be ſeparated, and from their mutual touching to be bent into a greater aperture. Hence it is obſerved, that in a Man the ſhanks of the oblong marrow, from the hanging on of the Brain, go forward with a greater angle of inclination, and with a certain bending compaſs; but in Brutes the ſame lye almoſt parallel. After what manner theſe parts are formed in an humane brain the third and fourth Figure ſhews; after what manner they are in four-footed Beaſts is ſhewn in the ſeventh Figure.

From the ſame ridges of the medullary ſhanks, from whence the Optick Nerves take their origines certain medullary proceſſes ariſing, and being dilated on either ſide above the brim of the ſecond hole, grow together about the root of the pineal *Glandula*. Theſe proceſſes (as it ſeems) are thoſe parts, which the Famous *Cartes* ſuppoſes to be Nerves belonging to the pineal *Glandula*: but I rather ſuſpect them to be productions only, by which the Optick Nerves may alſo communicate near their origines. Their figure is very well deſcribed in the ſeventh Table.

After the *Thalami* or Chambers of the Optick Nerves, other notable protuberances, commonly called *Nates* and *Teſtes*, the Buttocks and Teſticles (of the brain) grow to the ſuperior part of the medullary Trunk or ſtem, and cover its ſuperficies about the ſpace of an inch; and for that they are not contiguous in the midſt, there is under them a certain hollowneſs in their whole tract. Theſe protuberances are leſſer in a Man, alſo in a Dog and Cat; laſtly, if we obſerved rightly, in other living Creatures, which are newly brought forth, that are impotent, and not inſtructed for the finding out of food. In a Calf, Sheep, Hog, and the like, they appear far greater: in Fiſhes and Fowls they are wholly wanting.

In number they are four, *viz.* two grow to either ſide of the oblong marrow. The former called *Nates* or the Buttocks, ſeem the greater and principal; to which the other latter called *Teſtes* or the Teſticles, hang as if growing out of them. As to their figure, they are round, and are commonly taken for two ſhanks on either ſide of the Brain and Cerebel planted near, which being bent inwardly, and turned back one towards the other, are ſaid to grow together, and ſo to conſtitute the oblong marrow. But this opinion, as we ſhall ſhew more largely hereafter, by the diſſection ordered according to our Method,

is

is clearly falſe. For it plainly appears, that the Brain is fixed, long before theſe bodies, to the oblong marrow; nor is there any commerce between theſe and that, unleſs very remote.

But if the ſite of theſe parts, and their reſpects and habitudes to the neighbouring bodies, be well noted, it will appear plainly, that they make as it were a certain peculiar Region wholly diſtinct from the Brain and Cerebel, alſo from the oblong marrow it ſelf. Their ſituation is remote enough from the fore-parts, and ſufficiently ſeparated by the Cavity or Ventricle under-lying from the medullary ſtock or ſtem: yea a proper way, or one proceſs, ſeems to lead from the long marrow into theſe prominences, and another to go from them, and thence to be carried into the Cerebel. From hence we may ſuſpect, that theſe prominences (eſpecially the Native-form, or of the ſhape of a Buttock, which are the chief) are certain places of diverſion, in which the animal Spirits go apart in their paſſage from the oblong marrow into the Cerebel, and from this to that on the other ſide, and there ſtay for ſome animal uſes, of which we ſhall ſpeak hereafter. As to the way, which leads from the oblong marrow into theſe prominences; it is manifeſt, that beneath the origines of the Optick Nerves on either ſide a medullary Proceſs deſcends, with little Villages proper for it ſelf, which terminates in the aforeſaid prominencies. Then, if from theſe, you look for a paſſage out, it is equally clear, that from the hindermoſt prominencies, which are called *Teſtes*, on either ſide, a medullary proceſs doth obliquely aſcend, which being dilated into the Cerebel, is divaricated through its whole frame. But that the Natiform or Buttock-formed Prominences are Principals, and the *Teſtes* their dependences, or the heads of medullary Proceſſes, which are carried from thence into the Cerebel, manifeſtly appears in a Sheep, Calf or Horſe, and in ſome others, where the *Nates* are of a noted magnitude, the *Teſtes* of a very ſmall bulk grow to them, and in the middle between theſe the medullary Proceſſes, the Appendices of the former Prominences, exiſt. The aforeſaid Prominences, as alſo the medullary Proceſſes, which lead forward and backward, to and from them, are aptly repreſented in the fourth Table, but yet more clearly in the eighth Table TT. PP.

Further, becauſe the Animal Spirits reſiding in either Promptuary and Appendix, before they are carried to the Brain, ought to be confounded and mingled together, therefore the two prominences of either ſide do mutually grow together as it were with wings ſtretched out one to another; but for as much as it is behoveful for thoſe growings together to be diſtinguiſhed from the oblong marrow, therfore an hollowneſs comes between, which is by ſome eſteemed the fourth Belly, and by others a paſſage to it. Theſe Prominences in a Man, Dog and Cat, and ſome other Animals (as was above mentioned) are very ſmall, and almoſt even; alſo they appear, as the other portion of the oblong marrow, of a white colour. In a Calf, Sheep, Horſe, and many other four-footed Beaſts, the former protuberances, commonly called *Nates* or Buttocks, are remarkably great, alſo outwardly they appear to be of a fleſh-colour, becauſe they are cloathed with the thin *Meninx* or *Pia Mater*, which contains in it ſelf very many Veins and Arteries; which if ſeparated, the interior ſubſtance of thoſe parts is of a wanniſh colour, and ſuch as is not in all the oblong marrow or pith beſides. But it plainly appears, as in Brutes, ſo in Man, the hinder or poſterior prominences are *Epiphyſes* or additions of the former, and that from theſe additions or dependences the medullary proceſſes aſcend obliquely into the Cerebel; near which, other proceſſes cutting thoſe, deſcend direct from the Cerebel, which ſeem not to be inſerted into the medullary Trunk, but going about it, do conſtitute the annulary or ringy protuberance. This annulary protuberance is greater in a Man than in any other Creature. Beſides, it is obſerved, that where-ever the ſuperior prominence of the Buttock-form is larger, this inferior annulary is very ſmall; and ſo on the contrary. Further, thoſe medullary proceſſes, aſcending towards the Cerebel, communicate mutually among themſelves by the other tranſverſe medullary proceſs; and out of this tranverſe proceſs, two ſmall little Nerves ariſe, the fourth pair of thoſe which we have recounted, and which are called by us Pathetical. Each of theſe, delineated in fit figures, the ſeventh Table ſhews clear enough.

Not far from the aforeſaid Prominences, to wit, between theſe and the Chink, which is called the *Anus* or Arſe-hole, the Pineal Glandula or Kernel is placed. This is put in a Valley, which lyes between the Natiform protuberances, and thoſe which are the Chambers or *Thalami* of the Optick Nerves; in which place that Glandula or Kernel is fixed, ſometimes by very many ſmall Fibres, and ſometimes by two noted medullary roots ſubjected to the part; and beſides it is included in a Membrane, which is a portion of the *Pia Mater*, as in a Cheſt; and as this Membrane is ſtuffed with very many Arteries and Veins, ſome ſmall Veſſels alſo enter into this Glandula.

Under the Prominences but now deſcribed, (as was above hinted) a narrow Cavity or Ventricle is ſtretched out with a long paſſage, which, although it obtains ſome egregious uſes, yet it ſelf ſeems to be only ſecondary, and as it were by chance; for that the proceſſes of either prominence ought to be conjoyned among themſelves, and to be diſtinguiſhed from the under-lying medullary Trunk. Two holes lye open into this Trunk, one of which is placed in the beginning, and the other in the end of it, and through the middle of its paſſage the down-bending aperture tends towards the Tunnel; ſo that the ſerous humor entring at either hole, may preſently ſlide away into the Tunnel. Moreover, into the ſame aperture of the Tunnel there lyes open another paſſage, to wit, through the firſt hole, which is placed near the roots of the *Fornix*; ſo that from every quarter of the Head the ſe-

rosities might be carried into that sink; to wit, that through the first hole, from the infoldings or the anterior Ventricles of the Brain; through the second hole, the humors which are gathered about the orbicular prominences, do come away; and through the third hole, those which are laid up nigh the confines of the Cerebel, do find a passage. These several holes, with the distinct ways to the Tunnel, are plainly delineated in the seventh Table H. M. T.

Above the Pineal Kernel, as it were above the Button, the infolding of the Choroeides seems to be hung; now this infolding is made after this manner: out of either side of the oblong marrow, where the border of the Brain is knit to it, two Arteries arising from the posterior branches of the Carotides, where they are united to the Vertebrals, do directly ascend; which being presently divided, like many Rivers planted near together, are carried towards the pineal Glandula, and there seem to be terminated by a mutual meeting: and in that place, out of the fourth bosom, sent down upon the pineal Glandula, the veinous branches come out on both sides, which in like manner being divided into filaments or small threads, meet with the capillary or hairy Arteries, and are in many places inoculated into them, and variously complicated with them; and so these Vessels, being Net-like, much interwoven among themselves, and interserted with the Glandula's, do constitue the to be admired infoldings. These kind of infoldings of the Vessels, as it were with two out-stretched wings, are thrust out on either side upon the shanks of the oblong marrow, even to the streaked bodies; but yet they only lye upon their superficies, nor are they more firmly affixed either to the oblong marrow, or to the callous body by any insertions of the Vessels; so that the blood seems only to be brought to these places, and carried away without any afflux of it made into the subjected parts; for what uses shall be spoken of hereafter. The Choroidal infoldings, with the pineal Glaudula, are drawn out in the seventh Table. G. F. E.

And thus far concerning the appearances found above the oblong Marrow, between the streaked bodies and the Cerebel; which indeed are almost constantly after a like manner both in Man and four-footed Beasts, unless that they only differ in bigness. Within this space, in the Pedestal or Basis of the same Marrow, many things worth noting occur: For besides the ends of the cut off Vessels, which are above recited, the site and structure of the Infundible or Tunnel deserve consideration. For behind the coalition or joyning together of either Optick Nerve between the shanks of the oblong Marrow there gaping, is sent down a receptacle as it were tubulated or made like a Pipe, covered without with a thin Membrane arising from the *Pia Mater*, and defended within with a medullary substance. The orifice of this is placed higher, between the shanks of the oblong Marrow, and receives their bending aperture; from thence a short Tube or Pipe being sent down, is inserted to the pituitary Glandula or Kernel. We see this Tube in an Horses Brain greater than a Gooses Quill, also shining and full of clear water; that it is not to be doubted, but that by this way the serous humors slide away from the Brein to the pituitary Glandula: but how these humors are carried away from thence, shall be afterwards inquired into, because they are not carried into the Palate or Roof of the Mouth, as is commonly believed.

Nigh the lower border of the Tunnel, in a Man, underneath there are two whitish Glandula's, though in Brutes only one, but greater, is found. What is the proper use of this part shall be told hereafter: in the mean time, whether it be doubled or only one larger, it seems to be as it were instead of a bank to defend or preserve the thin Membrane of the Tunnel, left it should be broken or thrust out of its place: on the other side the growing together of the Optick Nerves serves instead of the same kind of defence.

What besides is contained in this space are only the shanks of the oblong Marrow it self, which proceed directly from the chambers of the Optick Nerves towards the hinder part of the Head in a straight passage; and when both grow together below the Tunnel, they are afterwards distinguished in their whole tract by a line drawn through the midst. These shanks of a mans Brain are far larger than in brute beasts; to wit, in that they seem to be made up of very many medullary cords or strings joyned together in one, as if in this common passage and high-way of the animal Spirits, they were so many distinct paths, which the Spirits enter into respectively, according to the various impulses of sense and local motion. Moreover, this space of the oblong Marrow therefore appears shorter and more broken in a man, because much of it is hid by the annulary protuberance, which is sent from the Cerebel, and is very big. The *Pia Mater*, all about covering the sides of this medullary Trunk, cloaths them with most thick infoldings of the Vessels; by which heat and the nervous juyce are carried, as a continual provision for the Spirits, taking a long journey. Thus much for the first Section, or anterior portion of the oblong Marrow: now our order carries us to the inspection of its hinder Region, to wit, where the Cerebel grows to it; and the Processes sent from this either compass about its Trunk, or are inserted into it; out of which also, the other Nerves produced within the Skull, take their beginnings. Concerning these we will speak in order.

CHAP.

CHAP. III.

A Deſcription of the Cerebel and it Proceſſes, alſo of the hinder Region of the oblong Marrow.

BElow the orbicular Prominences, the Cerebel follows to be inſpected. The figure of this, like the Brain, is ſomewhat globous, alſo it appears unequal, marked with certain turnings and windings about; the ridges and furrows of whoſe turnings about the *Pia Mater* ſtretches over, and reaches out the infoldings of the Veſſels to them all, and deeply inſerts them into all. However the Cerebel is diverſified or variegated with its turnings and rollings about, not as the Brain, after an uncertain manner; but its folds are diſpoſed in a certain orderly ſeries; for the exterior frame of it ſeems to conſiſt of thin lappets, or little rings or circles, being contiguous and infolded, alſo going about through the whole compaſs with a parallel ſite or ſituation.

Either Region of the Cerebel, to wit, the former and the hinder, is terminated in a proceſs in form of a Worm. According to theſe ends, as it were in a double Pole, theſe Circles are very ſhort; thence aſcending towards the top or Equator, they are by degrees enlarged, as it were Parallels in a Sphere or Globe. Theſe Circles are outwardly Cortical or barky, and within medullary, and all their marrowy parts paſs into two ample middles; which indeed ſeem to be the ſame in the Cerebel, as the callous body in the Brain.

The Cerebel in ſome Animals conſiſts of one frame, and all its little circles are placed in the ſame parallel ſite, and keep the ſame proportion among themſelves; but in others there grow to the Cerebel as it were the primary Sphere, and endued with greater circles, ſome other bodies as it were Wens or Extuberances, or additional Spheres marked with leſſer circles. Theſe being eccentrick to the Cerebel it ſelf, have oftentimes labels or folds ordered in a diverſe ſeries from it.

But the Cerebel it ſelf (whether it hath theſe little Excreſcences growing to it or not) is found almoſt in all Animals of the ſame figure and proportion, alſo made up of the ſame kind of labels or lappets. Thoſe which have the Brain diverſly framed from a Mans, as Fowl and Fiſhes, alſo among four-legged Creatures, Conies and Mice, whoſe Brains want turnings about or convolutions, have the like ſpecies and the like diſpoſition of the folds and compoſure of the other parts of the Cerebel. The reaſon of this difference in the brain, and of the conformity in the Cerebel, is rendred hereafter, when we treat of the Uſe of the Parts.

As the Brain, within its Cavity, hath the Choroidal infolding made up of Arteries and Veins variouſly complicated, and of Glandula's thickly interſerted; ſo alſo the Cerebel hath got the like infoldings of Veſſels, and thoſe marked with very many Glandula's, and greater than thoſe in the Choroidal infolding. Theſe infoldings and heap of Kernels, the *Pia Mater* being ſeparated, which clothes the hinder part of the Cerebel, eaſily appear in ſight; for in that place theſe creep upwards on eithe ſide nigh the Worm-ſhaped proceſs, as it were with two branches; and receive the Artery on either ſide, from the Vertebral Artery, lying under the Baſis of the oblong Marrow and the veinous paſſages, ſent from either lateral boſom. We ſhall inquire hereafter into the uſe of this Infolding and of its Glandula's.

In the mean time, that we may deſcribe the ſite and hanging on of the Cerebel; the ſame ſtanding on the oblong Marrow ſeems to be fixed to its ſides, as it were by two little feet; between which, planted on either ſide, and the Cerebel placed above, and the trunk of the long marrow below, (becauſe all theſe ſhould be diſtinct one from the other) there comes a cavity or hollowneſs between, which is commonly called the four Bellies.

In either little foot, ſuſtaining the Brain, are found three diſtinct medullary Proceſſes. The firſt of theſe, ſent from the orbicular Protuberances, aſcends obliquely; the ſecond deſcending ſtraight from the Cerebel, and paſſing through the other acroſs, compaſſes about the oblong Marrow; the third proceſs, deſcending from the hinder Region of the Cerebel, is inſerted into the oblong Marrow, and increaſes its trunk as it were with an additional cord or ſtring. Theſe ſeveral Proceſſes are truly repreſented in the ſeventh Table. Q. P. R.

But as to what belongs to the annular or ringy Protuberance, by which the medullary Trunk, both in Man, and in ſome four-footed Beaſts, is compaſſed about, that is made after this manner. The ſecond or middle proceſs of the Cerebel, deſcending ſtraight to the oblong marrow, ſeems not to be implanted in it, as ſoon as it touches its ſides, but growing into a larger bulk, goes about the ſuperficies of the ſame Marrow with divers circular Fibres. And ſo when in either ſide both thoſe kind of proceſſes of the Cerebel, being dilated or carried from the top of the medullary Trunk towards its Baſis, do mutually meet, they make that circular protuberance. The ſubſtance of this is far larger in a Man than in any other Animal, in an Hare, Rabbet, Mouſe, and the like, it is very ſmall; in Fowl it is either wholly wanting, or for its ſmallneſs ſcarce to be diſcerned by the eyes. Concerning its bulk, this is a conſtant obſervation. They who have the orbicular prominences before the Cerebel ſmall, have this annulary protuberance very big; and on the contrary, they who have thoſe prominences big or very great, have this ring very ſmall: further, they who wholly want the Buttock-form protuberances, as in Fowl, ſeem alſo to want this annulary.

In many brute Animals, but not in Man, nigh to this greater Protuberance, a little lower, another leſſer, in like manner orbicular, ſtands, and compaſſeth about the ſuperficies of the oblong Marrow; the root of which is a white and medullary line, ſtretched out under the Cerebel, above the botom of the fourth Ventricle. From the ſides of this leſſer protuberance the auditory Nerves ariſe: In Man the auditory or hearing Nerves are ſeen to ariſe out of the utmoſt brim of the greater protuberance, in like manner they have for their root a white medullary line covering the fourth Ventricle.

That this line, and the three diſtinct medullary Proceſſes, which conſtitute either little foot of the Cerebel, may be more plainly ſhewn, alſo that the moſt inward frame of the Cerebel may be viewed, its whole Globe ought to be cut through both Poles, *viz.* in the middle through the Vermiform or Worm-ſhaped proceſſes; then it will plainly appear, that in either Hemiſphere there is an ample middle or marrow, wherein the marrowy branches, being ſtretched abroad on every ſide, like thoſe of a tree, ſpread through the Cortical ſubſtance of the Cerebel, every where diffuſed; and that in either middle or marrowy part, the three diſtinct proceſſes, which make either trunk, or little foot of the Cerebel, are inſerted. Each of theſe, are fitly repreſented in the ſeventh Table.

Thus much for the Cerebel, and by what means it is faſtned to the oblong marrow. Beſide theſe it is to be obſerved, that about the bottom of the Baſis of the oblong marrow, out of the greater Ring, come out two medullary ſtrings, which being diſtinct from the reſt of the medullary Trunk, go right forward towards the ſpinal marrow, and in its progreſs, being made ſtraiter by degrees, like Pyramids, after about the ſpace of an inch, end in ſharp points. The extremities of theſe conſiſt on the other ſide, where the wandring pair of Nerves have their original, and make a certain riſing up in the oblong Marrow. Hence it is likely, that theſe ſtrings are paſſages or chanels of the animal Spirits, wherein they are carried from the greater Ring, or what is the ſame thing, from the Cerebel into the wandring pair, and the beginnings of other Nerves implanted near; for what end, ſhall be ſaid hereafter. Theſe pyramidal Bodies do not ſo manifeſtly appear ſo long as the *Pia Mater* clothes them, and hides them with the infoldings of the Veſſels; but this Membrane being pulled away, they are ſo conſpicuous, eſpecially in a Man and a Dog, that they ſeem like greater Nerves. In thoſe Animals, where the annulary Protuberance is greater, theſe proceſſes being brought from the ſame in right angles, are greater and more conſpicuous; and on the contrary, in Fowl they are clearly wanting.

. Concerning this hinder Region of the Head, there is not much beſides worth noting, except the productions of the Veſſels. But there are Veſſels which chiefly belong to theſe parts, the latter ſix pair of Nerves ariſing within the Skull and the Vertebral Arteries. We have already deſcribed in ſome meaſure the beginnings of the former; what belongs to the more full knowledge of them, we ſhall leave to be handled in its proper place. As to the Vertebral Arteries, they reach from about the fartheſt end of the oblong Marrow, now about to end in the ſpinal, to its ſides. Theſe Veſſels, as they are ſmaller, ſo they enter the Skull with leſſer proviſion than the Carotides; for they are neither flouriſhed firſt with Net-like infoldings, nor are carried in a long journey by compaſſing about; but either Artery, paſſing directly through the Cuniform or Wedge-like Bone, embraces the medullary Trunk on either ſide. Although theſe go forward divided for a little ſpace, yet afterwards they are united, and with a ſingle channel or paſſage, they meet with the poſterior Carotides inclining mutually one towards the other; and ſo all the branches, meeting as it were in a threefold way, are inoculated one in another. The Vertebral Arteries, firſt ſhewing themſelves within the Skull, are diſpoſed otherwiſe in Brutes than in men: in the latter they fall through the ſides of the oblong marrow parallel for ſome ſpace, then as it were with a certain ſemicircular compaſs, they mutually incline one towards the other, and preſently meet. The branches which firſt go forwards divided, are ſometimes only two, to wit, one on either ſide, ſometimes three, and then beſides the two former, another is produced in the middle. But in Brutes, either Trunk of the Vertebral Artery, at the firſt coming to the Marrow, inclines preſently to the meeting of the other with an acute angle, and quickly both meet together. The *Vertebrals*, even as the *Carotides*, ſend forth manifold branches in their progreſs with an innumerable ſeries of ſhoots, which cover over the oblong marrow, the Cerebel, and all their cavities and receſſes, and water them all with a plentiful flood of blood.

Theſe are the *Phænomena* or Appearances which the whole frame of the Brain and its Appendix is wont to exhibit to Anatomical Inſpection, and which, as to its fabrick, and all its parts, and proceſſes, are to be found both within and without. As it is a hard and troubleſome buſineſs to inquire into the actions and uſe of each of theſe, ſo it is alſo joyned with ſo much pleaſure and profit, that I dare promiſe to my ſelf and others, that it will be a thing worth our labour and while. Yet before we enter upon this, there remain to be unfolded ſome things hid in ſome of the bones of the Skull, ſuch as are the pituitary Kernels, the admirable Net, and ſome others; alſo we ought to ſhew firſt, briefly at leaſt, a type or figure of the Brains in Fowl and Fiſhes.

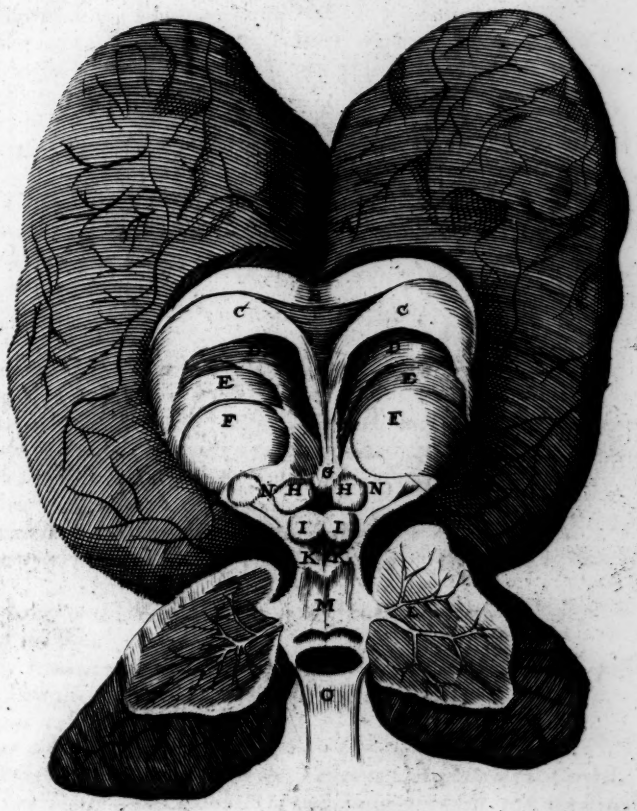
Fig. III.



The Third Figure.

SHews the outmoſt or ſuperiour Superficies of the humane Brain taken out of the Skull; where the border of the Brain being looſned from the knitting of the other Parts, made by the Membranes, is elevated and turned outward, that the ſhanks of the oblong Marrow, the Fornix *or arched Vault, the* Nates *and* Teſtes, *with the pineal Kernel, and other Proceſſes, may be clearly and diſtinctly beheld.*

AA. *The border of the Brain, which in its natural ſituation was contiguous to the Cerebel.*

B. *The brim or margent of the callous Body beſmearing either Hemiſphere of the Brain, which in its natural ſite leans upon the pineal Glandula.*

C. *The* Fornix *or arched Chamber.*

DD. *The Arms of it embracing the ſhanks of the oblong Marrow.*

EE. *The ſhanks of the oblong Marrow, out of which the Optick Nerves proceed, and the tops of which (ſituated further out of ſight) are the ſtreaked Bodies.*

F. *The pineal Glandula, between which and the root of the* Fornix, *ſtands the chink leading to the Tunnel.*

GG. *The orbicular Protuberances which are called* Nates *or the Buttocks.*

HH. *The leſſer Protuberances called* Teſtes *or the Teſticles, which are Excreſcencies of the former.*

II. *The medullary Proceſſes which aſcend obliquely from the* Teſtes *into the Cerebel, and conſtitute part of either of its* Meditullium *or marrowy part of it.*

K. *The meeting of thoſe Proceſſes through another tranſverſe or croſs Proceſs.*

LL. *The beginning of the pathetick Nerves out of the meeting of the aforeſaid Proceſſes.*

MM. *A portion of the oblong Marrow lying under the aforeſaid Proceſſes and Protuberances.*

N. *The hole of the Ventricle or Cavity which is placed under the orbicular Protuberances.*

OO. *A portion of the annulary Protuberance ſent from the Cerebel, and embracing the oblong Marrow.*

PP. *The outmoſt and upper ſuperficies of the Cerebel.*

The Fourth Figure.

The Effigies of an humane Brain of a certain Youth that was fooliſh from his birth, and of that ſort which are commonly termed Changelings; the bulk of whoſe Brain, as it was thinner and leſſer than is uſual, its border could be farther lifted up and turned back, that all the more interior parts might be more deeply beheld together.

AA. *The border of the Brain lifted up, and very much bent back, which in its natural ſite, being knit to the oblong Marrow, nigh the Cerebel, did hide the* Nates *and* Teſtes.

B. *The border or inferior margent of the callous Body.*

CC. *The* Fornix, *with its two Arms, embracing the ſhanks of the oblong Marrow.*

DD. *The internal cavity or hollowneſs of the Brain reſulting from the folding together of its border about the oblong Marrow.*

EE. *The tops of the ſhanks of the oblong Marrow, or the ſtreaked or chamfered Bodies.*

FF. *The Chambers of the Optick Nerves.*

G. *The pineal Kernel, between which and the root of the* Fornix *the hole is, whoſe paſſage leads both to the Tunnel, and to the Ventricle lying under the orbicular Protuberances.*

HH. *The Protuberances called* Nates.

II. *The Protuberances called* Teſtes.

KK. *The medullary Proceſſes ſtretching out from the* Teſtes *to the middle of the Cerebel.*

LL. *The laid aſide Hemiſpheres of the Cerebel cut in two through the midſt, that the Trunk of the oblong Marrow may be the better ſeen, where its medullary ſubſtance branches out into the form of a tree.*

M. *The Furrow below the medullary ſtock, which being covered by the Cerebel, makes the fourth Ventricle in the form of a writing pen.*

NN. *The medullary Proceſſes which ſeem to be paſſages out of the oblong Marrow into the orbicular Protuberances.*

O. *The end of the oblong Marrow giving place to the ſpinal.*

CHAP. IV.

The Parts and ſome of the Contents of the ſeparated Skull unfolded.

IT is not our intent, nor will it be needful for us to delineate the figures and ſituation of the ſeveral Bones of the Brain-pan, or to deſcribe their various holes, which tranſmit the Trunks of the Veſſels like the hanging weights of a Clock. All theſe are well enough known; ſo that to treat of theſe Gates or Entries is ſuperfluous. Beſides alſo, by what means the Nerves, ariſing within the Skull with their ramification or branching forth, enters the dens and caverns of the Bones, ſhall be delivered particularly afterwards. Wherefore for the preſent our buſineſs ſhall be only to take notice of ſome things, chiefly worth noting, concerning the ſanguiferous Veſſels paſſing through the Cuniform or Wedge-like Bone, not ſufficiently noted by others.

Among the various uſes and offices which the Cuniform or Wedge-like Bone yields to the Brain and its Appendix, it is not of the leaſt note or moment, that it tranſmits the Carotidick Arteries, not without a certain mechanical or artificial proviſion; and that in the middle way, by which they muſt paſs, it contains the pituitary Kernel, and ſometimes the wonderful Net. Each of theſe deſerve conſideration; the more, for that in divers Animals they are after a different manner; and becauſe it is much controverted among Phyſicians concerning their frame and uſe. But we will firſt ſpeak of the pituitary Glandula, becauſe this part, being placed higher, is obſervable to Anatomical Inſpection before others.

The pituitary Glandula or ſnotty Kernel is hid within a proper Cell or ſtall, made hollow in the middle of the Wedge-like Bone, being ſhut up in the Cheſt ſometimes more ſtrictly, ſometimes more looſly: For in a Dog, Cat, and ſome other Creatures, ſticking to the Tunnel, it is pulled away together with it when it is removed; and then its bulk conſiſts of two Glandula's or Kernels diſtinct among themſelves, and eaſily to be ſeparated one from another. But in a Calf, Sheep, Hog, and many others, it is ſtrictly included on every ſide, except where it admits the Tunnel, and clothed with the hard *Meninx* or *dura Mater*, and with its coverings ſhut up between the cavity of the Bone. Beſides, in theſe, its frame or ſubſtance ſeems but one and undivided, though, in truth, it is made up of a ſubſtance which is of a twofold nature or kind.

This Glandula is found in all perfect Creatures; for Man, all four-footed Beaſts, yea Fowl or Fiſhes are provided or endued with it: from whence we may conclude it to have ſome neceſſary uſes in the Brain. But as to its quantity or bigneſs, its proportion is various in divers Animals, according to the bigneſs of the head and body wherein it is; becauſe in a Lamb it is greater than in a Man or Dog; alſo its bulk in a Horſe is leſſer than in an Ox. But the reaſon of this difference ſeems to conſiſt in this chiefly, for that the pituitary Glandula in ſome, reſpects the bulk of the brain only laid upon it, and in others both the brain and the Carotidick Arteries aſcending near it; and ſo as it hath a reſpect to both theſe together, or only to one, its ſubſtance or bulk is either greater or leſſer. For truly in ſome Animals the Carotidick Arteries being dilated within the Skull, are preſently divaricated into Net-like infoldings, and from thoſe infoldings many ſhoots of the Veſſels every where enter this Glandula, and are interwoven into its ſubſtance. Further, becauſe this Infolding of the Veſſels, called the wonderful Net, is found very large in ſome, and in others very ſmall; therefore this Kernel, for as much as it admits from theſe, few branches, and from thoſe far more, and in ſome other Animals ſcarce any ſhoots from the Arteries, anſwers to this divers diſtribution of the Veſſels, with the various proportion of its bulk. Becauſe it is obſerved in ſome Animals, as chiefly in a Man and a Horſe, that this wonderful Net is wholly wanting; and whereas in ſuch, either Artery is carried about by a long compaſs between the receſſes of this bone; from its trunk in a man ſometimes one or two ſhoots, ſometimes none, are carried into the pituitary Kernel; alſo in an Horſe fewer branches enter into it, and ſo its bulk in theſe becomes leſſer.

But in very many other Animals (eſpecially thoſe who have the wonderful Net) it may be proved, beſides ocular inſpection, alſo by this Experiment, that many ſanguiferous Veſſels enter this Glandula; for if an inky liquor be ſquirted into the Carotides with a Syringe, the exterior part of the Glandula, that is interwoven with the blood-carrying Veſſels, will be very much dyed with a black colour. Wherefore without doubt, it may be thought, that this Glandula doth receive into it ſelf the humors, to wit, flowing into it from the Tunnel in all kind of living Creatures, and in ſome from the branches of the Carotides. Yet by which way theſe humors are carried away again, doth not ſo plainly appear; for we affirm, with the moſt Learned *Schneider*, that they do not at all fall down into the Palate through the holes of the under-lying bone. Yet in the mean time, we ſuppoſe thoſe holes to be only made to procure lightneſs to the bone; becauſe in thoſe Animals, which have the greater pituitary Kernel, thoſe holes in the bone are more and larger: further, I have often found Veſſels or Chanels to be contained between thoſe holes; and when I had injected Ink within the

the great hole of the ſame bone in a Calf, the black liquor preſently entred the leſſer Veſſels ſubject to the bone, and at laſt the Jugular Vein. And by this Experiment chiefly we conjecture concerning the office and duty of this Glandula; of which we ſhall ſpeak more fully hereafter, when we inquire into the uſe of this and the Tunnel.

Nigh to either ſide of the pituitary Kernel, if the *dura Mater* be opened, the Carotidick Artery lyes ſtretched out upon the wedge-like bone, about the length of an inch: for as this Artery riſes up below the Turky-Chair, ſometimes higher, ſometimes farther within the Skull; the ſame being preſently bent in from its firſt aſcent, goes in under the *dura Mater* till it comes to the anterior border of the ſame Chair; where again being intorted, and being ſent forth upwards with a certain compaſs, it perforates the hard *Meninx*, and is carried ſtraight towards the Brain. So this Veſſel with its double aſcent and crookedneſs (to wit, above the Baſis of the Skull, and then above the hard Meninx, together with its ſituation, ſtretcht out in length under the ſame) repreſents in moſt the letter ↄ, inverſed; but in a man (as ſhall hereafter be more largely ſhewn) its ſite, by reaſon of the longer tract of the Veſſel and its greater curvature, repreſents the ſame letter double after this manner ↄ, ↄ.

The Carotidick Artery in all Animals aſcends obliquely within the Skull, but as to its ſite or protenſion nigh the pituitary Glandula, it is not after the ſame manner in all: for in a Man paſſing through the Canal-bone, peculiarly ingraven by it, with a ſingle Trunk, it lyes every where ſtretched out at length; and out of this Trunk it ſends forth ſometimes, though not always, ſome ſhoots to the pituitary Glandula. Alſo in a Horſe, its Trunk is ſingle; but where it firſt ariſes within the Skull, either Carotides, through the croſs branches ſent from one ſide to the other, before they perforate the *dura Mater*, communicate among themſelves. And as in moſt other living Creatures, the Artery, however before branched forth, yet being made one ſingle Trunk, goes into the Brain; in a Horſe either Carotick Artery being parted in two, ſends forth upwards two branches, ariſing from the *dura Mater*, in two diſtinct places.

In a Dog, Fox, Sheep, Calf, Stag, and many other four-footed Beaſts, either of the Carotides, whilſt hid within the Skull under the *dura Mater*, being divided into ſmall ſhoots, and complicated with other Veſſels, to wit, both Veins and nervous Fibres, conſtitutes the Net-like infoldings; which infoldings, being ſtretched out on either ſide of the Turky Chair, fill the cavity there exiſting; then after manifold divarications of all the Veſſels, ſome arterious ſhoots being diſintangled from the others, and again united, grow together into one Trunk, which boring thorow the *dura Mater*, paſſes ſtraight into the Brain.

The aforeſaid infolding is, commonly called the wonderful Net, and that deſervedly, for there is nothing in the whole fabrick of the animal Body more worthy of admiration; in which, beſides the arterious little branches which proceed from either of the aſcending Carotides, the veinous ſhoots, though fewer, meet with thoſe deſcending from the inward Jugular branches; and both kinds of Veſſels being divided into ſmall ſhoots, like a bundle of twiſted ſilk, are variouſly folded together; which complications of the Veſſels however are ſuſtained by the nervous Fibres, ſupplied from the greater Trunk of the fifth pair of Nerves. The aforeſaid infolding of the Veſſels or wonderful Net in ſome Animals is far greater, and contains much more divarications of the Veſſels than it hath in others; for in a Calf, Sheep, Goat, which are fed with graſs, its frame is larger than in a Dog, Cat, and other fleſh-eating and hotter Brutes. Further, it is obſervable, where the wonderful Net is greater, that the infolding of one ſide is ingrafted into the infolding of the other oppoſite ſide, and that from both, many more ſhoots of the Veſſels do enter into the pituitary Kernel; ſo indeed, that if you ſhall inject Ink into the Trunk of the Artery below the Skull, the Veſſels on either ſide, or the infoldings, will be dyed with the ſame tincture, and the black liquor will flow out of the Trunk of the oppoſite Artery.

In truth we have often ſeen this kind of Experiment repeated. Let the Carotidick Arteries be laid bare on either ſide of the *Cervix* or the hinder part of the Head, ſo that their little Tubes or Pipes, about half an inch long, may be exhibited together to the ſight; then let a dyed liquor, and contained in a large Squirt or Pipe, be injected upwards in the trunk of one ſide, after once or twice injecting, you ſhall ſee the tincture or dyed liquor to deſcend from the other ſide by the trunk of the oppoſite Artery: yea, if the ſame be more copiouſly injected towards the Head, from thence returning through the Artery of the oppoſite ſide, it will go thorow below the *Præcordia*, even to the lower Region of the Body; when in the mean time, little or nothing of the ſame tincture is carried thorow the outward and greater Jugular Veins. Then the Head being opened, all the Arteries, before the entrance of the Head, and the Veins of the ſame band with them, will be imbued with the colour of the ſame injected liquor. Further, in the Veſſels which conſtitute the wonderful Net, and which cover the Baſis of the Brain, ſome foot-ſteps of the ſame tincture will appear. But that this liquor doth deſcend ſo plentifully by the oppoſite Artery, and not by the Jugular Vein, either aſſociate or oppoſite, the reaſon is, becauſe it cannot enter thoſe Veins, unleſs the region of the whole Brain, being firſt paſſed thorow, it had entred the boſom; but the liquor being plentifully injected, could not ſo ſuddenly paſs through the very ſmall Veſſels covering the Brain: wherefore rather than the force ſhould be carried to the Brain by the violent impulſe of the liquor, it returning from the injection, and otherwiſe threatning a flood to the Brain, finds the

way

way of receding alſo by the oppoſite Arteries, for that end, both before they enter the Brain, and after they have entred it, communicating among themſelves. And here we cannot ſufficiently admire ſo provident (and to be equalled by no mechanical Art) a diſpenſation of the blood within the confines of the Brain. For in as much as the Carotidick Arteries do communicate between themſelves in various places, and are mutually ingrafted; from thence a double benefit reſults, though of a contrary effect: becauſe by this one and the ſame means care is taken, both leſt the brain ſhould be defrauded of its due watring of the blood, and alſo leſt it ſhould be overwhelmed by the too impetuous flowing of the ſwelling ſtream or torrent. As to the firſt, leſt that ſhould happen, one of the *Carotides* perhaps being obſtructed, the other might ſupply the proviſion of both; then, leſt the blood ruſhing with too full a torrent, ſhould drown the chanels and little Ponds of the brain, the flood is chaſtiſed or hindred by an oppoſite Emiſſary, as it were a Flood-gate, and ſo is commanded to return its flood, and haſte backward by the ſame ways, and to run back with an ebbing Tide.

By this kind of proviſion the Arteries about to enter the Brain are provided: yea, and the paſſages of the Veins, deſtinated for the returning of the blood from thence, ſeem alſo to be diſpoſed with a wonderful artifice. For when the anterior boſoms transfer their load into the two Laterals, which are the poſterior, and they themſelves end in the Jugular Veins, it is obſerved, that thoſe latter boſoms have furrows or cavities inſculped whereby they may ſettle or reſt upon the hinder part of the Head; and when as either boſom, through a proper hole, being about to go into the Jugular Vein, ſlides out of the Skull; nigh that hole, in the outward part of the Skull, a round and ample den is made hollow, and covered over by the extremity on either ſide of the ſame boſom, inlarged into a greater capacity, to the end, that the blood, whilſt it ſlides forth out of the Head with a full torrent, ſhould not ruſh into the Veins with too rapid and vertiginous an influx, and ſo make a forcible entry on the Heart it ſelf, therefore it hath here a diverſion large enough, in which eſtuating or boiling up, till a more free and open ſpace may be granted to its courſe, it may be ſtaid without any trouble. Certainly there can be nothing more artificial thought upon, and that can better argue the Providence of the great Creator, than this fit or convenient diſpoſition of the blood in the brain, and without it, and the way of its reciprocation in divers Animals, accommodated to the neceſſity of every one. And laſtly, in the diſſection of Beaſts, other miracles of the ſame nature happen, whereby ſhewing the Finger and Divine Workmanſhip of the Deity, a moſt ſtrong and invincible Argument may be oppoſed to the moſt perverſe Atheiſt.

The Fifth Figure.

SHews the interior Baſis of an humane Skull; where is ſhewn after what manner the Veſſels of every kind cut off from the Brain, and about to go out of the Skull, are hid or laid up under the dura Mater.

A. *The hollowneſs of the Bone of the Forehead.*

B. *The cloſe or mound of the Cribriform or Sieve-like Bone.*

CC. *The mammillary Proceſſes, which are much thinner, and endued with a leſs open cavity, than in four-footed Beaſts, endued with a more excellent ſenſe of ſmelling.*

DD. *The Optick Nerves, being far ſeparated, go out of the Skull otherwiſe than in moſt brute Beaſts.*

E. *The pituitary Glandula or Kernel with the top of the Tunnel inſerted into it.*

FF. *The Carotidick Arteries ſhewing themſelves nigh its ſides.*

GG. *The moving Nerves of the Eyes going out of the Skull.*

HH. *The pathetick Nerves, hid under the* dura Mater, *go out from the Skull at the ſame hole with the former.*

II. *The fifth pair of Nerves hid under the* dura Mater.

KK. *The ſixth pair ſtretched forth under the* dura Mater, *and go out alſo at the ſame hole with the third and fourth pair.*

CHAP. V.

The Brains of Fowls and Fiſhes deſcribed.

WHat hitherto we have ſhewn concerning the deſcription of the Brain and its Appendix, we chiefly owe to the obſervations made of the diſſection of the Heads of a Man and of four-footed Beaſts. We ſhall now proceed to the commenting upon theſe Obſervations; to wit, that we may endeavour, from the fabrick rightly conſidered of the parts of the Brain, ſo deſcribed, to erect their offices and uſes, and ſo to deſign the government of the animal Function: But becauſe a compared Anatomy may yield us a more full and exact Phyſiology of the Uſe of Parts; therefore before I enter upon this task, it will ſeem worth our labour to inquire into the Heads of ſome other Animals, to wit of Fowls and Fiſhes.

We have already hinted, that the Brains of Men and of four-footed Beaſts, were alike in moſt things; and alſo that the contents in the Heads of Fowls and Fiſhes being far different from both the former, yet as to the chief parts of the Head, are found to have between themſelves an agreement. The kinds of either Animals being coetaneous, and as it were Twins from the Creation of the World, do teſtifie their affinity in nothing more than in the fabrick of the Brain. That it is ſo in Man and four-footed Beaſts plainly appears already: we ſhall now ſee if that the Anatomy of Fowls and Fiſhes will ſhew us any thing worthy of note.

That we may begin with Fowls; the covering of the Skull being taken off, the hard *Meninx* or Membrane embraces ſtrictly the bulk or mole contained within. In the midſt of it, where the brain is divided into two Hemiſpheres, it hath a boſom ſtretched out at length, which notwithſtanding, no *Falx* (or Scythe) being let down between the interſtices, is inſerted leſs deeply in the brain; then, where this Membrane diſtinguiſhes between the Brain and Cerebel, two lateral boſoms are formed. Beſides in Fowls there is a fourth boſom, which hath its place a little more backward than in men or four-footed beaſts; for a little below the pineal Kernel a hollow and ſmooth proceſs of the hard *Meninx* is ſent down upon the ſhanks of the oblong marrow, where preſently it is divided into two branches, on either ſide whereof it it ſends forth one upwards into the cavity between the ſtreaked Membrane and the Hemiſphere of the brain, planted in the hinder part of the brain.

This ſuperior Membrane or hard *Meninx* being cut off, and ſeparated round about the *Pia Mater*, appears very thin, which is not, as in man or other perfect Creatures, marked with ſuch frequent infoldings of the Veſſels; but this moſt ſubtil *Meninx* being made of a texture of Fibres, only clothes, and every where intimately binds about the even and plain ſuperficies of the brain contained within, and wholly deſtitute of turnings and windings about.

The fabrick of the brain in Fowls is otherwiſe than in man or four-footed beaſts: for beſides that in its compaſs the inequalities and the turnings and windings are wholly wanting; alſo more inwardly, the callous body and the *Fornix*, as alſo the chamfered bodies, which we deſcribed before, are all lacking: and beſides, the ſubſtance of the Brain it ſelf is figured after another manner. That theſe may the better

be

be beheld, make the diſſection of the Brain of a Gooſe or a Turky-Cock; and the Membranes being cut off, by preſſing lightly the fiſſure or cleft of the Brain, you may divide the middle of it one from another, and go forward to ſeparate it, till you come to its boſom, in which place are two marrowy bodies, which being ſtretched out like Nerves, connect the Hemiſpheres one to another. Either ſide of the *Interſtitium* or the ſpace between, is clothed with a whitiſh Membrane, which is marked with ſtreaks or beams, lying or running from the whole compaſs or circumference, to the lower corner; and theſe ſtreaks concenter about the inſertions of the medullary bodies. Then, if this Membrane be cut, in either Hemiſphere of the Brain there will appear underneath a cavity, which goes under the whole ſpace, from the ſide of the *Interſtitium*, and for a great part, the hinder region of the Brain, and is arched or chambered with that ſtreaked Membrane. Either cavity or hollowneſs, about the bottom, is opened into an intermediate or common paſſage, which lies open to the Tunnel; and from either ſide of this paſſage the ſhanks of the oblong Marrow are ſtretched out, to which, on either ſide, the Hemiſphere of the Brain is hung by two medullary bodies; to wit, one marrowy or medullary body goes out from the mole or ſubſtance of the Brain lying under the Ventricle, the other from the ſtreaked Membrane covering the Ventricle. From theſe two, placed on either ſide, the medullary bodies being ſtretched out croſswiſe, like Nerves, joyn the two Hemiſpheres of the Brain to one another. Beſides, theſe two growing together on either ſide, fix either Hemiſphere of the brain to the ſhanks of the oblong marrow.

So the Figure of the Brain in Fowl, if you compare it with the Brain in men and of the more perfect four-footed Beaſts, ſeems to be as it were inverſed. For as in theſe the Cortical part is outward, and the medullary laid under it; ſo in Fowls, the lower frame of the Brain, which conſiſts of a thick and cloſer ſubſtance, is inſtead of the *Cortex* or Shell; but the outmoſt and upper Membrane, chambering the Ventricle, appears medullar or marrowy above any other part. Moreover, the Ventricles in the Brains of a Man and four-footed Beaſts are beneath, and near the bottom; in Fowls, above and nigh the outward border. The reaſon of this difference ſeems to be, becauſe placed in a more perfect brain, ſuch as is in Man and four-footed Beaſts, the animal Spirits have both their birth and exerciſe; *viz.* they are procreated in its Cortical or ſhelly part, and in its medullary, which being large enough, lyes under this, they are circulated and variouſly expanded for the acting of their faculties. But truly in the Brain of Fowls there is ſpace enough for the generation of Spirit, but for their circulation there is ſcarce any left: to wit, the Brains of Birds ſeem not to be much poſſeſſed with the gifts of phantaſie or memory: yea it is thought, that the Spirits begotten in the Brain are exerciſed chiefly in the oblong Marrow for the preſerving the animal function; for there, as we ſhall ſhew anon, the medullary ſubſtance, which is inſtead of the callous body, conſiſts; and like the ſtreaked bodies in others, in theſe are ſtreaked Membranes, through which the Spirits, procreated in the Brain are carried, without any order there, forthwith into the oblong Marrow: but becauſe the Spirits, begot in the brain, ought to lay aſide a ſerous excrement; therefore the Ventricles from the complicature of the ſtreaked Membrane upon the keel or lower part of the brain, and on the oblong Marrow it ſelf, do ſerve conveniently enough for this buſineſs. Notwithſtanding, becauſe in the Brains of Fowls, the *Fornix* is wholly wanting, there are only two anterior Ventricles; between which, the Choroeides infolding is ſtretched out; the veinous portion whereof, as was but now ſaid, ariſes a little lower from the fourth boſom; but the Arteries aſcending, come from either ſide of the oblong marrow.

Nor is there a greater heterogeneity or difference of conformation in the Brain it ſelf of Fowls, than in the oblong Marrow from the ſame in men and four-footed Beaſts. For in the firſt Section, from whence the Optick Nerves ariſe, two noted protuberances grow to either ſide. Theſe are much greater in proportion than the orbicular prominences in the more perfect Creatures; ſo that they ſeem another additional Brain: either of them of a white colour, and purely marrowy, is hollow within; ſo that in theſe kind of Animals are found two Bellies or Ventricles in the Brain, and as many in the oblong Marrow. And ſeeing in theſe, as in all other Animals, a cavity is put under the Cerebel, the Ventricles in the whole Head differ as well in number as in figure and poſition.

In the middle of the medullary Trunk, to wit, where thoſe prominences grow to its ſides, the Chink, leading to the Tunnel is cut, but into it the aperture of either Ventricle gapes or opens, that it is not to be doubted, but that the ſeroſities heaped up there, are ſent out by that way. Moreover it is likely, that theſe hollow and medullary prominences in Fowls ſupply the courſe of the callous body, to wit, in which the animal Spirits are circulated for the exerciſing their Faculties: becauſe in the Brain the ſpace is ſo narrow, that the Spirits cannot be produced and circulated together within its confines. Further, as in Fowls, the uſe of the animal Spirits is required for the act of the ſenſitive and loco-motive faculty, more than for phantaſie or memory; certainly the chief place where they may meet and be exerciſed, ought to be placed rather in the oblong Marrow than in the Brain.

The Carotidick Arteries, which carry the blood to the brains of the greater Birds, are ſo ſmall, that there is no proportion of theſe to the ſame in man and four-footed beaſts. Their Trunks being carried within the Skull, aſcend without any branchings into net-like infoldings, after the ſame manner as in other Animals, nigh to the pituitary Glandula, and paſs right into the brain, and diſtribute ſome ſmall ſhoots of the Veſſels both to its exterior compaſs, and through its inward receſſes. But in truth, the brains of Birds are watered with a very ſmall portion of blood, in reſpect of other living Creatures; becauſe, where the fancy or imagination is little exerciſed, there is not much blood required for the refreſhing the animal Spirits.

Fowl

Fowl (otherwiſe than ſome affirm) have both the mammillary proceſſes, and the Cribrous or Sieve-like bone. For the anterior productions of the brain being highly extenuated and involved with the *Dura Mater*, ſtretching out almoſt to the middle part of the bill, are inſerted into the triangular bone, which hath a double boſom, diſtinguiſhed between with a thin mound or pale. But theſe proceſſes being dilated within the boſom of the aforeſaid bone, and in Bladders full of clear water, which are very like the mammillary proceſſes in a Calf, full of clear water. Beſides, as out of the fifth pair of Nerves a noted branch on either ſide paſſing through the ball of the Eye, enters into the cavern of the Noſtril, a ſhoot of it being ſent out of the Trunk, is beſtowed to the very Orifice of the Noſtrils; in the mean time, both the greater Trunks, compaſſing about the Cribrous bone, meet together, and preſently going one from the other, and being carried to the end of the bill, are diſtributed into the palate. After this manner Fowls, even as men and four-footed beaſts, are furniſhed with a peculiar organ of ſmelling, to wit, with a double mammillary proceſs; and beſides, they have within the Noſtrils additional Nerves out of the fifth pair, by whoſe action and communication of branches into other parts, and among themſelves, ſo ſtrict an affinity is contracted between the ſmell and the taſte. The other pairs of Nerves are almoſt after the ſame manner as in men and four-footed beaſts. In like manner we alſo obſerve, that there is no great difference as to the Cerebel and the other portion of the oblong marrow; between Birds and the other Animals we have already conſidered on; unleſs that the orbicular prominences before the Cerebel, and the other annulary under it, meeting within them, are both wanting in Fowls; indeed theſe latter ſeem not at all to be required; but inſtead of the former, they are eaſily ſupplied from the hollow medullary prominences, ſuch as we have ſhewn to be in Fowls.

And theſe are what are chiefly worth noting to be found in the brains of Fowls. We have already mentioned, that there is a certain likeneſs between theſe and Fiſhes as to the moſt parts of the head; wherefore it will ſeem to be to the purpoſe, that here for a concluſion we ſhould ſay ſomething of the brain of Fiſhes. Firſt, we ſhall obſerve, that as the heads of Fiſhes, in reſpect of the whole body, are greater than of any other living Creatures, yet they contain in them leſs brain than others. For two little moles or ſubſtances, placed before, ſuſtain the whole place of the brain, properly ſo called; out of theſe, two ſignal ſmelling Nerves proceed, which are carried by a long and ſtraight journey to the holes made hollow, out of either ſide of the mouth, and which are inſtead of noſtrils: and this is ſingular to Fiſhes. Moreover, we advertiſe concerning the Optick Nerves, that they, as in other living Creatures, inclining mutually one to the other, are not however united, unleſs perhaps towards the ſuperficies; but they are croſſed, and a Nerve ariſing from the right ſide of the oblong marrow, is carried into the left Eye, and ſo on the contrary: ſo indeed, that the viſory rays have their refraction, not only in the Eye, but within the very bodies of the Nerves. The oblong marrow in Fiſhes, wholly after the like manner as in Birds, hath two ſignal protuberances hollowed within; and in truth, as to local motions, the Spirits in either ſeem to be exerciſed after the like mode. For as Fiſhes ſwim in the water, ſo the flying of Fowls or Birds ſeems a certain kind of ſwimming in the Air. Further, in theſe 'tis obſervable, there are the pituitary Kernel, the Tunnel, and the Carotidick Arteries as in other Animals; alſo many pairs of the Nerves have the ſame origines and diſtributions, excepting that the hearing Nerves are here wanting; although *Caſſerus Placentinus* attributes this gift to the ſmelling Nerves. The figure of the Cerebel is the ſame as in more perfect Animals. Beſides, what we have remarked concerning the wandring pair of Nerves in man and four-footed beaſts; to wit, many fibres of it ariſing together, the trunk of the Nerve from the ſpinal marrow comes to them: in like manner the ſame is in Fiſhes. But to deſcribe them all further is needleſs; for the reſt, as thoſe which are proper to them only and Birds, as alſo thoſe which they have common with Fowls and the more perfect Animals, may be eaſily known, partly out of the peculiar ſimilitude with birds, and partly out of the univerſal Analogy of all. Therefore we will now philoſophiſe upon the Uſe and Action of the Brain and its Parts, and of its Appendix, together with the whole œconomy of the animal Function: where in the firſt place, we will inquire into the offices of a more perfect Brain, ſuch as of man and four-footed beaſts; and alſo ſecondarily and collaterally we ſhall explain the Offices and Actions of a leſs perfect Brain, and of its Parts, ſuch as that of Fowls and Fiſhes.

CHAP. VI.

Of the Offices of the Brain and its Parts: where first of all the Uſes of the Skull and the hard Meninx or Dura Mater *is treated of.*

THE Poets feigned *Pallas* to be formed within the Brain of *Jupiter*, and from thence to be born. In truth, within the Womb of the Brain all the Conceptions, Ideas, Forces, and Powerrs whatſoever both of the Rational and Senſitive Soul are framed; and having there gotten a ſpecies and form, are produced into act. Wherefore it will be worth our labour to inquire into theſe places, of the generation of theſe more noble faculties, and the firſt riſe and primitive beginnings of them, as alſo more curiouſly to conſider the divers parts of the Brain, or the Organs ſerving to their Generation: And I go about this part of my labour the more willingly, that I may by handling the thread of our diſſection again, bring all the Phænomena, before given to our inſpection and ſenſe, before the Eye of Reaſon, and to be again weighed by a more ſevere Examination of Diſcourſe; at leaſt thoſe things which ſeem to be of the greater moment, and chiefly worth taking notice of. Neither do we think here to heap up into a great Volume the ſeveral things worn out by the handling of others, and offered to common obſervation.

Therefore recollecting the Anatomy of the Brain, the firſt things to be conſidered are its coverings, to wit, the Skull, and the two Meninxes or Maters. Concerning the firſt it is obſerved, that all perfect Animals have an hard and bony Skull. A double reaſon for which may be given: Firſt, that the Head being deſtinated for the moſt noble uſe, might be protected with a more firm and not eaſily penetrable covering, as a natural Helmet, againſt the injuries of external ſtrokes; beſides ſecondly, as this is in the place of Armor, ſo alſo of a Cloiſter; becauſe the ſame covering the *dura Mater* within, may reſtrain and keep within the Brain the Effluvia's of the animal Spirits, leſt they ſhould too thickly evaporate, or in heaps. Further, as the Skull for theſe ends is made bony, the efficient cauſe are the ſaline Particles of the blood watering the brain, which being unprofitable to the interior work of the animal Spirits, and ſo to be ſent away outwardly, grow together thus in the circumference, and are congealed into a ſtony hardneſs: For indeed the blood being carried towards the Head, as it abounds very much in Spirit, ſo in Salt; its Particles highly volatile, being joyned to the Spirits, are beſtowed on the brain; in the mean time, the ſaline little bodies, which are of a more fixed nature, being thruſt out into the circumference, from the Spirit implanted in the Brain, conſtitute the ſtony Skull, as it were a bubble covering incloſed wind.

Within the hollow ſuperficies of the Skull, there appear many furrows and inequalities imprinted by the proturberances of the Veſſels; and we perceive frequently either border or plate of it to be perforated by the paſſing through of the Veſſels in ſeveral places: but the Arteries, ariſing in the exterior ſuperficies of the *dura Mater*, make theſe kind of little ditches through the concavity of the Skull. For when the whole ſubſtance of the brain is at firſt ſoft, and eaſily giving place, like Wax; the Arteries underneath it continually beating, as it hardens by degrees, eaſily imprint the marks of their tracts.

The figure of the Skull in four-footed beaſts is narrow and preſt down, but in man, the ſubſtance of whoſe brain is large, there is required a more capacious and almoſt ſpherical figure. For as God gave him an upright countenance to behold the Heavens, and alſo endued his brain with an immortal Soul, and fitted for the ſpeculation of Heaven; therefore his face is erect or lifted up; ſo the brain it ſelf is placed in a more eminent place, to wit, above the Cerebel and all the Senſories. But in Brutes, and ſuch whoſe faces are prone towards the Earth, and have a brain unfit for ſpeculation, the Cerebel, however ſerving to the more noted action and office of the Præcordia, is placed in the higheſt ſeat to which the mole of the brain is ſubjected. Beſides, ſome organs of the Senſes, to wit, the Ears and Eyes, if they be not ſuperior, they are placed at leaſt equal to the brain. In an humane Head, the Baſis of the Brain and Cerebel being placed nigh together, yea of the whole Skull, is made parallel to the Horizon; whereby it comes to paſs, that there is leſs danger for any portion of the head to be jogged here and there, or to be moved out of its proper ſeat; But in four-footed beaſts, who go with an hanging down head, the Baſis of the Skull makes a right angle with the Horizon; wherefore the brain being ſubjected, the Cerebel is put in the higheſt place; ſo indeed, that this ſeems leſs ſtable, and that it may ſhake, or be moved from its ſeat. However againſt this inconvenience, leſt a frequent concuſſion of the Cerebel might induce a ſinking down or loſs of the Spirits, or irregularities about the Præcordia, in ſome it is taken care of by a wonderful artifice of Nature; for as in all the frame or ſubſtance of the Cerebel is moſt ſtrictly bound faſt together by the *Dura Mater*, beſides in ſome it is ſtaid by a bony fence; but in others, as in a Hare, Rabbet, and other leſſer Brutes, a certain portion of the Cerebel is included on either ſide by a ſtony bone, and ſo by this double hold its whole bulk or ſubſtance is firmly tyed to the Skull. Concerning the chief bones of the Skull, *viz.* the Cuniform or Wedge-like bone, the Cribrous or Sieve-like bone, and the auditory or hearing Organ, they ſhall be ſpoken of in their proper places, when we come to treat particularly of the Ventricles

Ventricles of the Brain, and of the Senſes to which theſe bones ſerve. We ſhall paſs next to the hard *Meninx* or *dura Mater*.

The *dura Mater* or hard *Meninx*, formed of a double kind of Veſſels and Proceſſes, bears alſo a double Aſpect, and ows part of its office to the Skull, that is about it, and part to the *Encephalon* contained within it. The exterior proceſſes of this Membrane are inſinuated within all the boſoms and cavities of the Skull; to ſome whereof they are a covering and defence, but to others they impart a ſenſible force, which manifeſtly appears in the Sieve-like bone, through whoſe holes the fringes of this Membrane paſſing, conduce ſomething to the ſenſe of ſmelling. Alſo the productions of this, lying over the receſſes and caverns of the Wedge-like bone, fortifie the ways for the entrance and coming out of the Veſſels. The interior proceſſes of the *dura Mater*, which belong to the Head, divide and diſtinguiſh between the parts of the Brain and Cerebel; and in thoſe places the *dura Mater* is very thick, leſt in any great concuſſion of the Head, theſe two ſhould be ſmitten one againſt another, and ſhould preſs one upon the other. Wherefore in Dogs (as we have already hinted) who are wont to run violently with their heads down, there is ſent down between theſe bodies a bony fence. In like manner in a Cat, Horſe, Fox, and many other Animals, from whoſe manner of living and uſe it is required, that they be moved with a ſwift motion, that bony fence, commonly called the Triangular Bone, is ſent down deeply between the Brain and the Cerebel; yea, and all the boſoms paſs through that bone in the holes curiouſly made hollow in it.

The Veſſels belonging to the *dura Mater* are either Arteries, that carry the blood thither; or they are Veins, which receiving from thence the ſuperfluous blood, and from the whole Head beſides, return it towards the Heart. As to the firſt ſort of Veſſels, on either ſide, two Arteries ariſing from the Carotidick Artery on the ſame ſide, before it comes to the Baſis of the Brain, are carried into the *dura Mater*: which notwithſtanding, only poſſeſſing the exterior ſuperficies or convex part, carry blood and juyce to this Membrane, alſo in ſome meaſure to the Skull and its coverings. As to the Veſſels carrying the blood back, this Meninx contains four, into which, as into a great Sea, all the Rivulets of the Arteries, ſerving the whole Head, do exonerate themſelves: to wit, there are obſerved in this Membrane four noted Cavities, commonly called Boſoms; which are diſpoſed after that manner, that, like Promptuaries or Store-houſes framed in ſeveral places, they receive the blood returning from every region and corner of the brain: For the third boſom, or the longitudinal, looks towards the anterior brain, the fourth towards its middle; but the firſt and ſecond admit the blood flowing back from the Cerebel and hinder part of the brain. Further, out of theſe the third and fourth disburden themſelves into the firſt and ſecond, and theſe at length transfer their burden into the Jugular Veins. On every ſide, from theſe boſoms, the leſſer Veſſels, *viz.* the chanels of the Veins are ſent forth, which going out nigh the interior or concave ſuperficies of the *dura Mater*, are preſently inſerted into the *Pia Mater*; and following its protenſion, being diſtributed through the whole compaſs, and all the interior receſſes of the brain and its Appendix within the Skull, and being complicated with the Arteries, receive the ſuperfluous blood, and carry it into thoſe greater cavities. That it is ſo, it plainly appears, becauſe if you ſquirt a liquor, dyed with Ink, into the Pipe of the Artery, that paſſing through the arterious ſhoots, and then the veinous, goes through at laſt into the boſoms.

Whilſt the blood, returning from the whole interior Head, is collected within thoſe boſoms, as with a full belly, it ſeems alſo in another reſpect to be of a very notable uſe; to wit, for the ſupplying of heat, requiſite for the diſtilling forth of the animal Spirits, as if it were a certain Chymical operation. For as much as the blood to be diſtilled, is contained in the Veſſels, interwoven into the *Pia Mater*, the ſuperiour Rivers diffuſed on every ſide through the *dura Mater*, the heat being brought to it like a *Balneum Mariæ*, flow about the under-lying blood, and ſo force out of it a moſt ſubtil Liquor into the ſubſtance of the Brain; or rather, the blood raiſing up heat within the boſoms, is like the fire of ſuppreſſion, which in the diſtillation by deſcent, is inkindled round about the Veſſel containing the matter to be diſtilled. For indeed the interior ſubſtance of the Brain, for that it is endued with plenty of Salt and very little Sulphur, is of a more frigid temper: wherefore, that from the blood watering its ſuperficies, the ſpirituous part may be ſtilled forth, and forced into its middle or marrow, the degree of the ambient heat ought to be made the more ſtrong, ſuch indeed, as the blood collected in the ample Eſtuaries of the boſoms, may eaſily afford. Further, as thoſe boſoms being diſtended with heated blood, are like a certain diſtillatory Bath; ſo the other Membrane of the *dura Mater* being ſtretched out about the whole Head, is like an impervious Alembick, which with its covering keeps within the ſpirituous breaths, that they may not be immoderately evaporated.

Concerning this Membrane there may yet be conſidered, with what motion or ſenſe it is endued. And as to ſenſe, 'tis not to be doubted, but that it hath it exquiſitely: For ſince all the Membranes have feeling, and owe that faculty to the afflux of the animal Spirits from the Brain, ſurely this Meninx, for that it is nearer and very much of kin to the Brain and its Appendix, ſo that it clothes very many Nerves going out of the Skull, it obtains a very accurate virtue of feeling: which thing alſo may be argued from the effect; becauſe the pains of the Head often proceed from the breach of unity excited in this Membrane. But that it hath motion, it can hardly be thought, becauſe it is tyed in very many places to the Skull; and yet it is probable, that the ſame may ſometimes, in ſome parts at leaſt, be contracted and wrinkled or drawn together: And certainly there is no doubt, that it is contracted and remitted in ſneeſing.

In like manner, when from an hurt of this a Vomiting or Convulsive motions follow in the *Viscera* or Members, this Membrane is the cause, which being somewhere contracted or divided, infolds with it self the substance contained within the same Convulsion or Spasm.

Concerning the motion of this Membrane, a curious mind may yet further consider its texture, and especially how it is within the cavities of the bosoms, and the *Interstitium* or separation of the Brain and Cerebel. For in these places are found many Fibres, or as it were greater or nervous cords or strings, such as we have observed to be variously stretched out in the Ventricles of the Heart. Within the bosoms, from the various processes of the Membrane, a cavity full of turnings and windings, and manifoldly divided, as it were with many little Cells, is constituted. This seems to be thus made, to this end, to wit, that the blood returning back from divers little rivers into the cavities of the bosoms, may be retarded by several obstacles, as it were little flood-gates; lest perhaps rushing too impetuously and by heaps, it might flow within this Sea with a vertiginous and inordinate motion. But there is observed, besides these intrications and little cells of this Meninx in the heads of four-footed beasts, that moreover in the whole cavity of the bosoms, very many cords, as it were Ligaments, are every where produced from one side to the other. The office of these is partly, that they may contain the sides of the cavity within their due ends of aperture and dilation, lest they should be distended above measure by the vehement rushing in of the blood, and so may press upon the substance of the brain. Yea the contexture of these whitish Fibres, which are met with, both within the cavities of the bosoms, and in this Meninx, going about the Cerebel, and distinguishing between it and the Brain, seems to intimate, that they serve also to some motion. For it may be suspected, that those strong Fibres, and as it were Ligaments, do sometimes contract, sometimes dilate, and variously draw the Membrane to which they are knit. From these kind of motions of the *dura Mater*, the blood flowing within the bosoms, may be variously agitated, and as occasion serves, sometimes hastened in its Circle, and sometimes restrained or hindred; for in many affections of the sensitive Soul, the blood being disturbed from its equal circulation, is sometimes precipitated by heaps and impetuously to the Heart, and sometimes detained from its nest longer, nigh the confines of the Brain. But that various whirl-winds of passions stir up such irregularities in the motion of the blood, the nervous parts implanted about the *Præcordia*, are in some measure the cause, which by contracting or dilating the same, variously moderate the course of the blood, yet so, that in the mean time, some part of this office is due from the brain it self, or at least to its Appendix. Indeed the brain it self wants motion; but the blood passing through its substance, for as much as it is poured wholly in this Meninx, and passes through its receptacles, is at the motion and beck of this Membrane, sometimes driven away from the brain, and commanded to succour the Heart, as in fear and great sadness, sometimes being hastened towards the brain, is for some time prohibited from flowing back, as in shame, indignation, and some other affections.

Truly, that these kind of interior processes of the bosoms, and as it were transverse strings or cords, do conduce to the more commodious reduction of the blood, we gather also from hence, that in working beasts, whose brain (because they feed and go with a prone and hanging down head) is in greater danger of an inundation of the blood, those processes are very big, for that they being successively contracted, may leisurely thrust out the blood, apt otherwise to stagnate by reason of the inclination of the head. Neither is it from the purpose to observe here, that these same Animals are always furnished, for that reason, with a greater wonderful Net: by which means indeed it is provided, that the blood may not too much invade the brain by heaps; as care is taken by the artifice but now described, lest the same should make too long stay in the brain, and so oppress its more weak frame.

Therefore in the last place, that I may recollect what I have said of the *dura Mater*, and rehearse its chief uses: First, It covers over the Skull within, and reaches to it somewhat of nourishment by the Vessels. Secondly, It is a covering to the whole head, and serves to distinguish its chief parts. Thirdly, It contains the Vessels designed for the reducing the blood from the whole interior head; which, in the mean time, by reason of the plenty of the blood contained in them, and the opportunity of their situation, administer requisite heat for the distillation of the Spirits. Fourthly, It provides ways for the admission and going out of all the Vessels within the Skull, and fortifies them; to which may be added, that it bestows on some of them their Coats, as shall be shewn anon. Fifthly and lastly, This Meninx being here and there contracted or divided by the animal Spirits variously moved, according to the passions of the Soul, or the necessities of Nature, stays the blood sometimes longer near the confines of the Brain, sometimes drives it forward from thence towards the *Præcordia*.

CHAP.

CHAP. VII.

Of the thinner Meninx or Pia Mater, *of its ſtretching out, as alſo of the Infoldings of the Veſſels every where interwoven with it.*

THE interior *Meninx* or *Pia Mater* is far thinner than the extetior, and conſiſts of a moſt ſubtle contexture of Fibres. This does not compaſs about the *Encephalon*'s ſuperficies as looſly as the *Dura Mater*; but embraces it ſo very ſtrictly, that it is very hardly ſeparated from it: beſides, it inſinuates it ſelf into all its turnings and windings and furrows, and clothes their inward parts. Further, this *Meninx*, although it be thin, yet being covered over throughout with the infoldings of Arteries and Veins, is interwoven with them, and ſo waters all the ſpaces of the Brain and Cerebel with innumerable rivers. For as the Region of either of theſe, eſpecially of the Brain, is full of turnings and windings, this Membrane in like manner grows to the deep furrows of the crankling turnings about, and alſo to the tops of the ridges; yea, the chief complications of the Veſſels are ſtill placed in the vallies, as if they were there hid in regard of their ſafety. Neither doth this *Meninx* only cover the gapings of the turnings and windings about; but alſo gathers together the tops or heights of all their interſtices or places between, and knits them together, and ſo makes the whole ſuperficies of the Head plain, globous, and as it were like the World.

That the diffuſion of this wonderful Membrane into all the turnings and windings of the Brain, and the diſtribution of the Veſſels through thoſe moſt intimate receſſes, may be the better beheld; let the head of a man, or of a brute beaſt that dyed of the Dropſie, be opened: For in ſuch, whoſe brain abounds with much moiſture, the little ſtays, whereby this Meninx is fixed to the ſubſtance of the brain, are looſned, ſo that the Membrane, with the infoldings of the Veſſels, may be eaſily drawn away, and pulled off almoſt whole: which indeed being pulled off, the folds of the brain will appear naked: alſo the inſertions of the Veſſels every where into the more inward ſubſtance of the brain, may be perceived. But to a ſound and dry brain the *Pia Mater* ſticks ſo cloſely, that it can ſcarce be drawn away in any part, or ſeparated with a Penknife.

We have already ſhewn after what manner the Veins and Arteries (which creeping like Ivy, are knit into the *Pia Mater*, and variouſly interwoven into it) cover over with moſt thick little ſhoots, the whole compaſs of the Brain and Cerebel, and their Interſtices, the gapings of the crankling turnings and windings about, boſoms and cavities, and ſend forth every where ſmall ſhoots into the medullary ſubſtance; ſo that it is not to be doubted, but that the animal Spirits, being as it were ſtilled forth immediately from the blood, every where in the whole head, are received into the Pores and paſſages of the Brain and Cerebel. From whence it will be eaſie to aſſign the uſe or office of the *Pia Mater*, *viz.* Firſt, this Membrane clothes the univerſal parts of the whole *Encephalon*, and diſtinguiſhes them all one from another. For indeed, this lying over all the gapings and interſtices of the turnings and windings, is inſtead of a mound or fence, by which the animal Spirits are reſtrained every where within their proper cells and orbs of expanſion, nor are they permitted by this means to run beyond their bounds, and ſo confound the acts of the many Faculties. Then ſecondly, this Meninx ſuſtains all the blood carrying Veſſels, *viz.* both the Arteries and Veins, together with their manifold productions, and ſo affords a paſſage to the blood, by carrying it to and fro towards the brain.

Concerning theſe Veſſels, which are knit to this Meninx, and follow its ſtretching out into all parts, there are many admirable things to be met with, and highly worthy of note, the uſes and reaſons of which is our purpoſe to ſearch into.

As to theſe, we ſhall firſt obſerve, that theſe Arteries and Veins, otherwiſe than in any other part of the body beſides, not ariſing nigh one another, go forth as companions, but going forth from oppoſite ends, meet every where mutually, *viz.* the Arteries aſcend from the Baſis of the Skull, and by creeping through the whole, emit upwards ſhoots and branches, which are met by the Pipes of the Veins ariſing out of the boſoms, and carried downwards. By this means the rivers of the blood ſeem to be made equal every where in the Brain, *viz.* whilſt the ſmaller ſhoots of the Veins follow or match the greater branches of the Arteries, and on the contrary, the ſmall branches of the Arteries the Trunks of the Veins.

Secondly, We have already ſhewn, that theſe Veſſels are variouſly and very much ingrafted or inoculated among themſelves, not only the Arteries with the Veins, but what is more rare and ſingular, Arteries with Arteries; to wit, the Carotidick Arteries of one ſide, in many places, are united with the Carotides of the other ſide; beſides the Vertebrals of either ſide among themſelves, and are alſo inoculated into the poſterior branches of the Carotides before united. The joynings together of the Carotides, in moſt living Creatures, are made about the Baſis of the Skull under the *Dura Mater*, and that after a diverſe manner, in ſome communicated through the Veſſels of the Wonderful Net from one ſide to the other; in others (as in a Horſe we have obſerved with a certain admiration) the arterious chanel is produced

produced between the Trunks of the *Carotides*, whereby the blood may be carried from one ſide to the other, and ſo on the contrary. But beſides, between the *Dura Mater*, about the Baſis of the Head, the ſame kind of ingraftings of the Arteries are ſtill ſeen in man and all perfect four-footed beaſts.

The reaſon of theſe ſeems to be partly, that the blood to be carried from the Heart into divers Regions of the Brain, might be exactly mingled as to its parts and particles, before it come to the place deſigned. For the Torrent of the blood, becauſe divided into leſſer rivulets, is incident to languiſh in ſo long a circuit, and its Spirits to be depauperated, and laſtly it ſelf to grow cool; unleſs that various courſes of its *Latex* ſhould anew inkindle this vital flame about to be extinguiſhed or dye.

But there is another reaſon far greater than this of theſe manifold ingraftings of the Veſſels, to wit, that there may be a manifold way, and that more certain, for the blood about to go into divers Regions of the Brain, laid open for each; ſo that if by chance one or two ſhould be ſtopt, there might eaſily be found another paſſage inſtead of them: as for example, if the *Carotides* of one ſide ſhould be obſtructed, then the Veſſels of the other ſide might provide for either Province. Alſo as to the *Vertebral* Arteries, there is the ſame manner of proviſion made. Further, if both the *Carotides* ſhould be ſtopped, the offices of each might be ſupplied through the *Vertebrals*, and ſo on the other ſide the *Carotides* may ſupply the defects of the ſhut up *Vertebrals*.

After this manner, leſt there ſhould be wanting an afflux of the blood at any time in any part of the Brain, or its Appendix, within the Skull, there is care taken with ſingular Art: For as there are four diſtinct paſſages, and thoſe remote one from the other, of this *Latex*, if perchance three of them ſhould happen to be ſhut up, the blood being carried through one only, will ſoon ſupply or fill the chanels and paſſages of all the reſt. Which thing I have found by experience often tryed, not without admiration and great pleaſure. To wit, I have ſquirted oftentimes into either Artery of the *Carotides*, a liquor dyed with Ink, and preſently the branches on either ſide, yea and the chief ſhoots of the Vertebrals, have been dyed with the ſame tincture: yea, if ſuch an injection be ſometimes iterated by one only paſſage, the Veſſels creeping into every corner and ſecret place of the Brain and Cerebel, will be imbued with the ſame colour. Alſo in thoſe who have the wonderful Net, the Tincture or dyed Liquor being injected in one ſide, it will come through the Net like infoldings of the Veſſels in both ſides. Hence it plainly appears that there is a communication between the Veſſels watering the whole Head; and although every Artery is carried to one only Region, as its peculiar Province, and provides for it apart; yet, leſt any part ſhould be deprived of the influence of the blood, more ways lye open to every part by the ingraftings of thoſe veſſels; ſo that if the proper veſſels by chance ſhould be wanting in their office, its defect may preſently be compenſated by others neighbouring.

It is not long ſince we diſſected the dead body of a certain man, whom a great *Scirrhus* or hard Swelling within the *Meſentery*, growing at laſt ulcerous, had killed. When his Skull was opened, we beheld thoſe things belonging to the Head, and found the right *Carotides*, riſing within the Skull, plainly bony or rather ſtony, its cavity being almoſt wholly ſhut up; ſo that the influx of the blood being denied to this paſſage, it ſeemed wonderful, wherefore this ſick perſon had not dyed before of an *Apoplexy*: which indeed he was ſo far from, that he enjoyed to the laſt moment of his life, the free exerciſe of his mind and animal function. For indeed, Nature had ſubſtituted a ſufficient Remedy againſt that danger of an *Apoplexy*, to wit, the *Vertebral* Artery of the ſame ſide, in which the Carotidick was wanting, the bulk of the Pipe being enlarged, became thrice as big as both its Pipes on the other ſide: becauſe, the blood being excluded the Carotidick, adding it ſelf to the wonted proviſion of the Vertebral Artery, and flowing with a double flood into the ſame belly, had ſo dilated the chanel of that Artery above meaſure. This Gentleman, about the beginning of his ſickneſs, was tormented with a cruel pain of the Head towards the left ſide. The cauſe whereof cannot be more probably aſſigned, than that the blood excluded from the right Carotidick Artery, when at firſt it ruſhed more impetuouſly in the left, had diſtended the Membrane; and therefore the ſame diſtemper did afterwards vaniſh of its own accord, to wit, the ſuperfluous blood being derived through the *Vertebral* Artery.

Thirdly, Concerning theſe ſanguiferous Veſſels covering the *Pia Mater*, we obſerve, that the Arteries and Veins, whilſt they meet one another, going out from oppoſite ends, do not only transfer their burden immediately through the ſeveral branches or ſhoots, mutually ingrafted, as is wont to be done in other parts of the Body; but being variouſly complicated and interwoven, do conſtitute every where admirable infoldings, into which, for the moſt part, very ſmall and very numerous Glandula's or Kernels are inſerted. Which thing is ſeen, not only in the infoldings, which are called *Choroiedes*, (by which name, beſides thoſe which are found within the plicature or folding up of the Brain, we alſo intend others planted together behind the Cerebel) but theſe kind of infoldings of the Veſſels, with Glandula's ſowed between, are ſeen every where to be ſprinkled through the whole compaſs and interior receſſes of the Brain and Cerebel, and eſpecially between the gapings of their turnings and windings and interſtices. This is clearly manifeſt in a moiſter Brain, or in an Hydropical, where the very ſmall Glandula's, which otherwiſe are ſcarce to be ſeen, being intumified by the moiſture, are eaſily beheld. Moreover, from the aforeſaid infoldings, on every ſide implanted, little ſlender Veſſels, being every where ſent forth, enter the Cortical, and in ſome meaſure the medullary ſubſtance of the Brain and its Appendix, for if you ſquirt into the *Carotides* a black liquor, beſides the ſhoots of the Veſſels, which it dyes every where with the ſame colour, little blackiſh pricks will appear ſprinkled in the ſubſtance of the Brain. Further, if the

Brain

Brain of a living Animal be cut up, the live blood will ſpring forth both from its *Cortex* and medullary part. The reaſon and end of all which, if they be inquired into, it ſeems that theſe foldings of the Veſſels, being variouſly complicated with repeated windings about, as if they were little ſerpentine chanels hanging to an Alembick, through whoſe narrow ſtraits the blood paſſing with a long circuit, becomes ſtill more ſubtil and elaborated: to wit, its thicker part, being by degrees put off in its paſſage, or ſent away by the little branches of the Veins, and ſo at length the only pure and moſt ſpirituous blood, and it ſelf now ready to go into animal Spirits, is admitted within the Pores and paſſages of the Brain. But as the blood or ſanguinolent part is ſupped up by the Veins, ſo it's very likely the Serum or watry part is received by the Glandula's or Kernels interwoven in them. For it appears not for what other end theſe Arteries are every where beſet with ſo many Kernels, unleſs they ſhould lay up in them the ſuperfluous ſerolities. Between theſe infoldings there appear not any Nerves to be found, which may require any juyce or ſerous humor from theſe Kernels; and 'tis not yet found, whether theſe Lymphæducts or Water-carriers be accompanied with any Veſſel: wherefore it may be lawful to ſuppoſe, that whilſt the purer and ſpirituous part of the blood, being ſeparated from the reſt of its maſs, is ſtilled forth into the brain, the ſerous humidities are received by the Glandula's, which are numerous, and that they are for ſome time retained by them, till they may be ſent away into the Veins growing empty again.

Thus far we have beheld only the ſuperior branchings forth of the blood-carrying veſſels, which are every where interwoven in the *Pia Mater*; and their infoldings, which like the leaves of a Wood, or creeping Ivy, cover the exterior compaſs of the whole Head. But by what means, and as it were Chymical Artifice, theſe Veſſels do inſtil the animal Spirits into the Brain and Cerebel, and ſerve for the uſe of one another beſides, ſhall be told anon, after we have conſidered of the inferior Aſpect and next the ground of this moſt thick Wood, *viz.* the greater Trunks of all the Arteries, which are deſtinated for the Brain, where they paſs through the Skull, and ſhew themſelves beyond it.

CHAP. VIII.

Shews with what difference the Arteries in various Animals paſs through the Skull; alſo for what uſe the wonderful Net is made, and the reaſon of it.

THE Arteries deſtinated to the Brain, are four in number, *viz. two Carotides*, and as many *Vertebrals*. Concerning the former, we have already obſerved, that their Trunks paſs through the Wedge-like Bone, as it were with a mechanical proviſion; to wit, either Artery is ſo bowed and intorted in its aſcent, that the blood, before it can reach to the Brain by a repeated ſtopping of ſhores, or hindred by a certain let or impediment, might flow to it leſs rapidly and more ſlowly. But this is not effected after one and the ſame manner in all Animals: for although the aſcent of the Artery be oblique and intorted in all, yet in ſome, *viz.* in a Man and a Horſe, it being bowed about with a greater compaſs, ſtill enters, even to the Brain, with a ſingle and undivided Trunk: when in moſt other beaſts the ſame paſſes the Skull with a leſſer circuit, and ſliding preſently under the *Dura Mater*, diverſifies it ſelf there into Retiform infoldings, commonly called the wonderful Net. Therefore it ſeems to be to the purpoſe, that we inquire into the various reaſons of this difference.

In the firſt place therefore we ſhall advertiſe you: that the Carotidick Artery in a man enters a little more backward the Skull, than in any other Animal, *viz.* nigh that hole through which the lateral boſom ſlides out of the Skull about to be implanted into the Jugular Vein; for in the reſt, this Artery ariſes within the Skull under the end or acute proceſs of the ſtony bone. But in an humane Head, the ſame being carried about by a longer compaſs, (that the Torrent of the blood, before it comes to the border of the brain, might flow ſlowly and pleaſantly with a broken force) attains to the baſis of the Skull nigh the den made by the ingreſs of the lateral boſom; where being preſently intorted, it enters the proper Chanel inſculped in the Wedg-like bone, and for the greater aſſurance it is clothed beſides with a thicker additional Coat. This double defence ſeems to be given it, leſt the blood, boiling up too much, and whilſt it is carried violently towards the head, ſhould make a Whirlpool about the ingreſs of the Skull, to wit, where it begins to be wreathed about from its direct aſcent, and ſhould break by its flood the banks of the Belly, unleſs they were more firm. The Artery being ſlid out of the bony channel, lays aſide alſo its aſcititious or additional Coat; and now being well enough defended within the Skull, goes forward clothed only with its proper Coat, and creeps under the *dura Mater*, and being as it were depreſſed in the midſt of its paſſage into a valley, being immediately carried out again, it goes on till it comes to the head of the Turky Chair, where again being bent in and intorted, with a certain compaſs, it aſcends ſtraight, and boring through the *dura Mater*, is carried towards the brain. The Trunk of this *Carotis*, like a Meander, paſſing through the Skull with a very much bending way or paſſage, is aptly repreſented in the firſt Figure of the following Table.

If

If the reaſon of this kind of Conformation be inquired into, it eaſily occurs, that in an humane Head, where the generous Affections, and the great forces and ardors of the Souls are ſtirred up, the approach of the blood to the confines of the Brain, ought to be free and expeditious; and it is behoveful for its River not to run in narrow and manifoldly divided Rivulets, which would ſcarce drive a Mill, but always with a broad and open chanel, ſuch as might bear a Ship under Sail. And indeed, in this reſpect, a man differs from moſt brute beaſts, in which, the Artery being divided into a Thouſand little ſhoots, leſt it ſhould carry the blood with a fuller chanel, or more quick courſe than is requiſite, makes the Net-like infoldings, by which indeed it comes to paſs, that the blood ſlides into the Brain very ſlowly, and with a gentle and almoſt even ſtream. If that be true, as ſome affirm, that the wonderful Net alſo is ſometimes found in an humane Brain, I believe it is only in thoſe ſort of men, who being of a ſlender wit or unmoved diſpoſition, and deſtitute of all force and ardor of the mind, are little better than dull working beaſts in fortitude and wiſdom.

Secondly, The conformation of the Carotidick Artery in a Horſe, comes neareſt its ſtructure in a man for in this the Artery enters the Skull alſo lower, and with a greater compaſs than in other four-footed beaſts: which being paſſed, its Trunk being intorted, with a certain compaſs, and then a little depreſſed, goes forward whole to the ſide of the Turky Chair ſtill with a full and broad chanel; which truly ought to be made ſo, becauſe magnanimous and fierce forces are convenient for this Animal, born as it were for War and any dangerous attempts; and ſo there was need, that the blood might aſcend the Brain with a free and plentiful courſe, and (when occaſion requires) with a full Torrent. But though the blood paſſes through the Baſis of a Horſes Skull in the ſame undivided chanel, yet it ought not to come to the Brain it ſelf in one ſingle paſſage; becauſe the frame or ſubſtance of this in a Horſe being far weaker and colder than in a man, it might be overthrown and drowned by the blood ruſhing in by heaps: wherefore the great River of the Artery disburdens it ſelf by two Emiſſaries, and pours out its *Latex* at ſo many diſtinct places of the Brain. Further, as if by this means there were not yet ſufficient caution againſt the Deluge of the Brain, a tranſverſe or croſs chanel, as it were a diverſion, is formed between the chanels of either Artery; through which the blood, being ſtraitned for room, may go aſide, and flow and reflow from one bank or chanel to another, rather than oppreſs or overflow the Brain. Alſo beſides, certain ſhoots being ſent out from the Trunk of either Artery, are inſerted into the pituitary Glandula, the uſe of which is doubtleſs to ſeparate certain ſeroſities of the too watry blood, and to lay them up into that Glandula, whereby the reſt of the bloody *Latex*, to be carried to the Brain, becomes more pure and free from dregs. By what means the Carotidick Arteries, in the head of a Horſe, paſs through the Baſis of the Skull, is repreſented in the ſecond Figure of the following Table. I have not yet had the means to inſpect the brains of a Lyon or a Monkey; but there is reaſon to ſuſpect, that in theſe alſo the Carotides do paſs through the Skull with a ſingle Trunk. In a Sheep, Calf, Hog, yea in a Dog, Fox, Cat, and other four-footed beaſts, which I have hitherto opened, this Artery is devaricated into Net-like infoldings, which Veſſels, for what cauſes and for what uſes they are ſo made, we ſhall now inquire into.

Thirdly therefore, moſt other four-footed beaſts, different from a Man and a Horſe, have the wonderful Net adjoyned to the Carotidick Artery. In truth, this is met within ſo many, that common Anatomy hath aſcribed it to all Animals, and alſo to man it ſelf. In whom it is found, we obſerve, that the Artery, about to enter the Skull, is not carried about with ſo long a compaſs, but riſing up nigh the hinder part of the Turkiſh Chair, is preſently divided into ſmall ſhoots; yet ſo, as one little chanel is ſtretched right out, which the blood quietly running to, paſſes through without any ſtay, being carried ſtraight into the Brain: but from the ſide of this many rivulets are derived on every ſide, into which the blood impetuouſly aſcending, may be eaſily diverted. Theſe little rivers are partly ingrafted into the veinous paſſages of the ſame, and the Veſſels of the other ſide, and are partly carried into the pituitary Glandula, and partly a compaſs being fetched, are returned into the former chanel or belly of the Artery. That it is ſo, beſides naked inſpection, appears plainly by this Experiment. If below the Skull, an inky liquor be gently and by degrees injected into the Trunk of the *Carotis*, that paſſing through the ſtraight paſſage, is carried preſently into the Brain, nor does it dye the lateral infolded Veſſels with its tincture; but if this liquor be immitted continually and forcibly, preſently running into the folds, it will make black the Veſſels of the ſame and of the oppoſite ſide, alſo entring the hither part of the Glandula and its interior ſubſtance. If the uſe of theſe kind of infoldings of the Veſſels, or the wonderful Net be inquired into, I ſay, that it is made chiefly for theſe ends: *viz.* Firſt, that the Torrent of the blood being divided into ſmall rivulets, its more rapid courſe may be ſo far dull'd or broken, that it may be but leiſurely inſtilled into the Brain. For otherwiſe in labouring beaſts, who go with their hands hanging down, and have but a weak brain, the more free influx of the blood might eaſily overthrow the fabrick of the Brain, and ſpoil the animal Spirits. Secondly, the divarication of the *Carotides* into Net-like infoldings, hath another uſe of no leſs moment, to wit, that the more watry blood being (as it is its temperament in moſt Beaſts, and eſpecially in thoſe who are fed with herbage) before it be poured upon the Brain, might carry away ſome part of the ſuperfluous Serum to the pituitary Glandula, and inſtil the other part into the branches or ſhoots of the Veins to be returned towards the Heart. Thirdly and laſtly, for as much as the Veſſels on either ſide are mutually inoculated by this means, there is care taken both that the blood may be exactly mixed before it aſcends to the Brain, as alſo that more certain ways may be made for its paſſage: becauſe, if perchance an obſtruction ſhould happen in one ſide of the wonderful Net, the blood by that infolding being preſently

Fig. I

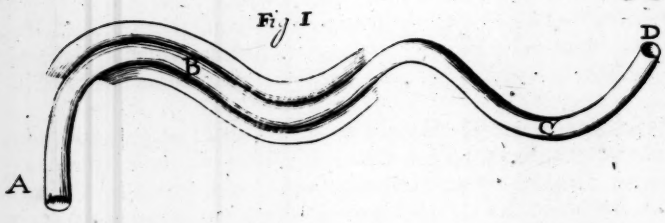

Fig. II.

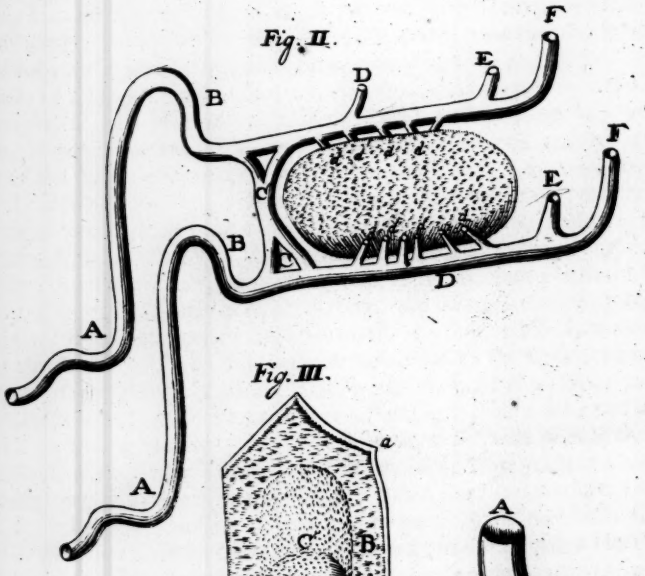

Fig. III.

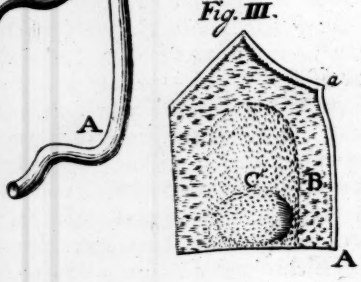

Fig. IIII.

preſently carried to the other, may find a paſſage: for this cauſe, to wit, that the blood might be the better prevented from any impediment in its paſſage, the Veſſels are not only inoculated under the *Dura Mater* about the wonderful Net, but the Arteries again on either ſide, do the ſame thing as ſoon as they being knit to the *Pia Mater*, reach the ſuperficies of the Brain, as hath been already ſhewn. By theſe ſort of ingraftings of the Veſſels in the wonderful Net, it comes to paſs, that an inky liquor being injected into one of the *Carotides*, and forced upwards, deſcends by the Trunk of the Artery on the oppoſite ſide, as we have elſewhere obſerved. Some rude draught of the wonderful Net is expreſſed in the third Figure of the following Table.

The Firſt Figure

Shews the aſcent of the Carotidick Artery, and its ſituation within an humane Skull, before it is carried towards the Brain.

A. *The Trunk of the Artery aſcending towards the Skull.*

BB. *The ſame, whilſt it is included in the bony Chanel, being clothed with an additional Coat.*

C. *The incurvature or bending of the Artery, reaching within the boſom of the Skull repreſenting the bending of a double S.*

D. *The Trunk of the ſame being carried towards the Brain.*

The Second Figure

Shews the aſcent of the Carotidick Arteries, and their ſituation in a Horſes Skull.

AA. *Either Carotidick Artery aſcending towards the Skull.*

BB. *The Trunk of either, having paſt the Skull, preſſed down as it were into a valley.*

CC. *The communications of either by croſs Branches.*

DD. *A Branch from either Trunk deſtinated for the* Dura Mater.

dddd. *Little ſhoots on either ſide ſent into the pituitary Glandula or* Kernel.

EE. FF. *Either Carotidick Artery being divided before it reaches the Brain, and aſcending with a double Trunk.*

The Third Figure

Shews the wonderful Net with the pituitary Kernel in a Calfs Skull.

A. a. *The direct Chanel of the Artery.*

B. *The Net-like Infoldings of the Veſſels ſtretched out by that Chanel towards the pituitary Kernel.*

C. *The pituitary Glandula or Kernel.*

The Fourth Figure

Shews after what manner the lateral Boſom goes into the Jugular Vein with a diverting place hanging to it.

A. *The lateral Boſom deſcending.*

B. *That Boſom ſliding into the Skull, and dilating it ſelf into a large and round Cavity, for the receiving of which there is a peculiar Den formed in the outward part of the Skull.*

C. *The aforeſaid Cavity or diverting place, in which the blood to deſcend, may go aſide, leſt it ſhould elſe ruſh too ſtrongly upon the Jugular Vein; by which alſo care is taken, that the blood may not flow back or regurgitate out of the Jugular Vein into to Boſom.*

D. *The beginning of the Jugular Vein.*

But as the *Carotides* (of whoſe office and aſcent we have hitherto ſpoken) carry the deſtinated Tribute of the blood to the Brain; ſo the Vertebrals ſerve chiefly for the watering the Cerebel and the hinder part of the oblong Marrow. Hence we obſerve, becauſe the conformation of the Cerebel is alike in Creatures, therefore alſo the Vertebral Arteries, different from the *Carotides*, are found alike in all without any great difference. Nor does there ſeem to be need of any great proviſion for the admiſſion or entrance of the Vertebral Arteries within the Skull; becauſe, as they carry a leſſer portion of the blood, and for that the Blood it ſelf that is beſtowed on the Cerebel, is wont there to be agitated or moved with no perturbations of paſſions or conceptions; therefore there is not that neceſſity that there ſhould be placed any remora or any incitement for its Torrent.

The Vertebral Artery, ariſing from the branch in the fifth Rib, in its whole aſcent through the hinder part of the Head, paſſes through the little holes cut in the extuberances of the *Vertebræ*, till it comes near the Baſis of the hinder part of the Head; where the ſame being bent down on either ſide, and admitted into the Skull by the laſt hole, excepting where the ſpinal Marrow goes forth, is carried by the ſide of the oblong marrow; but as ſoon as it is brought to the region or the Cerebel, it ſends forth branches on either ſide, which cover its ſuperficies, and beſides on its back ſide make infoldings no leſs ſignal than

thoſe commonly called the *Choroeides*, and with larger Kernels more thickly interwoven. As *theſe* ſhoots convey the Juyce requiſite for the ſtilling forth the animal Spirits, ſo *theſe* convey the heated blood and the purified from the ſerous Colluvies. Further, beneath the Cerebel, both the Vertebral branches, inclining mutually one to another, are united, as it were for that end, that if the flowing of the blood ſhould be ſtopped on either ſide, it might be ſupplied from the other to the whole compaſs of the Cerebel and its neighbouring parts. Theſe ſanguiferous Veſſels covering the Cerebel, even as the others do the Brain, make ſignal in foldings both in its outward ſuperficies, and in that of the oblong marrow, and alſo within its lappets and folds; from which ſmall ſhoots are ſent forth every where into its under-lying ſubſtance: ſo that from theſe a ſubtil liquor, as it were ſtilled forth and imbibed by the Cortical ſubſtance of the Cerebel, ſeems to go into animal Spirits. By what means, and in what parts of the Head the production of the animal Spirits is performed, remains next to be inquired into.

CHAP. IX.

Shews by what proviſion, and in what places of the Head the Animal Spirits are begotten: Alſo other Uſes and Accidents of the Pia Mater *are added.*

FRom the deſcription of the Sanguiducts or Blood-carrying Veſſels, which cover and weave about on every ſide the *Pia Mater*, hitherto handled, we are led by a certain thread to conſider by what proviſion, and in what places of the Brain and its Appendix the production of the animal Spirits is performed.

1. As to the firſt, it appears from what hath been already ſaid, that the blood is it ſelf the matter out of which the animal Spirits are drawn; and that the Veſſels containing and carrying it every where through the whole compaſs of the Head, are like diſtillatory Organs, which by circulating more exactly, and as it were ſubliming the blood, ſeparate its purer and more active particles from the reſt, and ſubtilize them, and at length inſinuate thoſe ſpiritualized into the Brain and its Appendix. Concerning this matter to be diſtilled, there is care taken, and indeed by the beſt means, that its ſtock or proviſion may be ſtill ſupplied in fit quality and due quantity.

In reſpect of the quality, from the whole bloody maſs, a portion highly volatile, ſpirituous, and endued with active Elements, ought conſtantly to ariſe towards the Head; which thing ſucceeds partly of its own accord, and partly that it might be more commodiouſly done, care is taken with a certain artificialneſs; to wit, the Vertebral Arteries, in all Creatures aſcending ſtraight, and almoſt perpendicularly, do in a manner cauſe, that only the more ſubtil and light blood is carried upwards, the remaining more thick as it were ſinking down for the baſer offices of the Limbs and of ſome of the Bowels. Yea, alſo the *Carotides* in a man, having an erected head higher than the reſt of the parts, and in a Horſe in ſome ſort lifting up his face, have alſo the ſame priviledge; to wit, that by their more ſteep aſcent only the more pure and volatile blood may aſcend to the region of the Brain. But in other four-footed beaſts, who go with a prone or hanging head, and who have a more frigid and watry blood, which may eaſily ſlide into, and too much waſh the Brain, this evil is in ſome part prevented by the wonderful Net and pituitary Glandula joyned to the *Carotides*; which indeed receive the ſuperfluous humidities of the blood, and and ſo make it more pure and free from dregs before it comes to the brain.

But that the blood may be ſupplied ſtill in due quantity, to wit, as it were in weight and meaſure, from the diſtillatory Veſſels, ſtretched about the compaſs of the Head, there is a notable proviſion made in all the *Carotides* about the Baſis of the Skull: becauſe their crooked imbowings and branching into infoldings, hinders the too great or too rapid approach of the blood: then, leſt the paſſage of it ſhould at any time be ſhut up, the mutual ingraſtings of all the Veſſels on either ſide, do help or provide for. After this manner, the buſineſs of extracting the animal Spirits is performed even as a Chymical Elixir; to wit, great care is taken in the beginning of that Operation, both that choice of matter may be had, and that only a due proportion of it be expoſed to the diſtillation.

The blood by this means, as it were a Chymical work prepared, is carried by the fourfold Chariot of the Arteries to four diſtinct regions of the Head: and as the ſanguiferous Veſſels, being diſtributed with ſeparate ramifications or branches through the whole compaſs of the Brain and its Appendix, cover all the heights of its compaſſings about or gyrations, and alſo its crevices and their gapings and receſſes, they bring to their doors the matter to be diſtilled into the Head every where through the whole circumference of the Brain and Cerebel nigh the Cortical ſubſtance of either; out of which as the Spirits are diſtilled, by this means it is brought about, that they are inſinuated into the ſubjected ſubſtance of either. The blood being carried through the narrow infoldings and divarications of the Veſſels as it were (as was ſaid) through the ſerpentine chanels of an Alembick is made extremely ſubtile, as much

as much as may be, in its liquor; in the mean time, what is bloody is received by the little ſhoots of the Veins aſſociates, or meeting one another every where, and what is ſerous by the Kernels every where diſperſed; yet its more purified and ſpirituous part being carried on further through the very ſmall ſhoots ſent forth on all ſides, are inſtilled more deeply into the very Pores and paſſages of the Brain and Cerebel; which preſently flowing from the Cortical ſubſtance into the medullary, there exerciſe the gifts of the animal Function. What peculiar body and conſtitutive particles of the Brain it ſelf and Cerebel, conduce to the generation and perfection of the animal Spirits within the ſubſtance of either, ſhall be ſhewn hereafter, when we treat of the Uſe of thoſe Parts: now ſhall be taken notice of what we before mentioned, to wit, that the fluid extillation of the ſpirituous liquor from the blood about the *Pia Mater*, is performed after a ſignal manner, both from the ambient heat, which is ſtirred up from the blood contained within the boſoms, as it were from a *Balneo Mariæ*, inriched by the continual flowing of it anew, and alſo from the obduction of the Meninges, like an Alembick, by which the ſpirituous Particles, apt to fly away, are conſtrained and forced into the parts beneath.

But indeed, though the animal Spirits are procreated wholly from the blood, yet the blood watering the Brain and its Appendix, is not only beſtowed on this work: for as to the ſanguiferous Veſſels, which ariſing out of the Trunks both of the Carotides and the Vertebrals, cover over the whole Head and all its parts and proceſſes; though many of them, yet not all, are little diſtillatory chanels of the animal Spirits. For the animal Spirits are not produced in all places, to which theſe Veſſels reach, for we affirm, that theſe Spirits are only procreated in the Brain and Cerebel: (which it were eaſie to prove by the Symptoms which happen in the Apoplexy and Palſie, and ſhall be afterwards clearly ſhewn) and from this double fountain of the animal Spirits they flow out into all the reſt of the parts, and Irradiate, by a conſtant influence, the whole nervous ſtock. In the mean time, the oblong marrow and its various proceſſes and protuberances are either retreating places, or high roads for the animal Spirits, procreated in the Brain and Cerebel, and flowing from thence. But for as much as the Arteries and Veins clothe theſe parts alſo with a thick ſeries of ſhoots, and that within the infolding of the Brain the folds called *Choroeides* are hung ſlack and looſly, theſe ſeen to be ſo made for other reaſons, *viz.* both that theſe parts might be actuated by heat, ſupplied as it were from a continual fire, and alſo that the nouriſhing Juyce might be beſtowed on the Spirits which flow there.

As to the firſt, that the animal Spirits now perfected, may be freely expanded, and irradiate the nervous *Syſtem*, there ſeems to be required, that the ambient heat, being excited by the blood flowing thither, might open all the little ſpaces for their paſſage, and notably dilate or lay open for them ways or roads: wherefore we intimated before, becauſe the little ſhoots of the Veſſels ought not to be deeply inſerted into callous body, (for that, leſt the commerce of the Spirits, diverting in this Mart or meeting place, ſhould be diſturbed by the perpetual influence of the blood) therefore the infolding of the *Choroeides* is hung under its chamber, that at leaſt by this nigh ſituation, as by a Stove or Hot-Houſe, the heat there might be preſerved. Beſides, we intimated another uſe of this infolding; to wit, that the blood, paſſing through the very narrow *Meanders* and convolutions or rollings about of the Veſſels, might lay aſide its ſerous recrements into the Glandula's or paſſages of the Veins.

2. But ſecondly, That many branches and leſſer ſhoots of the ſame Veſſels, which water the Brain and Cerebel, cover alſo the oblong marrow, and in ſome meaſure enter into its Pores and deeper ſubſtance (within which the animal Spirits are not begotten, but only exerciſed and expanded) I ſay, that this is ſo made for this other reſpect; to wit, that the ſubſtance of the oblong marrow might imbibe a conſtant proviſion of nouriſhment from the pouring in of the blood whereof it hath need. For whilſt the animal Spirits, flowing into the nervous ſtock from the Brain and Cerebel, paſs through this paſſage, as it were the high road, ſome food here ought to be adminiſtred to them, as it were in their journey, from the watering blood: For indeed we ſuppoſe (which alſo will afterwards clearly appear) that the oblong marrow, together with the nervous parts, is moiſtned with a double humor, *viz.* one ſpirituous and highly active, which flows altogether from the Brain and Cerebel, and being from thence derived into the whole nervous ſtock, beſtows upon them the ſenſitive and moving Faculties; and the other humor ſofter and more oily and ſulphureous, which being ſupplied from the blood, and affuſed immediately on every part, is the Author of their Heat and Vegetation. Both theſe Juyces agree among themſelves, and being every where joyned together and married, they are as it were a maſculine and feminine ſeed mixed together; and ſo they impart to all parts both ſenſe and motion, and all the powers of life and growth. Wherefore it is obſerved, that all the parts of the whole body, by which motion and ſenſe are performed, do not only ſwell up with the animal Spirit, of whoſe influence being deprived, they preſently ſuffer a reſolution or looſning; but alſo they admit the ſanguiferous Veſſels, of whoſe Tribute if they be defrauded, preſently they wither away, or are diſtempered with a mortification or Gangrene. Wherefore, that the fleſh, membranes, and all the bones may be watered with the blood, (as may be perceived by the help of a Microſcope) the very little or minute bodies of ſome of the Nerves are ſurrounded with Capillaments or little hairs of Arteries and Veins, together with their proper Fibrils, that we need not doubt to aſſert, that the Veſſels penetrating the ſuperficies of the *Brain* and *Cerebel*, do diſtil into them a ſubtil matter for the generation of the animal Spirits; but that ſome other ſhoots of the ſame Veſſels, covering the oblong marrow, do only impart to it heat and nouriſhing Juyce. Laſtly, that the infoldings of the *Choroeides* were built under the chamber of the oblong marrow, chiefly for the diſpenſing of heat,

and in ſome meaſure for the ſake of ſeparation of the ſerous *Latex*. But concerning theſe, we ſhall have occaſion to ſpeak more largely afterwards, when we ſhall treat of the nutritious and nervous Juyce, and when we ſhall conſider of that famous Controverſie, *viz.* whether nouriſhment is made by the blood or Nerves: further, we ſhall elſewere ſpeak more fully of the Nature, Hypoſtaſis, and diverſe Diſpoſition of the animal Spirits; alſo, what the ſubſtance of the Brain, and the conformation of the parts, may contribute to their production.

Thus far concerning the *Pia Mater* and the blood-carrying Veſſels, which are woven in it, and following its protenſion, water the whole Head, we have treated largely. But before we quite leave the conſideration of this Membrane, we will inquire what ſenſe and motion it may have. Certainly it is not undeſervedly that we aſcribe the moſt cruel Head-aches to the more acute ſenſe of this; (in which however, by what means this Meninx is affected, does not ſo eaſily appear.) It is the common opinion, that ſharp and tormenting Vapours, being raiſed from the Viſcera of the lower Belly, eſpecially from the Ventricle, Hypochondria, or Womb ſtrike againſt this Membrane, and ſo pierce it with a pain. But we ſay, though this be impoſſible, that Vapours paſſing ſo many interſtices and bars of the Viſcera and bones, without any trouble, ſhould ever come to the Head and hurt it; yet we do not deny, but that ſometimes vaporous Effluvia's do proceed from the blood boiling or eſtuating within the confines of the Brain, which being ſhut up together under the *Pia Mater*, and as it were gathered into a Cloud, do greatly blow up and diſtend it, and ſo diſtemper it with pain. I have often ſeen, in a Head newly opened after death, the *Pia Mater* diſtended, and ſhining like a Bladder, that the ſame ſeemed to be intumified, with much water included under it; which notwithſtanding was found to be ſo done by wind diſtending the Membrane, for that being diſſected, that Tumor fell down without the effuſion of water.

But we think the Head-aches, which happen by reaſon of the evil of this Membrane, are chiefly excited by another means, to wit, for as much as this Meninx ſuffers a breach of the unity by the blood boiling up above meaſure, and ruſhing into its Pores, and ſo it is contracted into lighter Convulſions. I have ſometimes opened the Heads of the defunct, which when living, were obnoxious to moſt miſerable Head-aches; in which, near the longitudinal boſom, where the ſeat of pains was, the *Pia Mater* or interior, grew to the *Dura Mater* or exterior for ſome ſpace, oft-times for two fingers breadth, and by their growing together had excited a ſharp and unequal Tumor; in which the mouths of the Veſſels were ſo wholly ſtopped up, that there was left for the blood, though very much boiling up, no paſſage into the adjoyning boſom.

As to the motion of this Membrane, we wholly deny, that it hath in it ſelf a perpetual Syſtole and Diaſtole; however, the Pulſes in ſome Arteries, have ſeemed ſomething like it, which have given occaſion perchance to this vulgar Opinion. Yet in the mean time, it may be lawful to believe, that this Meninx, for that it is very ſenſible, is rendred obnoxious to Cramps and convulſive motions: and from its greater contraction the fits of the Falling-ſickneſs do ariſe, and from its leſſer and more partial corrugation or wrinkling together, Head-aches, as hath been ſaid, and alſo ſometimes Scotomies, Vertigoes, and often Convulſions of the Members and Viſcera, planted at a great diſtance from the origine of the Nerves, being drawn into conſent.

CHAP. X.

A Deſcription of the Brain, properly ſo called, and the Explication and Uſe of its Parts.

WE have thus far beheld the Coverings of the Brain, both the bony and the membranous, alſo the Arteries and Veins growing and knit to them, like Ivy, and diſtributed through the whole compaſs of the Head. There now remains, theſe coverings being removed, that we next conſider the Fabrick and true Hypotype or Character of the Brain and its Appendix, together with the action and uſe of all the parts. And here at firſt ſight we meet with three things, to wit, the Brain, the oblong Marrow, and Cerebel: of which the oblong marrow ſeems to be a common Trunk, to which the Brain and Cerebel grow like branches: wherefore ſome contend the medullary Rope to be the principal part, and the Brain and Cerebel its dependences. But that it is otherwiſe appears by this, becauſe theſe bodies, both in the generation and diſpenſation of the animal Spirits, are of more noble uſe than the oblong marrow; ſo that if the out-flowings of the Spirits from the Brain or Cerebel be ſhut up or hindred, the nervous Syſtem preſently ſuffers an Eclipſe; in the mean time, if this be primarily diſtempered, the Brain and Cerebel ſuffer not for its fault.

That

That we may begin with the Brain, it may be conſidered in a double reſpect; to wit, both as to its convex or exterior ſuperficies, as it is beheld in its proper ſite and poſition; and as to its interior cavity, to wit, as the Brain appears opened, its concave ſuperficies being expanded and turned upſide down. We have already taken care to delineate its true form or Type in either manner, by what hath been before ſaid, to wit, after what manner it is both within and without. There now remains, after its fabrick and conformation being rightly weighed, for us to deſign its offices, and to ſhew the uſes of it and of every one of its parts. Concerning which, we ought to unfold in general, firſt, what the office of the whole Brain is; then ſecondly, when we ſhall deſcend to particulars, there will come under conſideration, 1. The diviſion of the Brain, to wit, its double Hemiſphere, alſo the two Lobes or partitions of either. 2. The narrow crankling turnings and windings, or the gyrations and convolutions or rolling together of the Brain. 3. Its double ſubſtance, *viz.* Cortical and Medullary. 4. The common Baſis of all, *viz.* the callous body. 5. Its ſubtenſion or *Fornix*. 6. The appenſion or circuit of the Brain over or above the oblong marrow. 7. And what reſults from thence, the void ſpace or Ventricles made by its infolding together. Concerning theſe, we ſhall take notice of what things occur worth noting; concerning the ſmelling Nerves and their proceſſes, we ſhall inquire afterwards, when we ſhall ſpeak particularly of the Nerves.

1. The Brain is accounted the chief ſeat of the Rational Soul in a man, and of the ſenſitive in brute beaſts, and indeed as the chief mover in the animal Machine, it is the origine and fountain of all motions and conceptions. But ſome Functions do chiefly and more immediately belong to the ſubſtance of this, and others depend as it were mediately and leſs neceſſarily upon it. Among theſe, which of the former ſort are accounted the chief, are the Imagination, Memory, and Appetite. For it ſeems, that the Imagination is a certain undulation or wavering of the animal Spirits, begun more inwardly in the middle of the Brain, and expanded or ſtretched out from thence on every ſide towards its circumference: on the contrary, the act of the Memory conſiſts in the regurgitation or flowing back of the Spirits from the exterior compaſs of the Brain towards its middle. The Appetite is ſtirred up, for that the animal Spirits, being ſome-how moved about the middle of the Brain, tend from thence outwardly towards the nervous Syſtem. The reſt of the Faculties of this Soul, as Senſe and Motion, alſo the Paſſions and Inſtincts merely natural, though they depend in ſome meaſure upon the Brain, yet they are properly performed in the oblong Marrow and Cerebel, or proceed from them.

2. In ſome Animals, the ſubſtance of the Brain is divided into two parts, as it were Hemiſpheres, diſtinct one from another almoſt through its whole thickneſs, even to the callous body, which is inſtead of a bottom; and in like manner alſo in all the Senſories, and in moſt of the other Organs of the neceſſary Functions, the Brain is as it were twofold, that there might be a proviſion made againſt the defect of one ſide by the ſupplement of the other. Further, in man, who hath a brain more large and capacious than other Creatures, either Hemiſphere is again ſubdivided into two Lobes, to wit, the Anterior and the Poſterior; between which a branch of the Corotidick Artery, being drawn like a bounding River to both, diſtinguiſhes them as it were into two Provinces. Certainly, this ſecond partition of the humane Brain alſo ſeems to be deſigned for its greater ſafety; that if perchance any evil ſhould happen to one or both the foremoſt Lobes, yet the latter, for that they are ſeparated, may avoid the contagion of the neighbouring and farther ſpreading evil: So the Brain, like a Caſtle, divided into many Towers or places of Defence, is thereby made the ſtronger and harder to be taken.

3. Alſo the univerſal frame of the Brain appears yet more divided and variegated within all its aforeſaid partitions; for all its whole exterior ſuperfices is made uneven and broken, with turnings and windings and rollings about, almoſt like thoſe of the Inteſtines. Thoſe Gyrations or Turnings going from the fore-part of the Brain towards the latter with a creeping compaſs, and as it were a ſpiral circuit, encompaſſes both its Hemiſpheres, that they mighty mutually furniſh all the convolutions with a continued paſſage: in a more moiſt Brain, or long kept, the *Pia Mater*, clothing every one, and collecting them together, is eaſily pulled away; and then the turnings or folds being opened and ſeparated one from another, the ſubſtance of the brain is ſeen to be plowed, or laid as it were with furrows; out of which ariſe banks or ridges of broken crevices, not in a direct ſeries, but croſs-wiſe; ſo that the bottom of every furrow, a convultion ariſing from the right ſide, is carried to the left; then others following next, being ſent from the left ſide, is drawn to the right, and ſo by turns the inequalities of the whole brain are variegated in this order.

If it be inquired into, what benefit its Turnings and Convolutions afford to the brain, or for what end its whole anfractuous or broken crankling frame is, we ſay that the brain is ſo framed, both for the more plentiful reception of the ſpirituous aliment, and alſo for the more commodious diſpenſation of the animal Spirits for ſome uſes. As to the aliment to be beſtowed on the brain, becauſe it is required to be ſubtil and extremely wrought or elaborated; therefore it ought to be admitted, not by a more open paſſage, but only by very ſmall pores and paſſages. Wherefore that there might be ſufficient plenty of ſpirituous liquor ſupplied, it is not only drunk in every where in the plain ſuperficies of the brain from its Cortical ſubſtance; but that ſuperficies of the brain or Cortical ſubſtance is uneven and rough with folds and turnings about; that the ſpaces for the receiving the Juyce might be enlarged as much as may be: For the anfractuous or crankling brain, like a plot of ground, planted every where with nooks and corners, and dauks and mole hills, hath a far more ample extenſion, than if its ſuperficies were plain and even

Further

Further, thoſe cranklings of the brain do more fitly hide the ſanguiferous Veſſels, for that they are very ſmall and ſlender, and more ſafely keep them, being variouſly interwoven into one anothers infoldings, than if they ſhould be openly diſtributed; for ſo being careleſly laid, they would be liable to too frequent hurt.

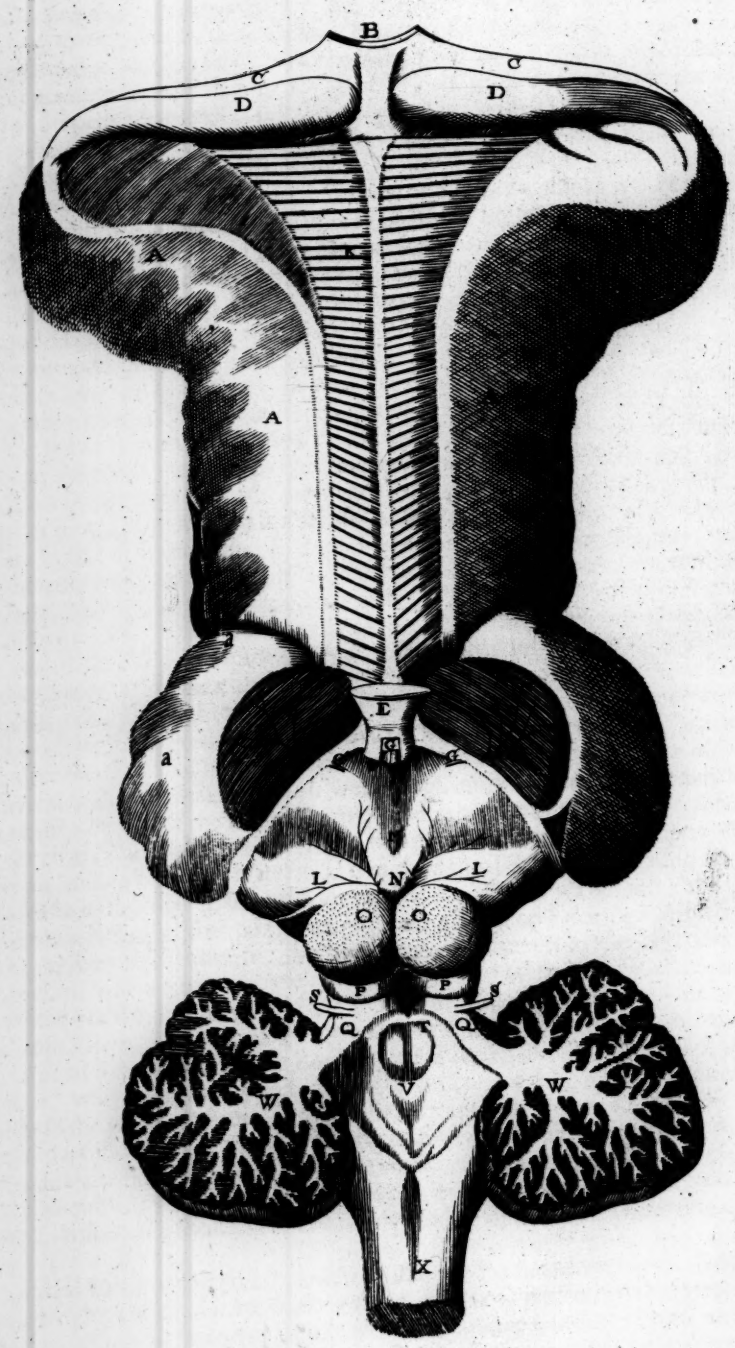
But a reaſon and neceſſity of the turnings about the brain, and not of leſſer moment than the other, is fetched from the diſpenſation of the animal Spirits. For as the animal Spirits, for the various acts of Imagination and Memory, ought to be moved within certain and diſtinct limited or bounded places, and thoſe motions to be often iterated or repeated through the ſame tracts or paths: for that reaſon, theſe manifold convolutions and infoldings of the brain are required for theſe divers manners of ordinations of the animal Spirits, to wit, that in theſe Cells or Store-houſes ſeverally placed, might be kept the ſpecies of ſenſible things, and as occaſion ſerves, may be taken from thence. Hence theſe folds or rollings about are far more and greater in a man than in any other living Creature, to wit, for the various and manifold actings of the ſuperior Faculties; but they are garniſhed with an uncertain, and as it were fortuitous ſeries, that the exerciſes of the animal Function might be free and changeable, and not determined to one. Thoſe Gyrations or Turnings about in four footed beaſts are fewer, and in ſome, as in a Cat, they are found to be in a certain figure and order: wherefore this Brute thinks on, or remembers ſcarce any thing but what the inſtincts and needs of Nature ſuggeſt. In the leſſer four-footed beaſts, alſo in Fowls and Fiſhes, the ſuperficies of the brain being plain and even, wants all cranklings and turnings about: wherefore theſe ſort of Animals comprehend or learn by imitation fewer things, and thoſe almoſt only of one kind; for that in ſuch, diſtinct Cells, and parted one from another, are wanting, in which the divers Species and Ideas of things are kept apart.

But that in more perfect Animals, all the turnings about are made of a twofold ſubſtance, *viz.* Cortical and Medullary: the reaſon ſeems to be, that one part may ſerve for the production of the animal Spirits, and the other for their exerciſe and diſpenſation. For we may well think, that the animal Spirits are wholly or for the moſt part procreated in the Cortical ſubſtance of the brain; for this ſevers and receives immediately from the blood the ſubtil liquor, and imbuing it with a volatile Salt, exalts it into very pure Spirits. It is obvious to every one, that the Arteries enter the *Cortex* of the brain with a more frequent inſertion of ſhoots, and inſtil to it a ſpirituous liquor; the leavings of which, or what is ſuperfluous, the Veins in like manner entring it, do ſup up and carry away; in the mean time, the more ſubtil portion being here ſet free, goes into Spirits. In truth, the blood waters the medullary ſubſtance of the brain in a very ſmall quantity; which ſeems truly to be rather for the ſake of exciting of heat, than that the animal Spirits ſhould there be generated by the flowing in of that blood. For indeed, the volatile Salt, which like Ferment, ſpiritualizes the ſubtil liquor ſtilled forth from the blood, is had more copoiuſly in the *Cortex* of the brain, rather than in its mdidle or marrowy part; becauſe that part being endued with an Aſhy colour, ſhews by its aſpect the ſpermatick Particles and Humor contained in them, in which Spirit and a volatile Salt very much abounds; yea and plainly reſembles on Armeniack ſmell, (ſuch as either part alike breathe forth.) In the mean time, the medullary part of the brain ſeems very like the oblong marrow and the ſpinal. But it is well enough known, that theſe medullary parts ſerve for the exerciſe and diſpenſation of the animal Spirits, and not for their generation. The ſign of which is, that where-ever an obſtruction happens in them, whatever is below, being deſtitute of the influx of the Spirits, ſuffers an Eclipſe; whence it follows, that the animal Spirits, irradiating the medullary Rope, are not produced in it, but flow in from elſewhere; and why ſhould we not think the ſame of the middle marrow of the brain? Truly, that this part is rather the Mart or Exchange of the Spirits than its Shop or Work-houſe, appears from hence, becauſe the Animals which excel in Memory, Imagination, and Appetite, are furniſhed with a more ample marrow of the brain; as is obſerved in man and the more perfect four footed beaſts: and they who ſeem to have little need of thoſe Faculties, as the leſſer four-footed beaſts, alſo Fowls and Fiſhes have the *Cortex* of the brain greater, but the medullary part very ſmall. It is a familiar Experiment among Boys to thruſt a needle through the head of a Hen, and that ſhe in the mean time, whoſe brain is ſo pierced through, ſhall live and be well a long time. The reaſon of which is, becauſe the whole ſubſtance of the brain in theſe ſort of Animals is almoſt merely Cortical; wherefore from the ſuffering ſuch a hurt, (as long as the marrow remains unhurt) the Spirits are generated in a leſſer quantity, but their commerce to the neceſſaries of life, are not therefore preſently interrupted. Indeed the brains of Birds conſiſt almoſt wholly of a Cortical and Aſhy part; and the medullary part is exceeding ſmall, and is only like a ſmaller Nerve deſcending on either ſide from the ſubſtance of the brain it ſelf.

After the animal Spirits are begot by a conſtant afflux of the blood within the *Cortex* of the Brain, being there begotten, having obtained a watry Vehicle, they flow preſently more inwardly, and ſoon enter into the marrows, filling the furrows and baulks of all the turning and winding Crevices; from whence being carried farther through all the particular tracts of each marrow into the marrowy ſubſtance, which lyes under all the winding Crevices, as their common Baſis, they are brought at laſt into the *Callous Body*, as into a ſpacious field; where, as in a free and open place, theſe Spirits being newly produced, are expatiated or iſſue forth.

5. Indeed

Fig. VII.



5. Indeed this medullary ſubſtance called the *Callous Body*, which chambering the more inward ſuperficies of the brain, receives into it ſelf the marrow of all the turning Crevices, ſeems to be made for that end, and diſpoſed there for the ſame purpoſe; to wit, that the Spirits flowing into it on every ſide, might be ſtretched out as in their proper Sphere, and begin to exerciſe the acts of the animal Faculties. In this place, they which come out of the ſeveral winding Crevices, do meet together, and remain as in a publick *Emporium* or Mart; from whence, as occaſion ſerves, they are raiſed up, and drawn forth for the uſes of every Faculty. But whilſt they here remain at leiſure and not buſied, they become purified or refined more and more by a continual circulation: becauſe theſe Spirits new-born, do gently and perpetually flow on every ſide from the outmoſt bounds of this body (to wit, where this common marrow beſmears the hinder productions of the brain, or the border of either of its Hemiſpheres) towards the forepart of this *callous Body*, where it is thickeſt; and there, if there be need, they are employed on the act of the Imagination, or entring the ſhanks of the *oblong Marrow*, they actuate and inſpire the nervous *Appendix*: but what Spirits are remaining there, after theſe offices are ſerved, run forthwith into the *Fornix*, and paſſing through its paſſage, they are remanded back again to the hinder region of the brain by a certain circulation; and laſtly, after this manner, penetrating through the narrow paſſages of the *Fornix*, thoſe Spirits are made more ſubtil, and alſo, as it ſeems moſt likely, they perfom in this circulary motion thoſe more ſubtil acts of the Phantaſie.

6. Truly, that we may here ſpeak ſomething of the *Fornix*, it ſeems that this part ſerves for a towfold uſe: *viz.* firſt, leſt more inward ſides of the Brain hanging ſlack and looſly, might fall together among themſelves, or might be removed beyond the limits of a juſt protenſion or out-ſtretching; for they not only by the coming between of the *Pia Mater*, and by little cords drawn from it, cohere to the oblong marrow and the Cerebel; but beſides, the *Fornix*, like a Ligament or ſtring brought from one end of the brain to the other, conſtrains and keeps its whole frame in its due figure and ſituation. For this part purely medullar, and of the ſame ſubſtance with the callous Body, ſeems to be a certain proceſs of this, which ariſing more forward between the ſtreaked bodies, and falling upon the two ſhanks of the oblong marrow, firſt of all diſtinguiſhes them: afterwards, being ſeparated from them, is carried through the midſt of the cavity, and about the hinder part of the brain is divided as it were into two Arms, which being bent on both ſides, and again cleaving to the border of the *callous Body*, ſtrictly embrace the oblong marrow, and knit and firmly tye the hinder bulk of the brain to its Trunk, leſt it ſhould flow or ſlide forth. But the other, and that the more noted uſe of the *Fornix* ſeems to be what we but now mentioned; to wit, that the animal Spirits may immediately paſs through its paſſage from one end of the brain to the other, and ſo, as it were through the bill of a *Pelican*, they might be circulated into their own intorted belly.

That thoſe things were but now declared concerning the *Penetralia* and inward receſſes of the Brain, may be the better underſtood, we will here add a Scheme of its Sphere turned inſide out, and ſtretched out as it were upon a plain, ſo that the concave and inmoſt ſuperficies of the *callous Body*, together with the *Fornix*, may be ſufficiently ſeen.

The Seventh Figure

SHews the Brain of a Sheep bent back and cut a little open in the places where they ſtick together near the ſtreaked bodies, that its interior ſubſtance may be turned the inſide out, and unfolded on a plain.

AA. *The ſubſtance of the Brain cut aſunder, which in its natural ſituation being folded together, did cohere with the reſt of its ſubſtance* a. a. *upon the remaining ſtreaked Bodies.*

B. *The Trunk of the* Fornix *or* Pſalloides *cut aſunder, which in its natural ſite coheres with the Baſis of the ſame* Fornix E.

CC. *The Arms of the* Fornix *which embrace the medullary Trunk on the other ſide of the Pineal Glandula.*

DD. *The brim of the callous Body which embraces the medullary Trunk near the Cerebel.*

E. *The Baſis of the* Fornix.

FF. *Two ſtraight Roots of the* Fornix *lying between the ſtreaked Bodies.*

GG. *The tranſverſe medullary Proceſs knitting the two ſtreaked Bodies one to another.*

H. *The Chink near the Roots of the* Fornix *leading to the Tunnel.*

I. *The ſtreaked Bodies, whoſe Superficies the ſmall Arteries and Veins cover over.*

KK. *The interior Superficies of the callous Body marked with tranſverſe medullary ſtreaks or chanſferatiugs, or reaching from one Hemiſphere of the Brain to the other.*

LL. *The Chambers or hollow places of the Optick Nerves.*

M. *The anterior hole leading to the Ventricle lying under the orbicular Protuberances, which alſo goes ſlope-wiſe to the Tunnel.*

N. *The Pineal Glandula which appears more plain, the* Pia Mater *and the Choroidal infolding being ſeparated and removed.*

OO. *The Natiform or Buttock like Protuberances, which are here far greater than in a Man or Dog.*

PP. *The leſſer Protuberances called* Teſtes, *which are additions or things growing out of the former.*

QQ. *The*

QQ. *The medullary Proceſſes ſtretching from the* Teſtes *into the middle or marrowy part of the Cerebel.*
R. *The meeting together of thoſe Proceſſes.*
SS. *The Pathetick Nerves of the* Eyes *ariſing out of the meeting together of thoſe Proceſſes.*
T. *The poſterior hole leading into the Ventricle, lying under the orbicular Protuberances, and alſo into the ſame opening of the Tunnel.*
V. *A Furrow in the medullary Trunk, which being covered by the Cerebel, makes the fourth Ventricle.*
WW. *The Ramifications or Branchings of the medullary ſubſtance of the Cerebel, which appear like a Tree.*
X. *The end of the oblong Marrow about to go into the Spinal.*

CHAP. XI.

Shews with what motion and tendency of the Animal Spirits, the Exerciſes of the Animal Faculties are performed within the Confines of the Brain: Alſo what the uſe of its Ventricles is.

HItherto ſetting forth the uſes and offices of the Brain, properly ſo called, and of its parts, we have ſhewed after what manner the animal Spirits are procreated from the blood in this their principal Shop or Work-houſe; and into what diverting places, they being newly brought forth, do depart of themſelves, and are there kept as it were in diſtinct Cloiſters or Cells to be drawn forth for the manifold Exerciſes of the animal Function. But becauſe theſe Spirits, ſo brought to perfection, and ready for their work within the ſame parts of the Brain, enter into other manner of motions, and divers ways of emanations; therefore before we proceed any further, for the ſearching out their tracts within the oblong Marrow and Cerebel, we ought to declare concerning theſe Spirits diſpoſed within the confines of the Brain it ſelf, with what forces they are furniſhed, in what form they unfold themſelves, and in what ways they diffuſe themſelves and go forward as often as being muſtered in due order, they produce the acts of the Imagination, Memory, Appetite, and other ſuperior Faculties of the Soul. But for as much as hereafter, when we have finiſhed the explication of the Head and nervous Appendix, we have reſolved, for a concluſion, to treat of the Soul of Brutes and its powers, I may therefore for the preſent lay aſide this task; unleſs that in the mean time it may not ſeem amiſs to give a taſte only in general of theſe few things: *viz.* as there are two parts of the inferior Soul, or of Beaſts, to wit, the vital or flamy, being inkindled in the blood, and the ſenſitive or lucid, being diffuſed through the whole Head and its nervous dependences, the animal Spirits being continually produced in the Brain and in the Cerebel, do conſtitute a double as it were Root or Fountain of this lucid part: yea, the Spirits of either linage, for as much as they are continued both within thoſe Fountains, and from thence through the frame or ſubſtance of the nervous Syſtem, as it were under the ſame beamy *Syſtaſis* and contexture, they effect or cauſe the whole *Hypoſtaſis* or ſubſiſtency of the ſenſitive Soul.

But there happen to this Soul, becauſe it is apt to be moved with a various impulſe, and ſo to contract or dilate its ſpecies in the whole, or in part, for that reaſon divers manners both of Actions and of Paſſions, to wit, the Senſes, which we call its Paſſions; and Motions, which we name the Actions of the ſame. The formal reaſon of the former, *viz.* the Senſes, conſiſts in the retraction or drawing back of the Spirits, or a flowing back towards their Fountains. For where-ever the impreſſion of a ſenſible object is carried to this radiant or beamy contexture, preſently either the whole frame, or ſome portion of it, whereby it admits the ſpecies, is compelled to wag, and to be moved back, as it were to leap back and recede into it ſelf: on the contrary, the actions or motions of this Soul are made, for that this ſhadowy Spirit, being incited or ſtirred up in the whole, or in a certain part, unfolds it ſelf more largely, and by an emanation, and as it were a certain vibration of the Spirits, exerts or puts forth its virtue and force of acting.

Both the Senſes and Motions of this ſenſitive Soul are made either tranſient, when the Spirits, or its conſtitutive Particles, being moved ſomewhere in the Syſtem of the Nerves, draw together with them the containing parts, and deflect them with the like carriage or geſture with themſelves, as is obſerved in the five outward Senſes, and the local motions of the Members: or elſe, either both Actions and Paſſions are continuing, to wit, when both the Motions and Senſes are ſilently performed without any great agitation or moving of the body, or its parts, within the firſt Fountains of the Soul, *viz.* the Head it ſelf. Theſe kind of Paſſions indeed, made within the ſubſtance of the Brain, are the common Senſe and Imagination; but the Actions are Memory, Phantaſie, and Appetite: and either of theſe, as to their beginnings and inſtincts, depend for the moſt part upon the outward Senſes.

Concerning

Concerning the former, we take notice, that as often as the exterior part of the Soul being ſtruck, a ſenſible impreſſion, as it were the Optick Species, or as an undulation or waving of waters, is carried more inward, bending towards the chamfered bodies, a perception or inward ſenſe of the Senſation outwardly had or received, ariſes. If that this impreſſion, being carried farther, paſſes through the *callous Body*, Imagination follows the Senſe: Then if the ſame fluctuation of Spirits is ſtruck againſt the *Cortex* of the Brain, as its utmoſt banks, it impreſſes on it the image or character of the ſenſible Object, which, when it is afterwards reflected or bent back, raiſes up the memory of the ſame thing.

The active Powers of this Soul, *viz.* Local Motion, Memory, Phantaſie, and Appetite follow ſometimes immediately the Paſſions, ſometimes are induced apart from them upon other occaſions. For indeed the ſenſible impreſſion ſtriking the ſtreaked or chamfered bodies, oftentimes, the Brain being in no wiſe affected, cauſes the local Motions to be retorted with a reciprocal tendency of the animal Spirits; ſo in ſleep (the Appetite knowing nothing of it) when pain troubles, preſently we rub the place, moving the hand to it: but more often, after that the ſenſible Species, having paſt from the common Senſory to the *callous body*, hath ſtirred up the Imagination, the Spirits, reflecting from thence, and flowing back towards the nervous Appendix, raiſe up the Appetite and Local Motions, the Executors or Performers of the ſame: And ſometimes a certain ſenſible impreſſion, being carried beyond the *callous Body*, and ſtriking againſt the *Cortex* of the Brain it ſelf, raiſes up other Species lying hid there, and ſo induces Memory with Phantaſie, alſo often with Appetite and Local Motion aſſociates. Further, theſe active Powers, ſometimes upon other occaſions, are wont to be ſtirred up and exerciſed apart from Paſſion. In Man, the Rational Soul variouſly moves the ſenſitive, and at its pleaſure draws forth and brings into act its Powers, ſometimes theſe, ſometimes thoſe. Moreover, the blood boiling up above meaſure, and by that means ſtriking impetuouſly the border of the Brain, excites the ſpecies of things lurking in it, and driving them forward towards the middle or marrowy part of the Brain, cauſes alſo the various Acts of the Phantaſie and Memory to be repreſented.

Concerning the aforeſaid interior or abiding Faculties, we ſhall at preſent further take notice, that their more perfect Exerciſes are chiefly and almoſt only performed by the Spirits already perfected and highly elaborated; for thoſe a making, or that are new made, being numerous, they very much obſtruct and hinder the acts of the animal Function: to wit, when from the Veſſels, on every ſide watering the *Cortex* of the Brain, the ſubtil Liquor is plentifully inſtilled for the matter of the Animal Spirits, this flowing inwardly ſtuffs all the pores and paſſages of the Brain, and ſo excludes for that time the Spirits from their wonted tracts and orbs of expanſion. Wherefore whilſt the chief reflection of the Brain and Spirits is celebrated, ſleep, or an Eclipſe of the animal Spirits happens; then waking returns, when from the Liquor inſtilleds the more ſubtil part is exalted into very pure Spirits, and at length the more watry, being partly reſolved into Vapours, is exhaled, and partly ſupped up by the paſſages of the Veins entring the ſubſtance of the Brain, or elſe is ſweat out into the vacuity lying under the *callous Body*. Concerning theſe I hope we may diſcourſe more largely afterwards. In the mean time, that we may proceed to the reſt of the things propoſed, concerning the frame of the Brain, properly ſo called, there yet remains that we ſpeak of its Ventricles: But ſince they are only a vacuity reſulting from the folding up of its exterior border, I ſee no reaſon we have to diſcourſe much of their office, no more than Aſtronomers are wont of the empty ſpace contained within the vacuity of the Sphere.

But in truth, as there is nothing met with in Nature that is not deſtinated to ſome uſe, ſurely we ſuſpect this ſame *Vacuum* or empty ſpace not to be built in vain within the Globe of the Brain. The Ancients have ſo magnified this Cavern, that they affirmed it the Shop of the Animal Spirits, both where they themſelves were procreated, and performed the chief works of the animal Functiou. But on the other ſide, the Moderns or thoſe of later days have eſteemed theſe places ſo vile, that they have affirmed the ſame to be mere ſinks for the carrying out the excrementitious matter. But indeed that opinion of the Ancients is eaſily overthrown, for that the animal Spirits, being very ſubtil, and apt to fly away, require not ſuch large and open ſpaces, rather than the more narrow paſſages and little pores, ſuch as are made in the ſubſtance of the Brain: for theſe Spirits (becauſe they ought, for the various Faculties of the Soul, to be compoſed into various ſeries, and divers orders and diſpoſitions, therefore) ought to be moved within peculiar orbs and tracts. Further, if any one ſhall exactly conſider the fabrick of the Brain, and ſeriouſly weigh, that theſe Ventricles are not formed out of the primary intention of Nature, but reſult only ſecondarily and accidentally from the complication of the Brain, he will be far from thinking, that the ſupreme ſeat of the Soul is fixed there, where being hem'd in with a moſt noble Guard of Spirits, it doth execute and perform its Functions. For it neither appears at all out of what matter, and by what artifice the Spirits are there begotten, nor by what ways of emanation they are derived from thence into the other parts of the Brain and nervous Syſtem. Wherefore almoſt all Anatomiſts, who are of a later Age, have attributed that vile office of a Jakes or ſink to this more inward chamber of the Brain. To which Opinion there has been ſome truſt given, for that theſe Ventricles are often ſeen in the dead to be filled with water; alſo from theſe, ways ſeem to lye open for excretion, both towards the Tunnel, and alſo into the Sieve-like Bone. It is obſerved, that where-ever the blood flows more copiouſly into any part, and waters it, there Vapors or watry Humors are begotten from the ſuperfluous Serum left in the circulation, which for the moſt part either exhale out through vaporous *Effluvia's*, or are brought back into the blood by the Veins or Lymphatick Veſſels. But when the blood, by a plentiful influx, waters not only the *Cortex* of the Brain, but

the interior marrow alſo, it remains, that the ſerous *Latex* (when-ever it abounds more in the blood, than that its ſuperfluities may be reduced immediately by the Veins, or by the Lymphæducts, if they be there, or may be ſeparated by the Glandula's) ſhould ſlide down into this den, made hollow within the infolding of the Brain. Truly there are many inſtances, which plainly evince, that the ſerous humors are ordinarily laid up in the Ventricles of the Brain. Anatomical Obſervations of men dying of many Cephalick diſeaſes, and eſpecially of ſoporiferous or ſleepy diſtempers, confirm this. Yea, it may be lawfully thought, that natural ſleep follows, for that the Pores and paſſages of the Brain are occupied and ſtuffed with a watry *Latex*, which ſerves for a Vehicle to the Spirits. Then as often as a profound ſleep invades any one from a Surfeit, or drinking of Wine, the cauſe is, that the little ſpaces in the medullary ſubſtance of the Brain, deſtinated for the motions of the Spirits, are too much obſtructed by a Narcotick or a watry humor: certain reliques of which, being reſolved into vapor, and thruſt out from the company of the Spirits, do often ſweat out, or drop into this *Vacuum* or empty ſpace.

After this manner, it may be believed concerning the Ventricles of the Brain, or the empty ſpace left within its plicature or folding together. But in truth, becauſe this matter hath been very much controverted among Phyſicians of every Age, and the right deciſion of it ſeems to be of great moment, for the explicating the offices of the other parts of the Head; I will here compare together the reaſons for and againſt this Opinion, that we may at length give our Judgment of this Opinion, what may be either true, or moſt likely.

CHAP. XII.

It is inquired into, whether the ſerous Humors, heaped together within the Vacuity of the Brain, be ſent out by the Pituitary Glandula and the Sieve-like Bone, or not?

SInce Experience teſtifies, that the Serum and excrementitious, I may juſtly ſay morbifick, and oftentimes deadly Humors, are found frequently within theſe Ventricles of the Brain; we ought to enquire more diligently concerning their paſſage in and out: and the rather, for that it is very much doubted by ſome concerning the uſe of theſe Dens, nor are there wanting thoſe in this late Age, who have endeavoured to bring into vogue the ancient Opinion, though long ſince exploded, concerning the Spirits being begot in this place, and here exerciſed. I believe without doubting, for the reaſons before alledged, that the Spirits are not here begotten, nor exerciſed. and no leſs certain is it made by Experience, that the ſerous Colluvies is here often gathered together. This therefore only remains, that we ſhould ſee from whence, and how this flows hither, and then by what ways of Excretion the ſame ſhould be carried out.

As to the firſt, it is exceeding probable, that the ſerous *Latex*, which is the Vehicle of the Spirits newly produced, and is introduced together with them into the Pores of the Brain, after it is grown ſtale, and being attenuated into Vapour, doth diſtil forth into this Cavern, and there at laſt grows into a watry Humor: for otherwiſe what becomes of that Humor, or into what other Receptacle could it be derived? Beſides this ordinary, and I believe aſſiduous heaping together of the ſerous Colluvies within the Ventricles of the Brain, certainly it may be believed, that this kind of ſerous Humor is diſtilled out of the Glandula's inſerted in the *Choroeidal* infolding, being too much filled, into the Ventricles ſo called. I have often ſeen in a Dropſie the Glandula's of the Brain to be intumified, and like grains of Barley, burſting with too much wet, to become flaccid or withered, ſo that they could not retain the ſeroſities brought to them, but continually diſpoſed them into the Cavity beneath. Truly in a Dropſie of the Brain theſe Cavities or Ventricles are always ſeen to be full of water; the cauſe of which kind of diſtemper is, the blood being made more watry, puts off in its circulation a greater heap of Serum than the Veins can preſently carry back, or the Glandula's are able to receive and retain. For indeed, that the Serum, redounding on every ſide from the Veſſels, may the better ſlide into the Ventricles of the Brain, it is ſo ordered, that the greater infoldings of the Veſſels, with the inſerted Glandula's, ſhould be diſpoſed near all the Ventricles of the Head: becauſe, not only the infolding *Choroeides* is placed nigh the concourſe of the three Ventricles in the Brain, but another infolding, and no leſs noted, (which we have above deſcribed) with greater Glandula's, is ſet behind the Cerebel nigh the fourth Ventricle. In all, as it ſeems, for that end ſuch care is taken, that the watry part, coming from the blood, which is deſtinated either for the Brain or the Cerebel, for that it is not fit for the procreating of Spirits, might run into theſe infoldings of the Veſſels. But yet if a greater plenty of Serum be there laid up, than can be contained in them, or may be ſent away outwardly, whatever is ſuperfluous will ſlide into the Cavity underneath.

Hence

Hence it appears, from whence, and by what means the ſerous heap is gathered together within the Ventricles of the Brain: certainly to deny this going out is no other than to aſſert every ones Brain big with a Viper, which cannot be brought forth but by gnawing aſunder the bowels of its parent. Who ſhall lightly conſider the parts nigh the Ventricles, and their Fabricks, at firſt ſight only would ſwear with the Ancients, that the excrements of the Brain were laid aſide both lower through the Tunnel into the Palate, and above or more forward through the mammillary Proceſſes into the Noſtrils: But if the ſtructure of theſe parts be a little more diligently ſearched into, there is no body who preſently will not eaſily think, that by neither of theſe ways the excretion of any humor can be made; for neither from the pituitary Glandula through the Wedge-like bone, nor from the mammillary Proceſſes through the holes of the Sieve-like bone, is there any manifeſt aperture or opening to be perceived. But in very truth, we do ſuppoſe that the Brain is in ſome meaſure purged by both theſe Emunctories, for that objection may be anſwered, That the tranſlations of Humors in living Creatures are eaſily performed through places that ſeem impervious or unpaſſable; for while the Pores and paſſages in all the parts of a living Creature are dilated by ſpirit and heat, they tranſmit the rain of the Serum as through the fine texture of a woolen Cloth. This plainly appears from Athritick diſtempers, in which the ſerous *Latex* creeps by degrees through the nervous bodies, and paſſing through very ſmall ſpaces, makes a falling down of humors ſometimes upon theſe parts, and ſometimes upon others; ſo that it is obvious, that the Membranes and nervous Proceſſes drink in the ſerous humors like Sponges, and then by a light compreſſion render them by heaps, as is manifeſt in the Tooth-ach; for as often as a Bodkin or Inſtrument is put up into a hollow Tooth, clear water will come out plentifully. Indeed, in the body of a living Creature the paſſages of humors are not only made through open paſſages and chanels; but the thinner and more watry *Latex* creeps through the ſolid and ſmooth bodies of the Nerves, as alſo the Fibres and the Membranes, as through the holes of a Filtre, and ſo is transferred through imperceptible ſtraits from place to place. I ſometime knew in the Impoſtume of the Lungs the humor to have been derived through the Membranes growing to the *Pleura* from the bag into an Iſſue made in the ſide, and ſo the ſpitting ceaſing, the Diſeaſe that ſeemed otherwiſe incurable, was healed by ſuch a way of Evacuation. Why in like manner may we not ſuppoſe the ſerous humors falling down from the Ventricles of the Brain into the pituitary Glandula, and the mammillary Proceſſes to be carried away through the Nerves or Membranes paſſing through here or there?

Concerning the Tunnel, the thing is probable enough; becauſe the poſition and ſtructure of this ſeem to ſhew, that ſome humor is carried out of the Ventricles of the Brain towards the pituitary Glandula. For this part is ſo conſtituted, that a falling down of the humors may be made from every angle and receſs of the interior Brain and its Appendix into its aperture or opening. And as in ſeveral Animals, the figure and ſite of the Ventricles vary very much, (as we have already ſhewn) yet in every one of them all the Ventricles of the Head, whatſoever they be, have their openings gaping towards the Tunnel. But that this Kernel or Glandula, to which the paſſage of the Tunnel is inſerted, receives and carries out the ſerous humors, ſeems alſo to appear from hence; becauſe it admits, not only thoſe falling from the Brain into its Pores, but alſo thoſe ſecreted from the blood aſcending into the Brain: For that in many four-footed beaſts, certain Veſſels are inſerted to this Glandula from either Carotidick Artery, which intimately enters its ſubſtance: a ſign of which is, that Ink being injected into the Trunk of either Artery, dyes with a black colour the wonderful Net, if it be there, and oftner the interior ſubſtance of this Glandula: whence it may be argued, that the office of this Glandula is to receive the ſuperfluous ſeroſities; and it receives not only thoſe ſent away in the return from the Brain, but ſometimes preoccupies or prevents them, and is wont to derive them from the blood before it is carried to the Brain. And therefore this Glandula is very ſmall, if the ſuperfluities of the Serum be derived to it only from the Brain; but greater, if they come to it alſo from the blood, to wit, as it executes either one or a double office, as we have already ſhewn at large.

But as to what reſpects the way of paſſing through, to wit, by which the humors depoſited in this Glandula, are carried out, the vulgar Opinion is, that they do come away through the holes of the bone beneath into the Palate: wherefore in thoſe kind of Animals, who have the wonderful Net, and many of its ſhoots enter this Glandula, more holes are made in the underlying Bone. Further, if you take away the ditch or gutter of the Wedge-like bone, or the ſeat of this Glandula cut off from the Skull, and pour water upon its holes being made bare from the Membrane, it paſſing preſently through the ſubſtance of the whole bone, will ſuddenly ſtill forth through other holes lying open in the ſides of the bone. Yet this Experiment concludes nothing for the Opinion propoſed: becauſe theſe holes are wholly wanting in ſome Creatures, and very much in an humane Skull; in thoſe who have them, as in a Calf, eſpecially it is obſerved, that the ſame are filled by ſome hollow Veſſels; into which, if a black liquor be caſt by a Syringe, that paſſing through the ſubſtance of the bone, will go into many other Veſſels lying under the bone, and at length into the Trunk of the Jugular Vein; which certainly is a ſign that the humors are not carried from hence into the Palate. But as to the Veſſels which cover over the holes of the bone, and which more abundantly lye under the ſame, they ſeem to be either Veins or Lymphæducts.

But among theſe it is lawful to conjecture, the chief means of Excretion, whereby the ſerous humors, laid up in the pituitary Kernel, may be carried out; to wit, that they are remanded back from it, as from moſt other Glandula's or Kernels, into the maſs of blood. In a Calf the thing lies open

to ocular Inſpection, nor is it to be doubted of other Animals, who have the admirable Net: becauſe as the arterious branches, ſo alſo the veinous reach to this Glandula; which ſup up not only the humors depoſited from the Arteries, but alſo thoſe falling from the Ventricles of the Brain. Yea, it may be lawfully believed, that in a Man alſo, a Horſe, and in other Creatures, who want the ſtrange or wonderful Net, there are other Lymphæducts or Water-carriers, or ſuch kind of Veſſels, as are ſeen in the head of a Calf, that moſt certainly carry the humors from this Glandula. We cannot ſo eaſily find out their footſteps, becauſe, before theſe break out of their dens, the tracts of the Lymphæducts, if there be any, would vaniſh. Nor can we find out theſe Veſſels in all, as in a Calf, by injection; becauſe the holes of the bone, by which, as by the leading of a thread, the injection arrives at, and dyes the Veſſels, otherwiſe lying hid, are wanting in moſt. No doubt but time will render ſufficiently manifeſt the reductions of the humors from the pituitary Glandula in other living Creatures: in the mean time, it may be lawfully ſuſpected, for that the ſeroſities in ſome are remanded from thence into the bloody maſs, that in all it is done after the like or the ſame manner, although the ways of the paſſing do not yet ſufficiently lye open.

As to the other Emunctory of the Brain, to wit, whereby the ſerous humors, laid aſide from the Ventricles of the Brain into the mammillary Proceſſes, and thence are thought to be ſent away through the holes of the Sieve-like bone: truly, concerning this way of Excretion, it is much more to be doubted, becauſe theſe holes in the defunct being covered over and fully ſtuft, with the inſertions of the *Dura Mater* and nervous Fibres, ſent on either ſide from the mammillary Proceſs, tranſmit nothing of humor, how clear ſoever it be. Further, there is nothing more certain, than that the ſerous humors are preſſed out from the Glandula's and extremities of the Veſſels ending within the Noſtrils into their Caverns; ſo beſides that 'tis ſcarce poſſible for the humors to deſcend thither from the Brain, it is not abſolutely needful to ſuppoſe this ſort of means of Excretion. But that we may reaſon a little farther concerning theſe; if it may be lawful to argue from the proviſion, and from the effects of the parts, there is no reaſon but that I may probably believe, that ſome humors alſo do ſhower down from the Brain into the cavities of the Noſtrils: for it being ſuppoſed, that the ſerous humor paſſes through, not only open chanels, but the more ſtrict Pores and paſſages alſo of the Nerves, and creeping both through the Fibres and Membranes, as through the ſtrainings or holes of a Filter or Strainer, is carried from place to place, (which it were eaſie to demonſtrate) what ſhould hinder but that the ſame ſort of *Latex* may deſcend through the Fibres impacted in the holes of the ſtraining bone? For although in dead creatures thoſe parts ſeem to be impervious or unpaſſable, yet during the life of the Animal the paſſages and blind ways of the nervous bodies, being dilated by Spirit and Heat, moſt eaſily tranſmit a copious humor wherewith they are watered.

The Sieve-like Bone in divers Animals is variouſly perforated for the manifold neceſſity and difference of ſmelling. A Proceſs from the *Dura Mater* and manifold nervous Fibres paſs through every one of its holes, and beſmear the inſide of the Noſtrils. But as the impreſſions of ſenſible things, or ſenſible Species, continued as it were by the undulation or waving of the animal Spirits, aſcend through the paſſages of theſe bodies ſtretched out from the Organ towards the Senſory; ſo the humidities watring the ſame bodies, for as much as ſometimes they may be more ſuperfluous than uſual, may diſtil into the Noſtrils through the ſame ways. For indeed ſuch humors as are perpetually to be ſent away from the brain, ought ſo copiouſly to be poured upon the Organs of Smelling, as we ſhall ſhew hereafter, when we ſhall ſpeak particularly of the Smelling Nerves; in the mean time, that there is ſuch a way of Excretion opening into the Noſtrils, ſome obſervations, taken of ſick people troubled with Cephalick diſeaſes, do further perſwade. I have known ſome very obnoxious to the Scotomy and Vertiginous diſtempers, who had great plenty of clear water that diſtilled forth about the end of the Fit; by which kind of Evacuation, as it were Critical, the Fit was wont to be ended. Not long ſince, a Virgin living in this City, was afflicted a long time with a moſt cruel Head-ach, and in the midſt of her pain much and thin yellow Serum daily flowed out from her Noſtrils: the laſt Winter this Excretion ſtopped for ſome time, and then the ſick party growing worſe in her Head, fell into cruel Convulſions, with a ſtupidity; and within three days dyed Apoplectical. Her Head being opened, that kind of yellow *Latex* overflowed the deeper turnings and windings of the Brain, and its interior Cavity or Ventricles. I knew a Gentlewoman that was wont to be infeſted with a moſt cruel Head-ach, alſo with a *Vertigo*, and a frequent melting of the Animal Spirits, or Swooning away; who when ſhe began to be better after a grievous Fit, felt at firſt a creeping motion in the top of her Brain, as it were the ſliding down of water: then that motion paſſing a little more forwards and downwards, at length many drops of clear water diſtilled from her Noſtrils. This Symptom ſhe uſed to have ſo ordinarily, that the ſick Gentlewoman did not doubt but that this water ſtilled out from the Brain it ſelf. I could here bring many other reaſons, which might ſeem to perſwade, that the Ventricles of the Brain, or the Cavity made by the complicature or folding up of its border, is a mere ſink of the excrementitious Humor; and that the humors there congeſted, are purged out by the Noſe and Palate: But it is time for us to haſten to other matters, and to paſs from the Brain, properly ſo called, to its Appendix, *viz.* the oblong Marrow and the Cerebel.

CHAP.

CHAP. XIII.

The Actions and Uſes of the oblong Marrow, and ſome of its Parts are unfolded.

WE will paſs now from the Brain to the explication of its Trunk, to which both it and the Cerebel do grow like Muſhrooms or large Excreſcences. This part is commonly called the Oblong Marrow; under which name we comprehend all that ſubſtance which reaches from the inmoſt Cavity of the callous body, and conjuncture in the Baſis of the Head, to the hole of the hinder part of the Head; where the ſame ſubſtance, being yet farther continued, ends in the ſpinal Marrow. The ſuperficies of the oblong Marrow, though it be made unequal with ſome protuberances and proceſſes, yet it is not varlegated or garniſhed with any turnings about, and involutions, as it is in the Brain and Cerebel; neither is its exterior and cortical ſubſtance, or of an Aſh-colour, and the interior, medullar or marrowy and white; but all its frame or ſubſtance is in a ſort marrowy or medullous; nor does it however appear pure and bright, but much darkened with fibres and hairs variouſly ſtretched forth, and diverſly going out. To wit, its fibres being figured in various places, after a diverſe manner, in ſome places they are found chamfered, and as it were beamy, in others direct or ſtretched out at length, and in other places again circular.

The Figure of this is forked, and as it were like the Poets *Parnaſſus*, ſeems like the letter Y: for its ſhanks ariſing more forward from either Hemiſphere of the Brain, and inclining one to another, grow together near the centre of the Skull into one and the ſame Trunk; which notwithſtanding, a line being brought through the midſt, ſeems to be made as it were out of two ſtalks, and thoſe to be diſtinguiſhed in its whole proceſs.

The oblong Marrow ſeems to be a broad or high Road, into which the Animal Spirits perpetually flow from their double Fountain, to wit, the Brain and the Cerebel, to be derived from thence into all the nervous parts of the whole Body; which Spirits, whilſt they are orderly diſpoſed in this common paſſage, as it were by ſeries and orders, carry a twofold aſpect; to wit, they are directed either outward towards the Nerves, when they exert the loco-motive Faculty, or they look inward towards their Fountains, when the acts of ſenſe, or rather the apprehenſions of ſenſible things are performed.

Within this open way, a more large and greatly open path leads ſtraight to the ſpinal Marrow, through which the Spirits flow forth to the Nerves, the Executors of ſpontaneous motion in moſt Members. In the mean time, out of the ſame tract of the oblong Marrow, leſſer paths are carried outwardly, here and there, by particular Nerves, ariſing from the ſame, within the Skull. Alſo beſides, many diverting places, *viz.* various proceſſes and protuberances grow to this medullary Trunk, into which, the Spirits deſtinated to ſome peculiar offices, go apart: leſt that all the Spirits travellinng this way, and that way in the ſame path, ſhould meet one the other and diſturb one anothers offices.

Whilſt after this manner, for the performing the acts of Motion and Senſe, we ſuppoſe the Animal Spirits to be expatiated within the oblong Marrow; we affirm, that they are not there begotten, but only exetciſed. For indeed, they being created only in the Brain and Cerebel, as they proceed from this or that, they perform theioffices, either of a merely involuntary Function, or elſe of a ſpontaneous, as ſhall be ſhewed more largely hererſter.

But that we may unfold here all things which belong to the oblong Marrow, I ſhall mete it forth from its firſt coming out to the end of its race, and handle its ſeveral *Stadia*, diverting places, and croſs ways. Where the callous Body is thought to end, the oblong Marrow begins, to wit, when the medullar ſubſtance of the Brain is thickeſt nigh the boſſes or knobs of either Hemiſphere, a body of a whitiſh colour and ſomewhat darkned or obſcured, and ſtreaked like Ivory, is joyned to that Marrow on both ſides. Theſe two bodies are the extremities or tops of the ſhanks of the oblong Marrow; between which and the Brain there are nigh and very immediate commerces. Either of theſe ſeems as it were a Cylinder rolled about into an Orb, which nevertheleſs conſtitutes the top of either ſhank, not ſpherical, but oval, and ſomething bent downward in the hinder part. A more large portion of its ſuperficies is joyned to the medullar ſubſtance of the Brain; but yet ſome part of it, being free from the coheſion with the Brain, ſhews it ſelf apart, and makes that protuberance ſhewing it ſelf in either lateral Ventricle. Theſe bodies, if they ſhould be diſſected along through the middle, appear marked, with medullar ſtreaks, as it were rays or beams; which ſort of chamferings or ſtreaks have a double aſpect or tendency; to wit, ſome deſcend from the top of this body, as if they were tracts from the Brain into the oblong Marrow; and others aſcend from the lower part, and meet the aforeſaid, as if they were paths of the Spirits from the oblong Marrow into the Brain. And it is worth obſervation, that in the whole Head beſides there is no part found chamfered or ſtreaked after the like manner.

If the uſe of theſe be inquired into, this preſently occurs, that theſe bodies, placed between the Brain and its Appendix, are the great and common diverting places of either; to wit, which receive whatſoever impulſes or forces of the Animal Spirits are ſent from either, and communicate them preſently to the other: Or that I may ſpeak more plainly, this part is the common Senſory, to wit, as *Ariſtotle* ſaith, τὸ πρῶτον αἰσθητήριον, the firſt Senſory that receives the ſtrokes of all ſenſible things, dilated from the Nerves of every Organ, and ſo cauſes the perception of every ſenſe; which kind of ſtrokes of ſenſible things, when from hence they are paſſed further into the Brain, preſently Imagination ſucceeds the Senſe: and further, theſe bodies, as they receive the forces of all the Senſes, ſo alſo the firſt inſtincts of ſpontaneous local motions. To wit, as often as the Appetite diſcerns any thing to be done, preſently the reciprocal tendencies of the Animal Spirits, that is, from the Brain into theſe parts, are diſpoſed here to act the conceptions of motions coming from any part or member. For here, as in a moſt famous Mart, the animal Spirits, preparing for the performance of the thing willed, are directed into appropriate Nerves. That it is ſo, it appears, becauſe every influence from the Brain into the nervous ſtock, and on the contrary, from this into that, and the mutual commerce of the animal Spirits, muſt of neceſſity paſs through theſe bodies. Wherefore all the Nerves, alſo thoſe which belong to the more inward Organs of the Senſes, ariſe behind theſe chamfered bodies. For the Optick and ſmelling Nerves creep through the ſuperficies of the Brain by a long paſſage and windings about, that they might be inſerted below this part of the oblong Marrow.

For indeed, the Species of ſenſible things, received by thoſe Nerves, might more immediately be carried to the middle of the Brain, unleſs that they ought firſt to be ſtaid at this Senſory. Further, we may lawfully conjecture, that theſe parts perform the aforeſaid office from their chamfered, and as it were beamy contexture: For as thoſe chamfering with which theſe bodies are marked, (as we but now intimated) are of a double kind, to wit, ſome deſcending, which look from the Brain towards the oblong Marrow: and others aſcending, which are carried diſtinctly from this towards that, it may be lawfully concluded, that in theſe carried upwards, the impreſſions of ſenſible things are perceived; and in thoſe tending downwards are performed the Inſtincts of Motions.

Further, that theſe bodies, as was ſaid, perform the offices of the firſt Senſory, beſides the fabrick of their parts, and the Analogy to be collected thence of their uſe, it ſeems yet more certainly to appear from ſome Obſervations concerning theſe chamfered bodies, after what manner they are affected in Paralytick diſeaſes. For as often as I have opened the bodies of thoſe who dyed of a long Palſie, and moſt grievous reſolution of the Nerves, I always found theſe bodies leſs firm than others in the Brain, diſcoloured like filth or dirt, and many chamferings obliterated. Further, in Whelps newly littered, that want their ſight, and hardly perform the other faculties of motion and ſenſe, theſe ſtreaks or chamferings, being ſcarce wholly formed, appear only rude.

The chamfered Bodies, inclining one to another near their blunt and greater angles, are almoſt contiguous; but that the Trunk of the *Fornix* intervenes with its twofold Root: yet in that place where the two Roots of the *Fornix*, being ſent ſtraight down, are inſerted into the callous body, a tranſverſe medullar proceſs, like a great Nerve, ſtretched from one chamfered body to the other, as it were joyns the ſame, and makes them to communicate one with the other. Certainly, this joyned together of the chamfered bodies is made, that their actions and paſſions may not be double: but though the ſpecies of the ſenſible object or conceptions of the motions to be performed, coming from the Brain or Senſory being double, are carried alſo double to the firſt Senſory; yet for as much as either ſubſtanc or frame of this, communicates with the other, every impreſſion coming this or that way, becomes ſtill one and the ſame. For it may be obſerved, in the whole Head, that though almoſt all things are double, yet each of them communicate among themſelves, either by a contiguity, or by proceſſes ſent forth. And ſo as by the duplication of it, care is taken againſt the abſolute privation or defect of the act, ſo the joyning together of its duplicature provides againſt the empty or confuſe multiplication of the ſame ſpecies.

After this manner, the chamfered bodies in Man and four-footed Beaſts are conſtantly found of the ſame ſpecies or form, and in every one of them, figured after the ſame manner; and are as it were the Joynts that joyn the brain to the ſhanks of the oblong Marrow. But we have already ſhewn, that in Fowls and Fiſhes, whoſe brains being alike, differ from thoſe of men and four-footed beaſts, the thing is ſomewhat otherwiſe: For in Fowls the callous body is wanting to the brain; but what ſerves inſtead of it, is found in the oblong Marrow, to wit, two little Ventricles ſhew themſelves nigh the chambers of the Optick Nerves, which are arched or chamber'd with a whitiſh ſubſtance, ſuch as the callous body is in man or four-footed beaſts. Then on the contrary, the chamfered bodies, or the parts which ſerve in their ſtead, in Fowls, are not a portion of the oblong Marrow after the uſual manner, but are entred into the Brain it ſelf. For near the fiſſure of the Brain, two Membranes being marked with medullar chamferings, both diſtinguiſh either Hemiſphere of the Brain, and cover over its Ventricles. The ſtreaks or rays of either Membrane deſcend, and being concentred about the Baſis of the Brain, go together into a medullary proceſs, which is inſerted on both ſides to the oblong Marrow. So theſe parts, *viz.* the callous body, in which the animal Spirits are expanded, and the chamfered bodies, in which their paſſing to and fro is inſtituted, ſeem to be tranſpoſed in the head of Fowls. The reaſon whereof, (as I elſewhere hinted) unleſs I be deceived, is this: becauſe theſe Animals are of leſs excellency in imagination and Memory than four-footed Beaſts; yea alſo, for that the ſenſe and motion of them are their chief

Facul-

Faculties: therefore for the exerciſes of theſe to be performed with a greater expanſion of Spirits, the callous body is transferred into the oblong Marrow, and in its place the chamfered bodies are removed into the Brain.

About the lower end of either chamfered body the ſmelling Nerves are inſerted. For you may take notice, that the mammillary Proceſſes, a little more obſcure in man, but much more conſpicuous in brute Animals, who are endued with a more remarkable ſenſe of ſmelling, do paſs into firm and plainly whitiſh bodies of Nerves, which being dilated or brought nigh the lateral turnings and windings of the Brain, are implanted into the oblong Marrow on either ſide about the lower angle of either Ventricle behind the chamfered bodies; yet ſo, that the Tube or Pipe of either Nerve may open into the Cavity of the Ventricle, as we before ſhewed. After this manner theſe Nerves are carried by a long journey from the fore-part of the Brain, that they may bring the ſenſible ſpecies to the chamfered body, as to the common Senſory, firſt and rather than to the Brain. But we ſhall ſpeak of the ſmelling Nerves more particularly hereafter.

Where theſe chamfered Bodies end from either ſide, a marrowy ſubſtance ſucceeds, which being ſomewhat of a darkiſh colour going forward for ſome ſpace, is diſtinguiſhed by a peculiar bending forward from the other contiguous parts. This *Galen* (perhaps not improperly) calls the Chambers of the Optick Nerves; for in this place the Optick Nerves ſhewing themſelves from the higheſt region of either ſide, being carried downward with a certain compaſs, are united about the Tunnel. Then being divided again, and carried a little further, enter the Skull, going ſtraight forward to either Senſory. The growing together of theſe Nerves, and their being again ſeparated, ſeems to be ordained for this end, that the viſible ſpecies, received from either Eye, might appear ſtill the ſame, and not double; for this conjunction of the twofold Organ frames the double image into one; which once united, when afterwards it is carried to either ſide of the common Senſory, for that it is on both ſides alike, appears ſtill the ſame. If at any time, through drunkenneſs, or a diſtortion of the Eyes, the object appears double, and two Lights upon a Table, it is becauſe the image of the ſame thing is received after a different manner by one Eye than the other, for that reaſon the objects are repreſented like two diſtinct things. For that this Eye is diſtorted after one manner, and that after another, the ſame Species, coming to either Pupil by a diverſe angle of incidence, appears diverſe or double. There is another reaſon of the coalition of the Optick Nerves, to wit, that one Eye being hurt, all the viſible Animal Spirits might be beſtowed on the other. Further, for that theſe Nerves are carried with a long paſſage, their uniting helps to their mutual ſtrength and ſupport.

Whereas the Optick Nerves ariſe here from the oblong Marrow, all or its moſt intimate ſubſtance is not beſtowed upon them; but theſe Nerves are inſerted into the medullar Trunk, as branches of a Tree to the ſtock, that ſo they may receive by that means the influence of the Spirits, and by this way tranſmit the Species of viſible Things. In the mean time, this more inward ſubſtance of the oblong Marrow is the common paſſage both to the Eyes and to the other nervous Syſtem ariſing more backward: through which, by the going and returning to and fro of the animal Spirits, the impulſes of ſenſible things, and the inſtincts of Motions between the Brain and the other nervous parts, which depend upon it, are performed. Foraſmuch as the ſmelling and ſeeing Nerves ariſe ſo near the chamfered bodies, the reaſon hence is plain, why odors or the objects of the ſenſe of ſmelling ſo ſtrike the Brain it ſelf, and immediately affect it; alſo why there is ſo exceeding ſwift a communication between Sight and Imagination.

Concerning the Optick Nerves in a Man, (which alſo in ſome meaſure is after the ſame manner in other living Creatures) we ſhall advertiſe you, that when they, after their uniting or mixing together, being preſently again ſeparated, do go out of the Skull, the ſanguiferous Veſſels going out of the Skull with them, and following either Nerve even to the Baſis of the Eye, are knit into the Trunk of either There is a noted ſhoot of the Artery deſtinated to this office, carried from the anterior branches of the *Carotides*. Hence, as I ſuppoſe, a reaſon may be given, wherefore, when by drinking or more plentiful eating, a ſleepineſs is cauſed, preſently a great heavineſs, and as it were an oppreſſion, is felt about the Eyes. For when the blood, very much boiling up, fills above meaſure the Veſſels watering the Brain, and by diſtending them, obſtructs the Pores of the Brain, thoſe Nerves alſo from the blood in like manner boiling up within the Optick Veſſels, are preſſed together in their whole paſſage.

In Fowls and Fiſhes this chamber of the Optick Nerves, bunching out with a great bulk, is not much leſs than the Brain it ſelf; for, as we but now intimated, what is inſtead of the callous body is placed here; and in this place the Animal Spirits ſeem to have their chief Mart or Empory in a moſt large medullar chamber, or the Sphere of their Expanſion. And ſo, when from hence the Animal Spirits are derived from ſo full and plentiful a Store-hoſe, it is for that reaſon Fowls are furniſhed with ſo curious an Eye, and with ſo highly perſpicacious and acute a ſight. And the ſame perhaps may hold concerning Fiſhes, if that we conſider the ſight in theſe is performed in a thicker Medium, and often double.

In ſome Animals, in the midſt of theſe chambers of either Optick Nerve, the ſhanks of the oblong Marrow a little opening, leave a chink or aperture, which receiving the ſeroſities coming from every region of the Brain and its Appendix, ſends them through the Tunnel into the pituitary Glandula.

There is no need that we ſhould diſcourſe much here of the Tunnel and the pituitary Glandula, becauſe, already ſpeaking of the Ventricles of the Brain, or the empty ſpace left within its plicature, we fell occaſionally on the conſideration of both theſe: where we ſhewed, that the ſerous humors, which were

wont

wont to be heaped together within many places of the Brain and of its Appendix, do all ſlide down on every ſide from each angle and receſs of it into the ſteep opening of the Tunnel; and ſo there is a neceſſity that they ſhould be poured out by it into the pituitary Glandula. Further, it is manifeſt, that this Glandula, in ſome Animals, is charged with a double office; to wit, as it receives the ſerоſities ſent from above from the Brain, ſo alſo it ſeparates the humors from the blood brought to the ſame from the wonderful Net by the Arteries, and prepoſſeſſing them, imbibes them before their ingreſs to the Brain. Wherefore this part is furniſhed with a ſubſtance of a double kind, *viz.* one reddiſh, more thin, and interwoven with Blood-carrying Veſſels, which conſtitutes either ſide of it; and the other more white placed in the middle, to which the Tunnel is inſerted.

But having ſhewn, that this Glandula receives the humors ſo brought by a double Tribute, we did diligently inquire concerning the ways and means whereby they are at length carried away from thence, and as it appears by an Experiment, that there is a paſſage open from this Glandula into the Veſſels lying underneath the bone, and from thence into the Jugular Veins, we affirmed, that 'twas moſt likely, that the humors to be carried away from this Glandula, (after the manner of others) may be reduced at laſt into the bloody maſs. I ſhall not add any more concerning theſe things, but proceed to the other parts of the oblong Marrow. But that, what hath been ſaid, concerning the ſhanks of the oblong Marrow, and their tops, *viz.* the chamfered bodies, may be the better underſtood, it will ſeem to the purpoſe that we repreſent the Images of all theſe in the following Figure.

The Eighth Figure.

REpreſents the oblong Marrow taken out of the Head of a Sheep with the Brain cut off and removed, and with the Cerebel and one ſtreaked Body cut in two in the middle, and other things chiefly belonging to the medullar Trunk.

AA. *The chamfered Body cut in two in the midſt, that its marrowy chamferings may appear.*
B. *The other chamfered Body whole covered with the Choroeidal Infolding with the extreme portion of the callous Body* CC. *ſticking to the ſame.*
CC. *The brim or extremity of the callous Body cleaving to the chamfered Body.*
D. *The Baſis of the* Fornix.
E. *The right wing of the Chorotidal Infolding.*
F. *The paſſage of the Veins being ſtretched out from the fourth boſom, which being preſently forked, conſtitutes the veinous portion of either wing of the Choroeidal Infolding; under the beginning of this paſſage, very much beſet with Fibres and ſanguiferous Veſſels, the Pineal Glandula lyes hid.*
G. *The hole or chink leading to the Tunnel.*
HH. *The chambers of the Optick Nerves.*
II. *The medullary proceſſes, or the ways of paſſage which lead from the medullar ſtock into the orbicular Protuberances.*
KK. *The Buttock-form orbicular Protuberances.*
LL. *The leſſer Protuberances called* Teſtes.
M. *The meeting together of the Proceſſes aſcending obliquely from the* Teſtes *into the Cerebel.*
N. *The hole of the lower Ventricle lying under the orbicular Protuberances.*
OO. *The pathetick Nerves of the Eyes.*
PP. *The medullary Proceſſes ſtretched out from the* Teſtes *into the Cerebel.*
QQ. *Other medullar Proceſſes, which being ſent from the Cerebel towards the oblong Marrow, compaſs about its ſtock, and conſtitute the annular or ringy Protuberance.*
RR. *The loweſt or third Proceſſes of the Cerebel, which being inſerted to the medullar Trunk, become additional cords or ſtrings of it.*
SS. *The medullar Ramifications or Branchings of the Cerebel.*
TT. *The middle marrows of either Cerebel in which its three medullary Proceſſes, conſtituting either little foot of it, grow together.*
V. *The Ditch conſtituting the fourth Ventricle in the medullar Trunk.*
X. *The extremity of the oblong Marrow about to end in the Spinal.*

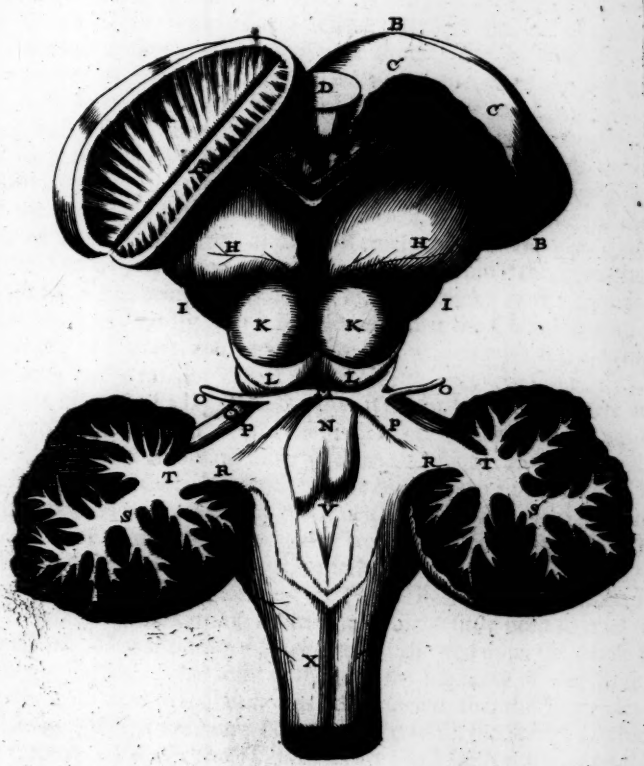
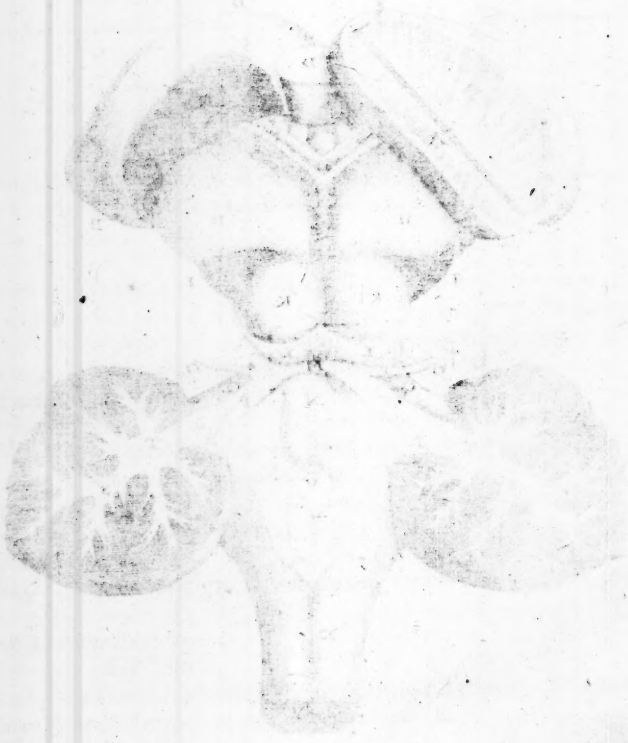
II. p. 86





CHAP. XIV.

Of the Uſes of the Pineal Glandula and the Choroeidal Infolding; alſo of the orbicular Prominences which are commonly called Nates *and* Teſtes; *and other Parts which ſeem to be dependences of them.*

BElow the Chambers of the Optick Nerves in a common Valley which lyes between the tops of theſe and the Buttock-form Prominences, is placed the Pineal Glandula or Kernel in form of a Pine-apple, called alſo *Conarium*; this is not only found in Man and four-footed Beaſts, but Fowls and Fiſhes alſo are endued with the ſame. Wherefore, although from hence it may be concluded, that this is of neceſſary uſe; yet we can ſcarce believe this to be the ſeat of the Soul, or its chief Faculties do ariſe from it; becauſe Animals, which ſeem to be almoſt quite deſtitute of Imagination, Memory, and other ſuperior Powers of the Soul, have this Glandula or Kernel large and fair enough.

It is obſerved in all Animals of every kind and form, that to this Glandula, always placed nigh the holes or paſſages, open to the Tunnel, the Choroeidal Infolding is continually joyned; yea this infolding (ſeeming to hang from the Pineal Kernel ſuſtaining its middle Proceſs, as it were by a nail or haſp, from thence) is divided into two wings ſtretching out on either ſide upon the ſhanks of the oblong marrow, Wherefore we may juſtly ſuſpect, that this Glandula is chiefly made for the ſake of this infolding; and that the office of it is no other than of other Kernels, which are placed nigh the concourſe of the ſanguiferous Veſſels: to wit, that it may receive and retain within it the ſerous humors depoſited from the arterious blood, till the Veins being emptied, may ſup them back, or the Lymphæducts (if there be any there) may convey them outwardly. For it is obſerved, that the Choroeidal infolding is beſet with very many leſſer Glandula's or Kernels, and every where interwoven with them, which imbibe the Serum ſecreted from the blood, in the ſmaller Veſſels; therefore for this very ſame office, where all the Veſſels concur, this Kernel is placed, of a bigger bulk, that it might be able to receive and contain the ſeroſities there plentifully depoſited. Moreover, it is of no ſmall moment, that this Glandula ſuſtains and keeps duly ſtretched out the *Choroeidal* infolding otherwiſe hanging looſe, and apt to fall down into it ſelf, or at leaſt to ſlide out of its proper place. Wherefore I have often taken notice in the Dropſie of the Brain, that this *Glandula* being looſned at the roots by too much moiſture, and often broken off, and removed from its place, the *Choroeidal* infolding hath ſlid together from its proper expanſion, and ſlip'd down lower, and alſo ſuffered its Veſſels to be folded together diſorderly.

From theſe things thus premiſed concerning the Pineal Glandula, it will not be difficult to aſſign alſo the uſe of the *Choroeidol* infolding: Concerning which there will be little need to refel that Opinion of the common ſort, which aſſerts, That the animal Spirits, to be beſtowed upon the whole Brain, are begot in this infolding: becauſe the Veſſels of this inſtil nothing to the ſubſtance of the Brain or its Appendix, for that they are no where inſerted to it; but it was before ſhewn, that the Ventricles of the Brain, or the Cavity in which theſe ſame Veſſels are hung, do not at all contain the Spirits; which further appears more plain, becauſe in Cephalick diſeaſes thoſe Ventricles are filled with water, and the continuity of the infolding is diſſolved by too much moiſture, when in the mean time the ſick are indifferently ſtrong in the exerciſe of the animal Faculties.

But indeed we ſuppoſe, that this infolding ſerves for a twofold office: *viz.* Firſt, that the more watry part of the blood, deſtinated for the Brain, might be ſent away into its Veſſels, to the end, that the remaining portion of the bloody *Latex* might become more pure and free from dregs to be diſtilled forth into Spirits; even as is wont to be done in a Chymical Diſtillation, to wit, when there is a peculiar Receiver fitted for the receiving of the Phlegm by it ſelf, more ſincere, pure, and ſubtil Spirits are inſtilled into the other more noted Receiver. The more watry blood entring the arterious Veſſels of this infolding, being carried from them into the Veins, is remanded back towards the Heart. In the mean time, leſt the Serum, too much redounding, and boiling up in theſe Veſſels, might hinder circulation, its ſuperfluities are received for ſome time both by the leſſer Glandula's thickly inſerted, and alſo by the pineal Kernel.

The other and no leſs noted uſe of this Infolding, is to conſerve the heat of the blood boiling within the complications of the Veſſels, and as it were circulating about, being excited as from a fire-place within the infolding of the Brain. For though the *Pia Mater* need not implant thick ſhoots of Veſſels in the callous Body and inward Marrows of the Brain, for that they are rather dedicated to the Exerciſe than to the Generation of the animal Spirits; yet that the heat requiſite for the circulation of the Spirit, might be kept conſtantly in that place, this infolding is hung upon the whole neighbourhood. For as the blood, aggeſted or heaped together within the Cavities of the Boſoms, is inſtead of an

hot Bath, whereby the animal Spirits are diſtilled plentifully into the outmoſt and cortical part of the brain; ſo the blood contained within the ſmall Veſſels of this infolding, ſeems to be in the place of a leſſer and more temperate Bath, whereby the ſame Spirits might be fitly circulated in the more inward and medullar ſubſtance.

Laſtly, Another reaſon may alſo be given, why the Choroeidal infolding is found always within the Ventricles or Cavity of the Brain, made by its infolding, and after what manner ſoever figur'd; to wit, that another ſort of commodity might reſult from thence; that when the Veſſels of that infolding, carrying too watry blood, lay aſide more Serum than the Glandula's are able to receive or contain, whas is ſuperfluous might ſlide down opportunely into the underlying Cavity, as into a Sink. Wherefore the *Pineal Glandula*, though ſet in a more eminent place, is however placed always near the hole or paſſage that lyes open towards the Tunnel in every Brain.

Next to the Pineal Kernel are found in the upper ſuperficies of the oblong Marrow certain noted Prominences, which are commonly called *Nates* and *Teſtes*. Theſe being placed naar together, do conſtitute as it were four Mole-hills, which yet are joyned one to another by certain proceſſes. Beneath theſe Mole-hills, or rather between the joyning of them and the runk of the oblong Marrow, placed underneath, a narrow and long Cavity or Den is left, which by ſome Anatomiſts is called the fourth Ventricle; but according to others later, who place the fourth Ventricle under the Cerebel, this Cavity is affirmed to be a paſſage to it.

The hinder extremity of this Den ends nigh the beginning of the fourth Ventricle; the more fore-extremity of it opens before the former Mole-hils or little bulkings out, called *Nates*. From the midſt of this Cavity or narrow Den a paſſage goes ſtraight to the Tunnel. It is very much controverted among Anatomiſts concerning the ſite of theſe parts, and of their dependency on one another, and of other parts, and of their uſe: Concerning which this is firſt to be noted, as we hinted above, that theſe four Protuberances are far greater in ſome brute Animals than in a Man, as in a Sheep, Calf, Goat, and the like; alſo in a ſound dry, and old Head they are more conſpicuous, and their proceſſes, joynings and habitudes may be more eaſily noted than in a younger, moiſt, or otherwiſe ſickly brain. Indeed the uſe of theſe (unleſs my conjecture deceives me) ſeems far more noble, than that they ſhould deſerve thoſe vile names of *Nates* and *Teſtes*, Buttocks and Teſticles.

Notwithſtanding, to what office theſe parts were deſigned, neither have the ancient Anatomiſts delivered, nor will it, by the help of Reaſon, be eaſie to gueſs for certain. We have already ſhewn, that theſe aforeſaid Prominences ought not to be taken for the two ſhanks either of the Brain or Cerebel bending back one towards another, and ſo growing together into the oblong Marrow. For although from this ſuppoſition a very neat Hypotheſis may be made for the œconomy of the animal Function, to wit, by affirming that theſe double ſhanks, on either ſide, were ſo many diſtinct ways of paſſage through which the animal Spirits, for the performing of motions, flowed from the Brain and Cerebel into the oblong Marrow, and returned thence from this into thoſe for the performing the acts of the Senſes: yet from our Method of Diſſecting it plainly appears, that the brain is not fixed to the oblong Marrow nigh this place, but far above it; ſo that indeed the anterior Prominences, unleſs mediately only, *viz.* by the chamfered bodies, receive not any portion of the medullar ſtock, or any influence from the brain, nor can have any dependency from it. Beſides, if the Protuberances called *Nates* were ſhanks of the brain, why ſhould the ſame be in man, (he having got the greateſt brain, the leaſt) or at leaſt leſſer than in moſt other living Creatures? Then between the Prominences called *Teſtes* and the Cerebel, although there happens a certain communication; yet it ſeems that there lyes open a paſſage from thoſe little lumps into the Cerebel, and not from this, through them into the oblong Marrow. For out of theſe aforeſaid Prominences a medullar Proceſs aſcends obliquely one either ſide into the Cerebel, by whoſe paſſage the animal Spirits, tending frome one ſtage to the other, cauſe a mutual commerce between thoſe parts and the Cerebel: But indeed the Proceſſes which lead from the Cerebel into the oblong Marrow, and carry to it its influences, being diſtinct from the former, ſtand ſomewhat lower, as ſhall be more clearly ſhewn hereafter, when we ſhall ſpeak of the Cerebel.

But in the mean time, concerning the offices and uſes to which the aforeſaid Protuberances ſerve, we ſhall make this conjecture. The animal Spirits perpetually flow out and leap back again from the fountain the brain into the oblong marrow, ſo that there may be had a conſtant commerce between the brain and many organs of ſenſe and ſpontaneous motion: from which thoſe parts are entertained which perform their actions, not at the beck of the Appetite, but either by the inſtinct of Nature, or the blind impulſe of the Paſſions; for ſuch receive wholly their influences from the Cerebel, as afterwards ſhall be more fully ſhewed. Whilſt therefore the Spirits, flowing from the brain, abound in the oblong marrow, it is fit that ſome of them ſhould be carried from thence into the Cerebel: (for what uſes this ought to be done, ſhall be told by and by) wherefore from either ſide of the oblong marrow a Protuberance grows forth, into which indeed the Spirits deſigned for the Cerebel, may go apart from the common paſſage of the oblong marrow; and theſe Prominences are the former, which are commonly called *Nates*, and as we have ſaid, are far greater in moſt brute Animals than in Man (the reaſon of which ſhall be declared anon.) The other hinder Protuberances, commonly called *Teſtes*, grow to theſe former, and are only certain Epiphyſes or Excreſcences of them, as it were the heads of the medullary Proceſſes, which are from thence carried by an oblique aſcent into the Cerebel; for when the animal Spirits

aſcend

aſcend from the former Prominences into the Cerebel, they enter theſe latter firſt, as it were the more large beginnings or entrances of their paſſage, from whence they go forward by the paſſage of the medullar Proceſſes into the Cerebel.

Beſides we may take notice, that when the animal Spirits are carried out of the oblong marrow into the greater natiform Prominences to be derived towards the Cerebel, they, according to their cuſtom, (as often as they tend towards the common Senſory from a double Organ of any Faculty) ought to be confounded and mingled together before they enter the Cerebel: wherefore both the firſt Prominences, and alſo the ſecond growing to them are joyned together with certain Proceſſes like wings reaching one another; which connexion indeed of them, becauſe it ought to be diſtinguiſhed every where from the medullar Trunk lying under it, hence, from the ſeparation or empty ſpace that comes between the oblong marrow and the growing together of the Prominences, that cavity ariſes, which is by ſome called the fourth Ventricle, and by others the paſſage to it.

If it be yet farther inquired, to what end the animal Spirits are carried by this by-paſſage from the common paſſage of the oblong marrow into the Cerebel, and thence back again; I ſay, that this is done for a twofold reſpect, *viz.* both that the Paſſions or Affections of the ſenſitive Soul, begun from the brain, may be tranſmitted to the *Præcordia* and *Viſcera*; then ſecondly, that the natural Inſtincts, excited in the *Præcordia* and *Viſcera*, might be communicated to the brain. Theſe reciprocal commerces which are had between the Brain and the Organs of involuntary Functions, ought to be inſtituted or performed by this private paſſage, leſt otherwiſe the exerciſes of theſe involuntary Faculties ſhould very much diſturb the acts of the outward Senſes, or the intentions of ſpontaneous motions.

As to the firſt, it is obſerved, that by every paſſion of the ſenſitive Soul, as from Anger, Sadneſs, Pleaſure, and other Affections, the *Præcordia* are diſturbed, whether we will or no; which variouſly dilate or conſtrain themſelves, and ſo ſtir up in the blood divers fluctuations. Moreover, from this kind of force of the Paſſions the countenance or the aſpects of the Face are wont to be altered and diſtorted after various ways. The reaſon of all theſe ſeems to be, becauſe when the animal Spirits, exiſting within the Brain, are moved according to the Idea of the conceived Paſſion, the other Spirits alſo flowing within theſe diverting places, being in like manner moved, affect the Cerebel, and that coming between, the original of the Nerves, ſerving to the *Præcordia*, *Viſcera*, and Muſcles of the Face, and ſo the parts to which thoſe Nerves are diſtributed, are alſo ſtirred up or provoked into motions anſwerable to the ſame paſſion.

But the aforeſaid Prominences and their dependences ſerve no leſs alſo for the conveying of the impreſſions of natural Inſtincts to the Brain, that from thence the Appetite and local motions might preſently be retorted; by which all the exigencies or wants perceived by the *Præcordia* or *Viſcera* might be ſupplied. When in a young one newly born the ſtomach crys out for hunger, the Inſtinct of this is carried by the paſſage of the Nerves to the Cerebel, and from thence by the medullar Proceſſes to theſe Protuberances; and the Spirits there inhabiting, form the Idea of the Impreſſion, and carry it to the brain, wherein preſently, without any previous knowledge or experience, ſuch kind of conceptions of the Soul are ſtirred up, that every little living Creature preſently ſeeks out the Mothers breaſts and ſucks.

But it may be objected, it does not ſeem of neceſſity we ſhould ſuppoſe theſe kind of acts of the Paſſions and Inſtincts to be made apart in this by-place, for why are not the commerces of the animal Spirits ordained by the influence from the Brain into the Nerves leading to the *Præcordia*, and ſo back again through the common paſſage of the oblong Marrow? But to that it may be readily anſwered, That this reciprocal motion of the Spirits ought to be made through the middle region of the Cerebel, from one ſtage to another for the exerciſe of theſe Faculties: And therefore, (ſince that all manner of communication between the Brain and Cerebel is performed by theſe Prominences) there ſhould alſo be had a paſſage by the ſame way between this and the Organs of the Functions merely natural. Beſides, if the rage or furious motions of the Paſſions and Inſtincts ſhould be carried in the ſame path in which the forces of ſenſible things are carried, their acts might be greatly confounded by the mutual meeting or gathering together of the animal Spirits. But this kind of Hypotheſis concerning the Acts and Progreſs of the Paſſions and natural Inſtincts, ſhall be made more clear afterwards, when we deſign the Actions and Uſes of the Cerebel, and of the other parts, which in like manner ſeem to be deſtinated to the ſame offices with theſe Protuberances.

In the mean time, what we have affirmed, that the latter Prominences are only Additionals or Excreſcences of the former, will clearly appear to any one beholding them. But this, as we have already hinted, is ſeen without Controverſie in the brains of a Calf, a Sheep, and ſome other four-footed beaſts; where, when the *Nates* are ſignally great, the *Teſtes* grow to the ſame in a very ſmall bulk. Further, that the medullary Proceſſes lead from theſe into the Cerebel, and convey the animal Spirits by this by-path, is ſo manifeſt, that none who hath carefully beheld theſe parts, can be able any further to helitate or be doubtful of it. For indeed the little hairs or fibres wherewith theſe proceſſes, aſcending into the Cerebel, are marked, are otherwiſe figured and placed than thoſe which are beheld in the neighbouring proceſs deſcending from the Cerebel towards the oblong Marrow.

Moreover, either pair of Prominences do not only communicate among themſelves mutually by their ſtretched out wings, but alſo another medullar Proceſs, going croſs-wiſe, knits together the aforeſaid Proceſſes ſtretched out from thence into the Cerebel; and from this joyning together of them two ſmall Nevres are produced, which bending down on either ſide, and being carried forward, enter the *Dura Mater*, and ſo go ſtraight through it, till having reached to the moving Nerves of the Eyes, they go forth of the Skull at the ſame hole with them, going forward, ſtraight to the Throchlear Muſcle of the Eye. Concerning theſe little Nerves it is obſerved, that when many others proceed from the ſides or the Baſis of the oblong Marrow, theſe ariſe from the aforeſaid Prominences in the bunching forth at the top. The reaſon of which, if I be not miſtaken is this: We have affirmed, that theſe Prominences do receive and communicate to the Brain the natural inſtinct delivered from the Heart and Bowels to the Cerebel; and on the other ſide, or back again, do transfer towards the *Præcordia*, by the mediation of the Cerebel, the forces of the Paſſions or Affections received from the Brain; but in either action the motion of the Eyes is affected with a certain manifeſt Sympathy. For if pain, want, or any other ſignal trouble afflicts the *Viſcera* or the *Præcordia*, a dejected and caſt down aſpect of the Eyes will declare the ſenſe of its trouble: when on the contrary, in Joy, or any pleaſant Affection of the *Præcordia* or *Viſcera*, the Eyes are made lively and ſparkle again. In like manner, the Eyes do ſo clearly ſhew the Affections of the Mind, as Sadneſs, Anger, Hatred, Love, and other perturbations, that thoſe who are affected, though they ſhould diſſemble, cannot hide the feeling and intimate conceptions of the mind. Without doubt theſe ſo happen, becauſe the animal Spirits, tending this way and that way in this diverting place between the Brain and the *Præcordia*, do at once ſtrike thoſe Nerves as the ſtrings of a Harp. Wherefore from this kind of conjecture which we have made concerning the uſe of theſe Nerves, we have called them Pathetical, although indeed other Nerves alſo may deſerve this name.

There yet remains for us to take notice of the aforeſaid Prominences, that either of theſe pairs, and the Proceſſes hanging on them, are diſtinguiſhed from the Trunk of the oblong Marrow lying under by the Cavity between them; ſo that this Cavity or *Ventricle* ſeems to exiſt only ſecondarily, becauſe the empty ſpace between the aforeſaid bodies, placed above and beneath, ſeparating the ſame one from another, ought to come between. But this Cavity ſeeming to reſult ſo by accident, hath a very ſignal uſe; for in the middle of its paſſage a ſloping aperture reaches towards the Tunnel, through which the humors ſliding into either of its holes, one made more forward, the other more backward, are ſent out. The more forward hole is placed between the chambers of the Optick Nerves, a little before the Pineal Glandula, into which the ſerous heap being laid up nigh to the confines of the oblong Marrow, ſlides by degrees: but the other hole is opened more backward into the fourth *Ventricle* which is planted under the Cerebel; which hole is covered with a thin Membrane, which girding about its mouth and that of the Cerebel, provides leſt the humors, derived from the fourth Ventricle, or the confines of the Cerebel, ſhould fall down any other way than into that hole; but if at any time that little hole be broken aſunder by a deluge of the Serum, the watry *Latex* ſliding down upon the Baſis of the oblong Marrow, overwhelms the origines of the Nerves, and ſo brings Convulſive diſtempers and meltings, and not ſeldom deadly, of the vital Spirits, as I have obſerved in the bodies of many dying of Cephalick Diſeaſes.

CHAP. XV.

Of the Uſes of the Cerebel, and ſome of its Parts and Proceſſes.

HAving hitherto continued the former Tract of the oblong Marrow, which as it were the Kings High-way, leads from the Brain, as the Metropolis, into many Provinces of the nervous ſtock, by private receſſes and croſs-ways; it follows now that we view the other City of the animal Kingdom. The ſituation of this being remote enough from the former, its kind of ſtructure is alſo different from it: yea it ſeems that there are granted to this, as to a free and municipal City, certain Priviledges and a peculiar Juriſdiction.

The Cerebel is placed a little below the orbicular Prominences in the hinder part of the Head; where growing to the Trunk of the oblong Marrow by a double little foot, it appears almoſt of a Spherical figure. Its ſuperior gibboſity coheres towards the ſuperficies to the border of the Brain by the intervention of the *Pia Mater*; but nevertheleſs it is intimately united to it, nor is there any immediate commerce between this or that or their parts. There hath been ſpoken enough already of the figure and ſituation of the Cerebel, and of its various Proceſſes, and how it is faſtned to the oblong Marrow; it now remains that we proceed to deſign or draw out the offices and uſes of it, and its ſeveral parts. Where in the firſt place ſhall be inquired into, what kind of office the Cerebel is endued with in the animal œconomy; then when we ſhall deſcend to particulars, there are more things worthy to be noted, which will offer themſelves

ſelves to our conſideration: *viz.* firſt the infoldings of the Veſſels covering the whole compaſs of the Cerebel, and eſpecially its hinder part, with the heap of Kernels: ſecondly, its folds and lappets ordained with a certain and determinate ſeries, and almoſt after a like manner in all: thirdly, the double ſubſtance of the folds, *viz.* cortical and marrowy: and the concentring of all the medullary tracts in two large Marrows or middeſts: fourthly, either little foot or pedeſtal of the Cerebel made out of thoſe two middle *Marrows*: and in either pedeſtal three diſtinct medullar Proceſſes to be found: fifthly, the annular Protuberance made by a proceſs of the Cerebel deſcending into the medullar Trunk: ſixthly, ſome Nerves, which ariſing immediately from this Protuberance and other Nerves in the neighbourhood, which being deſigned for the involuntary Function, receive the influences of the animal Spirits from the Cerebel: Laſtly, the Ventricle or Cavity lying under the Cerebel ought to be conſidered.

1. As to the office or uſe of the Cerebel in general: nothing of it occurs, ſpoken by the Ancients, worthy its fabrick, or agreeable to its ſtructure. Some affirm this to be another Brain, and to perform the ſame actions with it: but if any one ſhould have a ſoft and fooliſh Brain, I greatly doubt, if he ſhould become wiſe, though he ſhould obtain perhaps a more hard and ſolid Cerebel. Others place the Memory in this part, ſuppoſing the Cerebel to be as it were a Cheſt or Box, wherein the Idea's or Images of things, before laid up, are kept apart from the incourſe of freſh Species. But it is far more probable, that this faculty reſides in the *cortical* Spires of the Brain, as we have elſewhere ſhewn. For as often as we endeavour to remember objects long ſince paſt, we rub the Temples and the fore-part of the Head, we erect the Brain, and ſtir up or awaken the Spirits dwelling in that place, as if endeavouring to find out ſomething lurking there; in the mean time, there is perceived nothing of endeavour or ſtriving motion in the hinder part of of the Head. Beſides, we have ſhewn, that the Phantaſie and Imagination are performed in the Brain; but the Memory depends ſo upon the Imagination, that it ſeems to be only a reflected or inverſe act of this: wherefore that it ſhould be placed with it in the ſame Cloiſter, to wit, in the Brain, is but neceſſary; for it plainly appears, that there is no immediate commerce between the Brain and the Cerebel.

When ſome time paſt I diligently and ſeriouſly meditated on the office of the Cerebel, and revolved in my mind ſeveral things concerning it, at length, from the Analogy and frequent Ratiocination, this (as I think) true and genuine uſe of it occurred; to wit, that the Cerebel is a peculiar Fountain of Animal ſpirits deſigned for ſome works, and wholly diſtinct from the Brain. Within the Brain, Imagination, Memory, Diſcourſe, and other more ſuperior Acts of the animal Function are performed; beſides, the animal Spirits flow alſo from it into the nervous ſtock, by which all the ſpontaneous motions, to wit, of which we are knowing and will, are performed. But the office of the Cerebel ſeems to be for the animal Spirits to ſupply ſome Nerves; by which involuntary actions (ſuch as are the beating of the Heart, eaſie Reſpiration, the Concoction of the Aliment, the protruſion of the Chyle, and many others) which are made after a conſtant manner unknown to us, or whether we will or no, are performed. As often as we go about voluntary motion, we ſeem as it were to perceive within us the Spirits reſiding within the fore-part of the Head to be ſtirred up to action, or an influx. But the Spirits inhabiting the Cerebel perform unperceivedly and ſilently their works of Nature without our knowledge or care. Wherefore whilſt the Brain is garniſhed as it were with uncertain Meanders and cranklings turnings and windings about, the compaſs of this is furniſhed with folds and lappets diſpoſed in an orderly ſeries; in the ſpaces of which, as in deſigned Orbs and Tracts, the Animal Spirits are expanded according to the Rule and Method naturally impreſſed on them. For indeed thoſe in the Cerebel, as it were in a certain artificial Machine or Clock, ſeem orderly diſpoſed after that manner within certain little places and boundaries, that they may flow out orderly of their own accord one ſeries after another without any driver, which may govern or moderate their motions. Wherefore foraſmuch as ſome Nerves perform ſome kind of motions according to the inſtincts and wants of Nature, without conſulting the government of the will or appetite within the Brain, why may it not be imagined, that the influence of the Spirits is derived wholly from the Cerebel for the performing of theſe? For it ſeems inconvenient, that for theſe offices which ſhould be performed without any tumult or perturbation, the Spirits ſhould be called out of the Brain, which are continually driven into fluctuations as it were with the winds of Paſſions and Cogitations.

As I only imagined of the uſe of the Cerebel after this manner, I was led to it at length by a certain thread of Ratiocination; to which afterwards happened an Anatomical inſpection, which plainly confirmed me in this Opinion. For in the frequent Diſſection of the Heads of ſeveral ſorts of Animals certain Obſervations did occur, which ſeemed to put this matter out of all doubt. For I firſt obſerved, the pairs of Nerves, which did ſerve to the Functions, wont to be performed by the Inſtinct of Nature, or the force of the Paſſions, rather than by the beck of the will, ſo immediately to depend on the *Cerebel*, that from thence only the influence of the Animal Spirits ſeems to be derived into their origines or beginnings. By what means the Nerves ariſing from the *Cerebel*, or receiving from it the proviſion of the animal Spirits, do perform only involuntary actions, ſhall be declared hereafter; in the mean time, for the confirmation of this Opinion, we have in readineſs another Reaſon of no leſs moment.

Therefore

Therefore ſecondly, we took notice, that not only the conformation or make of the Cerebel was ordained after a certain and peculiar manner, that is, that its frame or bulk was couched together with folds or little circles, diſpoſed in a certain diſtinct ſeries, and apt method, and proportionate within themſelves, as hath been ſaid; whence it may be argued, that the Spirits ariſing from hence, and flowing outwardly, are imployed or beſtowed on ſome certain works determinate to one thing. But further it is obſerved, that in all Animals, although they differ in form and kind, yet the figure of the Cerebel is always very like or wholly the ſame. The Brain and oblong Marrow are figured in many after a divers manner; for as we have ſhewed before, there is ſome difference of theſe parts found in man and four-footed beaſts; but between either of theſe, and Fowls and Fiſhes, there is a notable difference as to theſe parts. Notwithſtanding in all theſe the Cerebel, furniſhed wholly with the ſame lappets or little circles alike infolded one in another, is marked with the ſame form and proportion; which certainly is a ſign that the animal Spirits in this work-houſe are begotten and diſpenſed, as it were by a certain dimenſion, for certain neceſſary offices, which are performed in all after the ſame manner; and which cannot be any other than the motions and actions of the *Viſcera* and *Præcordia*. As to the other Faculties, of which ſort are Imagination, Memory, Appetite, yea local motions and ſenſe are exerciſed after one manner in thoſe living Creatures, and after another manner in others; wherefore their brains are formed after a divers manner. But the motions of the Heart and Reſpiration in all endued with an hot blood, are performed after a like manner, that is, with a perpetual viciſſitude of *Syſtoles* and *Diaſtoles*. Beſides, another office is to be aſſigned to the Cerebel, and different from what is convenient or agreeable to the Brain; becauſe where the folds and turnings are wanting in the Brain, they are conſtantly found in the Cerebel. Beſides theſe reaſons drawn from Anatomy, the Pathology of the humane Body affords many others, which confirm the aforeſaid office of the Cerebel. For it oftentimes happens that cruel and horrid Symptoms infeſt the *Præcordia* and the region of the middle or loweſt Belly; whilſt in the mean time, the morbifick cauſe lyes in the Cerebel, or nigh its confines. I have known ſometimes men labouring only in appearance with a Dyſcraſie of the hinder part of the Head, who complained of frequent Swooning and repeated meltings of the Spirits or Deliquiums, as if they were juſt dying: in whom notwithſtanding nothing more could be detected of the morbifick cauſe or its ſeat, but that the Patient perceived a great heavineſs and pain in the hinder part of the Head, and that upon any ſudden motion or bending back of the Head, they were ready to dye. In truth, the Symptoms which are wont to be raiſed up in the diſtemper called the *Incubus* or Night-mare, *viz.* loſs of ſpeech, and a mighty weight or load that ſeems to lye upon the breaſt, proceed altogether from the morbifick matter fixed in the confines of the Cerebel, and obſtructing the paſſages of the Spirits deſtinated for the *Præcordia*. But indeed this Hypotheſis of the office of the Cerebel ſhall be more illuſtrated and confirmed from the uſes of its ſeveral parts, being rightly deſigned or drawn forth.

As to the parts and accidents of the Cerebel, 1. we take notice, that the infoldings of the Veſſels every where cloath the Cerebel no leſs than the Brain, alſo that the ridges and furrows of its folds intimately hide or cover it, which certainly is a ſign that the animal Spirits are begotten in this other work-houſe of them from the watering blood, and inſtilled into its ſubſtance: which thing alſo more clearly appears, becauſe the Arteries and Veins are not only variouſly complicated in the ſuperficies of the Cerebel, but both of them in like manner as in the Brain, ſend forth frequent ſhoots into its more inward ſubſtance; wherefore whilſt the moſt ſubtil and ſpirituous part of the blood being carried through long windings about, and as it were ſerpentine chanels of the Veſſels, and ſo ſublimed into Spirits is received within; the bloody part is carried away by the ſhoots of the Veins ſent alſo deeply down. Further, even as the more watry portion of the blood, deſtinated for the Brain, runs into the *Choroeidal* infolding; (whereby it may there lay aſide its unprofitable Phlegm into the Glandula's) ſo for the ſake of ſeparating the Phlegm an heap of Glandula's, with the foldings of the Veſſels, as it were a Receptacle fitted for this buſineſs, is placed in the hinder Region of the Cerebel.

2. From the blood, after this manner cleared from Phlegm, and made ſubtil by a long circulation, very pure and ſpirituous liquor is inſtilled into the cortical ſubſtance of the Cerebel, which is preſently exalted by the Ferment there placed into animal Spirits. For indeed we have affirmed, that the Spirits are procreated only in the cortical part of the Cerebel, as in that of the Brain: wherefore, becauſe this kind of Cortex is wanting to the oblong and ſpinal Marrow, we think theſe parts do ſerve only for the exerciſe of the animal Spirits, and not for their production.

3. The Spirits every where produced within the cortical or exterior compaſs of the Cerebel, in which they are preſently prepared for the work of the animal Function, are derived from all the folds into the medullar tract, and thence into two ample middle Marrows; where they keep full as it were the fountain or ſpring, and there like the bubling up of waters, are circulated within with a perpetual turning and from thence they continually ſtream forth into the parts of the nervous Syſtem proper to themſelves.

4. As to the ways of Emanation it is obſerved, that the two middle Marrows of the Cerebel paſs as it were into two pedeſtals or little feet, by which they are faſtned to the trunk of the oblong Marrow; and for that in either lilttle foot of it three diſtinct medullar Proceſſes are found, all theſe, or at leaſt two of them, are as it were ſo many paths whereby the animal Spirits ſtream forth from their fountain and flow back a gain.

5. The

5. The firſt of theſe Proceſſes aſcends into the Cerebel from the orbicular Prominences, the uſe of this we have already declared; to wit, that there may be a certain paſſage between theſe Prominences and the Cerebel, in which, whilſt the animal Spirits, as in a by-path, move this way and that way, to and fro, they may tranſmit both the force of the Paſſions from the Brain by the interpoſition of the Cerebel to the *Præcordia*, and convey alſo the natural Inſtincts delivered to the Cerebel from the *Præcordia* and *Viſcera* towards the Brain. But the ſecond Proceſs deſcending ſtraight from the Cerebel, embraces the medullar Trunk, and ſo going round about it, conſtitutes the annular or ringy Protuberance, out of which the fifth, ſixth and ſeventh pair of Nerves take their originals; ſo indeed, that this Protuberance ſeems to be the Ware-houſe or Store-houſe of the Spirits flowing from the Cerebel, from which they may influence and be derived into the oppoſite paſſages of the Nerves. Laſtly, the third proceſs of either little foot, deſcending from the Cerebel into the oblong Marrow, is inſerted into its Trunk over againſt where the eighth pair of Nerves have their Original: ſo that it ſhould ſeem very likely, the proviſion of the Spirits deſtinated for this Nerve is derived alſo by this way from the Cerebel; then what Spirits ſuperabound, remaining longer than this Nerve requires, they ſliding down into the common belly or chanel of the oblong and ſpinal Marrow, increaſe the plenty of thoſe parts. For this ſame end the ſmooth and pyramidal bodies are reached out of the annular Protuberance above the oblong Marrow towards the Spine, to wit, that by the paſſage of thoſe Proceſſes the Spirits of that proviſion or ſtock ſuperabounding, might flow out partly into the beginning of the eighth pair, and partly into the common tract of the medullar Trunk.

Thus much we have ſpoken briefly and ſummarily of the Uſes of the Cerebel, and of its parts and Proceſſes. But that it may be the better underſtood, and alſo that this new thought of Theory concerning the involuntary Function of the animal Regiment, may be more clearly illuſtrated, we ſhall here give you a more particular Order or Method of the Spirits brought forth in the Cerebel, and as it were take a view of, or muſter their Arms or Forces. Further, it will ſeem to the purpoſe, that we ſhould deſign or draw forth more openly the abundance or plenty of the Nerves receiving their gifts from this Fountain of the Spirits concerning the Acts to be performed only of the involuntary Function.

CHAP. XVI.

Of the various Order and diverſe manner of Exerciſe of the Spirits produced in the Cerebel for the Acts of the involuntary Function.

After having ſhewn, that the office of the Cerebel is to procreate animal Spirits apart from the Spirits begotten in the Brain, and to diſpenſe them into the Nerves, the Executors of the involuntary Actions and Paſſions; there yet remains to be unfolded by what manner of œconomy or government the Spirits inhabiting the Cerebel and made free, are buſied both by an inteſtine Circulation, within their proper dwelling places, and are wont to be expanded and flow out with an exterior irradiation for the neceſſities and wants of other parts: then theſe things being ſhewn, we ſhall deſign more particularly the Uſes and Offices of the Nerves, and of ſome other Proceſſes doing ſervice to this Government.

As to the firſt, as the Cerebel is the other primary Root of the ſenſitive Soul, or the Fountain from whence the animal Spirits, being diffuſed through the whole ſubſtance of it and its Appendix, are continued ſtill under the ſame ſyſtaſis and radiant Contexture, it is to be noted, that this radiation of the Spirits from the Cerebel doth flow after another manner than the other from the Brain: becauſe this being left to it ſelf, is beſtowed by a conſtant efflux or flowing out on the Organs both of the vital Function and the merely natural, and its expences by an equal continual proviſion of Spirits, are made up again from the bloody maſs continually inſtilled in. But on the contrary, the Spirits flow out from the Brain, neither by ſuch a continual courſe without intermiſſion and by little and little, nor are ſuſtained by a perpetual proviſion and ſliding in by degrees; but both the loſs of them, and their refection, are uncertain, unequal, and variouſly interrupted. For neither are the ſpotaneous Acts of the Function it ſelf, to which they ſerve, performed after any conſtant or always the ſame manner; but according to exterior accidents and occaſions we put them forth by heaps, and with a certain force ſometimes, and again ſometimes we ſuffer them to be wholly intermitted and unimployed. Therefore the Spirits alſo are in like manner ſupplied with an uncertain meaſure; to wit, they are inſtilled in ſleep plentifully and more copiouſly, but waking more ſparingly and with hard labour, or ſcarce not at all. Yea the involuntary portion it ſelf of the ſenſitive ſoul (which flows from the *Cerebel*) for that it hath a near commerce and affinity (as was already ſaid) with the other radicated in the Brain, therefore it is wont to be much diſturbed in the performing

its

its office equally and peaceably, and being variouſly affected and agitated by the impulſes ſent here and there, or from this place and that, it is compelled, ſometimes to contract, ſometimes to extend its *Syſtaſis* in the whole or in part, and ſo is rendred obnoxious to ſeveral Paſſions, and ordinarily inſtigated to the performing irregular and diſorderly actions.

But indeed the contexture of the Spirits, or the part of the Soul irradiating the Cerebel and its Appendix, is both affected with a certain ſenſe, and is urged into motions appropriate to it ſelf, though divers. The ſenſe or Sympathy belonging to this, if it be terminated within the confines of the Cerebel, is always private, nor goes any farther forward to the Brain with a more ſtrong undulation or wavering; and becauſe it is performed the living Creature knowing nothing of it, unleſs by the effect it cannot be known, for that it excites a peculiar motion. But ſuch an affection of the Cerebel is implanted in it, that by every new diſpoſition of the *Præcordia* and *Viſcera* communicated to this from beneath, alſo from every violent paſſion excited within the *Forum* of the Brain, and ſo ſent from above, a certain impreſſion is carried to the inhabitants of the Cerebel: by which indeed they are diſpoſed into various ordinations for the performing theſe or thoſe motions reſpectively.

For examples ſake, ſo long as the tranquil region of the Cerebel, like a ſerene and fair Heaven, is free from all perturbation, the Spirits its inhabitants, being poured out with a pleaſing ſenſe, or as it were a certain complacency, flow within their proper habitations, both with a gentle circulation, and alſo with an equal flowing out enter the beginnings of the Nerves ſerving to the Functions both vital and natural: by which indeed eaſie Reſpiration, the Pulſe, Chylification, and other offices of the ſame nature, are performed peaceably. But if that any trouble or moleſtation happen outwardly to any one, from whence an impreſſion of it is communicated to the Cerebel, preſently a troubleſome ſenſe being ſtirred up there, it diſturbs the animal Spirits in the Fountain it ſelf, and ſo is wont to excite irregular motions in the Organs of the involuntary Function. For from hence the frequent alteration of the Pulſe and of Reſpiration, alſo Cramps of the *Viſcera*, and convulſive motions ariſe unknown to us, or alſo againſt our wills. But an impreſſion ſent from elſewhere to the Cerebel, and inducing the ſame kind of a troubleſome ſenſe, either aſcends by the paſſage of the Nerves from the *Præcordia* and *Viſcera*, or it is carried from above from the Brain by the paſſage of the orbicular Prominences; as ſhall be ſhewn more largely anon.

In the mean time, from theſe things already ſhewed of the paſſive power or ſenſe of the Cerebel, it may be eaſily collected, by what means, with what order and ſeries the animal Spirits, ariſing from the ſame, are moved. But firſt you muſt diſtinguiſh between their twofold motion. For one is cuſtomary and ordinary, conſiſting in a perpetual and equal efflux of Spirits; by which indeed, they flowing into the beginnings of the Nerves nigh their riſings, eſpecially of the intercoſtal and wandring pair, the ſolemn acts of the Pulſe, Reſpiration, Chylification, and others of the involuntary Function are performed. Then ſecondly, the other motion happens extraordinary and occaſional, which the ſame Spirits perform confuſedly, as it were in diſturbed orders: as when the Pulſe becomes quicker or ſlower than it ought, or the Reſpiration unequal or interrupted; and when the other Faculties, which belong to this Claſs, are perverted from their regular and conſtant manner. But theſe kind of extraordinary motions are again twofold, to wit, for that its inſtigation proceeds from a double bound; for the impulſe whereby the Spirits inhabiting the Cerebel, are compelled into an irregular action, (as we have but now intimated) is carried either from beneath, *viz.* from the *Præcordia* and *Viſcera*; or it is wont to be tranſmitted from above, to wit, from the Brain.

As to the firſt, if at any time the *Præcordia* grow too hot, and are burnt with a feveriſh heat, preſently by the paſſage of the Intercoſtals and the wandring pair of Nerves, the Spirits reſiding in the Cerebel, being warned of this evil, inſtitute more frequent and ſtronger acts both of the Pulſe and of Reſpiration. In like manner, if by chance the humors and ſharp Juyces irritate or greatly trouble or afflict the Coats of the Ventricles or Inteſtines through the ſenſe of this affection communicated to the Cerebel, the inſtinct of performing the motion is reciprocated, whereby the fibres of the parts, being contracted and wrinkled together, endeavour the ſhaking off of the hurtful matter. More inſtances might be here brought of all the other acts of the vital or merely natural Function, of which beſides it may be obſerved, that when a ſenſe of the trouble is immediately conveyed from the *Præcordia* or *Viſcera* to the Cerebel, this affection, like the waving of waters, is either ſtopt or terminated there, from whence a motion, as the buſineſs requires, unknown to the Brain, is preſently retorted, as when the actions of the *Præcordia* are altered by a feveriſh diſtemper without our knowledge; or ſecondly, that ſenſe of the trouble being tranſmitted to the Cerebel, for that it is more vehement, it unfolds it ſelf more largely, and like a ſtrong waving of waters, paſſing through the Cerebel, goes forward further even to the Brain, and warns its inhabitants of the evil; by which they being incited to oppoſe the enemy, cauſe a motion of another kind: So (as hath been ſaid) when the *Præcordia* grow cruelly hot, the Cerebel feeling this, makes the Pulſe and Reſpiration ſtronger. But further, the Brain being warned of the ſame trouble, ſeeks and diligently requires cold drink and other remedies to moderate the heat. Moreover, it is after this manner alſo in ſeveral other actions, which though they are regular, yet being made in the Brain without any previous knowledge, they are ſaid to be done by Inſtincts merely natural; as when brute Animals, being newly brought forth, preſently ſeek for the Dams Teats, and greedily ſuck; or Birds, without any ſhewing or Example, build Neſts with wonderful Art, lay eggs, and hatch young ones. In theſe kind of works the Brain being taught

taught before by none: directs fit means to the ends instituted by Nature: which indeed seems to be done by this means. The sense of every necessity being brought to the Cerebel, incites the Spirits inhabiting it to succour it; which when they are not able to do, the impression going from thence further forward, is carried to the orbicular Prominences: by which the Spirits there inhabiting, being presently struck, form the Appetite or the intention of performing, which being thence communicated to the Brain, it readily causes that local motions, fit for the executing of the work, be retorted. Of these we shall speak anon a little more largly, when we treat of the respect which happens between the orbicular prominences and the annular Protuberance.

In the mean time, we shall take notice in the second place, that the irregular motions of the Spirits inhabiting the Cerebel, are wont also, by reason of the force of the affections, to be transmitted from thence to the Brain: for as often as a violent passion, as Joy, Sadness, Anger, Fear, or of any other kind, is conceived in the Brain, presently the impression of the same being brought through the by paths of the Prominences into the Cerebel, disturbs the Spirits destinated to the vital or merely natural Function in their very fountain, and for that reason presently induces notable mutations in the Organs of those Functions.

What hath been spoken hitherto of the Cerebel being imployed about the offices of the involuntary Function only, also concerning the sense and the motions both usual and irregular of the Spirits inhabiting it, will be made more clear, if lastly we shall shew the offices of the Nerves and of the other processes, immediately depending upon the Cerebel, to be no other than such as perform only involuntary Acts: which shall be briefly and succinctly done, as far as is pertinent to our purpose, because a more full consideration of them is left to another place.

CHAP. XVII.

Of the Nerves, which receiving the flores or companies of the Spirits from the Cerebel, bestow them on the Acts of the involuntary Function.

WE have already shewed, that out of the annular Protuberance (which is a certain Process of the Cerebel) three pairs of Nerves, to wit, the fifth, sixth, and seventh immediately arise. We have said that Protuberance to be as it were a Repository or Store-house, wherein the Spirits flowing out of the Cerebel, and to be derived into the depending Nerves, as occasion serves, are kept: and in the mean time, whilst they remain there, they who stream out from either middle Marrow of the Cerebel divisively, meeting mutually in this Cirque, are united together. But as the aforesaid three pairs of Nerves receive the forces of the Spirits from the Cerebel by the mediation of that Protuberance; so also the eighth pair having its rise near the insertion of the other (*viz.* the lowest) medullar Process sent down from the Brain, seems to derive by its passage the influence of the Spirits no less from the Cerebel: wherefore when these four conjugations of Nerves owe the Tribute of their Spirits wholly to the Cerebel, if I shall shew that all these Nerves serve chiefly and almost only to the involuntary acts of the Senses and Motions, surely this will be a signal Argument, that according to our Hypothesis, the office of the Cerebel is to beget and to dispense the animal Spirits requisite for the involuntary Functions.

Therefore in the first place we observe of the fifth and sixth conjugation of Nerves, that as this arises out of the Basis of the greater Ring, and that from its sides both in man and in four-footed beasts; the fifth pair being carried more forward, distributes its branches into the Glandula's of the Eyes, into the Nostrils, into the Palate, Teeth, yea and into most parts of the Face and Mouth; but the sixth pair is wholly bestowed on some Muscles of the Eyes. Further, out of the trunk of the fifth pair two shoots, and another out of the Nerve of the sixth pair bending back behind, meet together; and what is wonderful, and not before taken notice of by Anatomists, the intercostal Nerves, destinated to the *Precordia* and *Viscera*, do make a Trunk; so that the Nerves, of the fifth and sixth pair stretch out a double Ramification, to wit, one more above about the parts of the Mouth and Face, and the other lower through the *Viscera* of the middle and lowest Belly. But it will appear clearly to any one considering this thing more carefully, that the chief branches of either partition are imployed about the involuntary offices of Motion and Sense, of which sort those are chiefly, that either cause the passions, or perform the natural Instincts.

1. Concerning the intercostal Nerve, which (as was said) being radicated in the Nerves of the fifth and sixth pair, depends as to its origine wholly on the Cerebel, it is not here to be doubted but that it looking towards the *Precordia* and *Viscera* in a man, and towards these latter only in most four-footed beasts, is bestowed on the Functions only vital and merely natural, and so confers little or no-

thing to ſpontaneous Actions. Further, foraſmuch as this Nerve reaching forth into *Præcordia* and *Viſcera* of the whole Abdomen, is continued by its ſuperior ramification alſo into the Eyes, as alſo into the parts of the Mouth and Face; certainly from hence a true and genuine reaſon may be given wherefore in every paſſion the Eyes, Face, and Mouth do ſo correſpond with the affections of the *Præcordia*, often unknown to us or againſt our minds, that oftentimes we are compelled to betray the moſt intimate ſenſe of the Heart by the continuance and aſpect. Yea, hence a reaſon may be brought, why in ſneeſing, yawning, laughing, and crying the Muſcles of the Face conſpire ſo in motion with the *Præcordia*. Beſides, when in man different from any other living Creatures beſides, as we ſhall ſhew afterwards, many ſhoots are ſent from the intercoſtal Nerve to the Nerve of the Diaphramga; this certainly is the cauſe why riſibility is the proper affection of man.

But the Trunk of the fifth pair being carried more forward, and diſtributing its branchings through the parts of the whole Face, cauſes the ſame not only to be pathetically moved, and figured according to the affections of the *Præcordia*; but alſo produces ſome acts, both of motion and ſenſation, of another kind, which for the moſt part are involuntary, and ſo ſeem to depend wholly upon the Cerebel immediately. For example, this Nerve imparts ſhoots to either mandible requiſite for the buſineſs of chewing: but it is very well known, that the taking in of the food at the mouth is the firſt and oldeſt buſineſs of every Animal, which indeed is taught by natural Inſtinct before any knowledge of the Brain. But as to the Senſes, the branches of this pair conduce ſomething to the ſmelling, but for the moſt part for the knowing and chuſing of ſavors. Hence it comes to paſs, that as odors refreſh the Brain by the ſmelling Nerves, ſo alſo they affect the Cerebel by the branch of this pair, and are wont by that means to recreate the *Viſcera* and *Præcordia*. But ſapors or taſtes (for that they are almoſt the peculiar Province of this) carry whatſoever they have of pleaſantneſs or trouble, firſt to the Spirits inhabiting the Cerebel, and then by their conſent to the *Præcordia* and *Viſcera*. Hence it is, that a Pectoral not only allays hunger, but the very firſt taſting of Wine raiſes up thoſe that are fainting or ſwooning away. Moreover, foraſmuch as from this Nerve certain branches ſerve for the taſte, and others for the ſmell, there is contracted ſo ſtrict an affinity between either of theſe Senſories, that nothing pleaſes the taſte unleſs it be approved of by the ſmell: and the loſs of one of theſe ſenſes oftentimes cauſes the privation or the diminution of the other.

2. Concerning the Nerve of the ſixth conjugation we obſerve, that as one ſhoot is bent back for a root of the intercoſtal Nerve, the remaining Trunk of it being carried forward towards the ball of the Eye, is diſtributed to two of its Muſcles, *viz.* to the ſeventh, proper to beaſts, and to the drawing Muſcle. Hence may be inferred, that this Nerve, beſides the influence of it beſtowed on the vital and natural Function, ſerves alſo for the producing ſome pathetick motions of the Eye, to wit, ſuch as are wont to obey the affections of the *Præcordia* and *Viſcera*; ſo that the whole proviſion of the animal Spirit, which it receives from the Cerebel, it beſtowes only on involuntary acts.

3. The ſeventh pair, or the hearing Nerves, ſeem alſo to depend upon the Cerebel, for aſmuch as they take their originals out of the annular Protuberance: but the uſe of them is a little otherwiſe in man than in four-footed beaſts. For in him the annular Protuberance is one, and that very big, from whoſe lower margin the auditory Nerves proceed: but in Brutes the Protuberance is twofold, *viz.* one greater, ſent down from the Cerebel, in which the beginnings of the fifth and ſixth pair of Nerves conſiſt; then near this there is another leſſer, and as it were ſecondary, from which the auditory Nerves proceed. This leſſer and lower Ring doth not ſo manifeſtly depend on the Cerebel, as the former; but there is ſtretched out from either height of it a white medullar line upon the oblong Marrow in the bottom of the fourth Ventricle: ſo as this ſeems to receive either the Spirits from the oblong Marrow, or at leaſt to carry into the ſame the ſenſible Species: for what uſe it is ſo conſtituted ſhall be inquired into afterwards; for concerning theſe Nerves of the ſeventh pair, foraſmuch as ſome offices of them very much illuſtrate the goverment or œconomy of the Cerebel, we ſhall diſcourſe here a little more largely.

Therefore in man, who hath got a great and undivided annular Protuberance, and auditory Nerves coming out of its margin or brim, ſhews its ſtock received of the Cerebel: by which means we may ſee the tasks of thoſe Nerves quadrate with the aſſigned government of this. We have ſhewn before the Proceſſes (which in a manner may be called diſtinct Nerves) of the ſeventh pair to be twofold on either ſide: one, the ſofter of theſe, ſerves only for the ſenſe, but the other harder ſeems to perform ſome motions. This latter Nerve, being carried without the Skull, is divided into three branches, all which ſerve to pathetick motions, or at leaſt to ſuch as are performed without conſulting the Brain.

1. The firſt of them being bent back towards the auditory paſſage, is beſtowed on the Muſcles of the Ear. Without doubt, by the action of this, it is effected, that all Animals at the ſudden impulſe of a ſound or noiſe, erect their Ears as it were to catch the ſound too ſoon paſſing by. 2. The other branch of this ſame Nerve climbing over the Muſcles of the Jaw, ſends forth ſhoots towards either corner of the Eye: which are inſerted into the muſcles lifting up the Eye-lids; the office of which is certainly to open ſuddenly the Eyes at the ſudden approach of any ſound, and as it were to call them forth to watch, that by the ſtroke of the Air being brought to the Ear, the Eye might preſently look about to ſee what is the matter, and whether there might be any danger near or not: which alſo all creatures do unthought of. 3. The third branch of the ſame auditory Nerve deſcending towards the root of the Tongue, is diſtributed to its Muſcles, and to thoſe of the Bone *Hyoides*, and ſo actuates ſome of the Organs for the framing

the

the Voice. For this reaſon in ſome meaſure it comes to paſs, that living Creatures being aſtoniſhed at an unaccoſtomed or horrid ſound, preſently putting forth an uncertain voice, cry out and make a noiſe. But the conformation of theſe kind of Nerves in man ſerves for another more noted uſe, to wit, that the voice might fitly anſwer to the hearing, and that this might be ſet as the Echo of the ſound admitted by this: ſo indeed, as on the other ſide, there be two Nerves of the ſame pair, the ſound is received by the hearing, through one, which is rendred again by the voice through the other. The common and extrinſick Echo conſiſts in this, that a certain undulation or waving of the Air ſhaken or moved, being ſtirred up, and tending towards or about, when by reaſon of ſome ſtop or hinderance, it cannot go any further directly, being preſently repercuſſed or ſtruck back or reflected at certain angles, it is terminated contrary to the former bound. In like manner, in the hearing, the impreſſion of the ſound, or the Species admitted to the Ears by the hearing faculty of the Proceſſes of the ſame or neighbouring Nerve, and being carried inwardly towards the Cerebel and common Senſory, and from thence again reflected on the vocal proceſs, it is carried out by the Mouth. But between theſe there is ſome difference, to wit, foraſmuch as the outward Echo renders back the ſound immediately; but the ſound of the Hearing is not neceſſarily carried forth at the mouth preſently, but that this leaves an Idea in the Head, according to which afterwards, as occaſion ſerves, the voice is formed, which bears the type and image of that, though ſome time before admitted.

But here (if I may digreſs a little) we ſhould inquire in what part of the Head the Ideas of ſounds are left: whether only in the Brain, which is the Cheſt of Memory accquired as it were artificial, or whether not alſo in the Cerebel, which is the place of natural memory? Truly we ſuppoſe, that ſounds belong to both theſe, as it were to diſtinct Store-houſes. Every audible impulſe being ſtruck againſt the Ear, it is preſently carried by the paſſage of the auditory Proceſs to the annulary Protuberance; but from thence it is carried, as other ſenſible Species, to the chamfered bodies or the common Senſory; (which way it paſſes thither, ſhall be ſhewed afterwards) this impreſſion tending from thence farther, and being alſo delivered to the Brain, ſtirs up the Imagination, and ſo leaves in its Cortex an image or private mark of it ſelf for the Memory. Further alſo, as the auditory Proceſs depends on the Cerebel, and receives from it the proviſion of the animal Spirits: ſo it is moſt likely, that by the receſs of the ſame Spirits the Ideas of the Sounds are conveyed alſo to the Cerebel; which forming there footſteps or tracts, impreſs a remembrance of themſelves, from whence when afterwards the Species there laid up are drawn forth by the help of the vocal proceſs, voices, like the ſounds before admitted, and breaking forth in a certain ordained ſeries, come to be made.

Hence it is uſual, that muſick or melody is ſoon learnt by ſome men, which afterwards they bring forth with exact Symphony, without any meditation or labour of the Brain; to wit, from the diſtinct accents of the heard harmony, the Spirits moving within the Cerebel are diſpoſed into peculiar Schemes; according to which, when they flow on both ſides into the vocal proceſs of the auditory Nerve, they render as it were with a certain ſpontaneous voice, and like a Machine or Clock with the ſucceſſion of Species, the meaſures or Tunes of the Inſtrument which they had drunk in at the ears. Without doubt hence the reaſon may be fought, why ſome men learn Muſick without any trouble, and others hardly or not at all. For it is obſerved, that ſome Children, before they can ſpeak diſtinctly, quickly ſing, and remember certain Tunes; whilſt others, though very ingenious men and of excellent memory, are very Fools at Muſick, and become uncapable, as an Aſs for the Harp; wherefore 'tis commonly ſaid, that ſome have muſical ears, and others are wholly deſtitute of that faculty. In the mean time, 'tis to be confeſſed, that in theſe the Organs of the Voice are not defective; but all the fault, though wrongfully, is caſt on the hearing.

But in truth the genuine cauſe of this defect ſeems to conſiſt in this, that when in all, the audible Species go to the Cerebel ſooner and more immediately than the Brain; yet in ſome the Cerebel being harder, and not eaſily yielding to the received impreſſions, thoſe Species, becauſe they could impreſs nothing of themſelves in their paſſing to the Cerebel, being carried towards the common Senſory, leave their Types or Ideas cheifly and almoſt wholly in the Brain: which part being ſtill buſied with diſturbed motions, is leſs apt to keep diſtinctly the compoſures of Harmony. But in the mean time, in others the Species of audible things, beſides that they are carried to the common Senſory and to the Brain, do alſo affect the Cerebel, eſpecially if they are harmonically figured (foraſmuch as in them there is a ſofter capacity of the impreſſions) with a peculiar order and Scheme of the animal Spirits: where, as the Species of the Harmony being diſpoſed in convenient little places and cells are kept, afterwards they flow out from thence, almoſt unthought of, without any endeavour or labour of remembrance, but in a diſtinct ſeries, and as it were in compoſed modes and figures, and ſo by blowing up the vocal proceſſes, they conſtitute ſweet Tunes and vocal Muſick.

If that the divers ways of paſſage are inquired into, to wit, whereby the audible Species, being carried into the annular Protuberance, do get both to the Brain and Cerebel; I ſay it is not improbable, but out of that Protuberance both a paſſage lyes open into the underlying tract of the oblong Marrow, and as it were the high road; as alſo another paſſage is opened into the Cerebel through the medullar proceſſes of the ſame Ring. But leſt there ſhould perchance be a confuſion of the animal Spirits and the ſenſible Species, (which indeed can hardly be avoided) if the way made for their paſſage ſhould lye open into various paſſages and manifold apertures; therefore concerning this it may well be ſuppoſed, that the Ideas of the Sounds paſs through the Cerebel, when they are carried to the common Senſory; which region being firſt

paſt, they are at length brought by a by-path, *viz.* through the orbicular Prominences to the chamfered Bodies: which perhaps is partly the reaſon, that in the Hearing the perception of the ſenſe ſucceeds ſo late, and the impulſe of the object, in reſpect of ſight, follows ſo ſlowly.

Whilſt therefore the audible Species paſſes through the Cerebel, in ſome men, it leaves in this region (for that it is of a ſoft temper, and fit for the receiving impreſſions) and tracts and marks of it ſelf, and ſo they obtain muſical ears. But in others who have a harder frame of the Cerebel, they produce no tracts of the ſame Sounds, and therefore ſuch are wholly diſtitute of the faculty of Muſick.

As therefore we ſuppoſe the audible Species to paſs through the Cerebel after this manner, a reaſon may be given from hence, wherefore Muſick does not only affect the Phantaſie with a certain delight, but beſides chears a ſad and ſorrowful Heart; yea, allays all turbulent Paſſions excited in the Breaſt from an immoderate heat and fluctuation of the blood. For ſince the animal Spirits, ſerving for the motion of the *Præcordia*, are derived from the Cerebel; as the perturbations conceived in the Brain, the influence being tranſmitted hither by moving theſe Spirits, in the Fountain it ſelf, transfer the force of their Affections on the Breaſt; ſo the Melody introduced to the Ears, and diffuſed through this Province, does as it were inchant with a gentle breath the Spirits there inhabiting, and compoſes them, called off from their fury, to numbers and meaſures of dancing, and ſo appeaſes all tumults and inordinations therein excited.

From theſe may in ſome meaſure be known the reaſon of the difference, why the hearing Nerves are after a different manner in man and in four-footed beaſts: for, becauſe in theſe there is little need that the audible Species ſhould paſs through the Cerebel, either for the reciprocations of the ſound heard, by the voice, or for the impreſſing there the Tunes of the Harmony (for neither is Muſick required, what ever Poets feign, to the taming the Affections which move the breaſts of beaſts) therefore in theſe (I mean in four-footed beaſts) the annular Protuberance diſpenſing the animal Spirits to the auditory Nerves, and receiving from them the ſenſible Species, requires not ſo ſtrict an affinity with the Cerebel: yea, whenas in may ſuffice, that thoſe Nerves ariſe from the oblong Marrow, yet the annular Protuberance, as it were a common Porch, ought to be prefixed to them; to wit, in which both the Spirits going out from either ſide, and the ſenſible Species to be carried to either, ought firſt to be mixed and united together, leſt otherwiſe every ſound ſhould become double.

Among the Nerves which are ſeen to belong to the Cerebel, and to perform its offices, laſtly follow the eighth or wandering pair, which indeed hath its riſe out of the common Trunk of the oblong Marrow, near the place where the laſt proceſs of the Cerebel is terminated, and over againſt where the pyramidal bodies, being produced from the annular Protuberance, end: ſo that we think theſe Nerves alſo, by that proceſs coming between on either ſide, and alſo perhaps in ſome meaſure through the paſſage of the pyramidal bodies, do derive all manner of influence of the animal Spirit from the Cerebel.

The beginning of theſe conſiſts of very many fibres and filaments or little threads preſently diſtinct one from another; to which belongs, from the very beginning of every Nerve, a noted Trunk ariſing out of the ſpinal Marrow. The deſcription of the wandring pair of Nerves, and its protenſion into the *Præcordia* and ſome *Viſcera*, are added hereafter. For the preſent it ſhall ſuffice, that we take notice, for that as much as this Nerve is beſtowed chiefly on the *Præcordia*, the acts whereof are involuntary, and are performed without our care or knowledge in ſleep as well as waking; and for that the ſame Nerve ſeems to receive the forces of the Spirits wholly from the nearer fountain of the Cerebel; from hence it may certainly be well concluded, that the government or œconomy of the Cerebel regards only the involuntary Function.

So much for the Nerves, which being ſubjected to the Government and Laws of the Cerebel, ſeem to obey and ſerve under it: among which moreover ought to be placed the fourth pair, or the pathetick Nerves of the Eyes, to wit, which ariſing out of the firſt proceſſes of the Cerebel, come between that and the orbicular Proceſſes; of the uſe of which we have ſpoken already. Further, we ſhall here take notice, that ſome other Nerves to be deſcribed below, for that they communicate with the aforeſaid Nerves near their originals, cauſe alſo ſome involuntary acts to be performed; of which ſort are firſt the ninth pair, the ſpinal Nerve acceſſory to the wandring pair, alſo the Nerve of the Diaphragma, and ſome others, as we ſhall ſhew mor at large in the particular Hiſtory of the Nerves.

We may alſo obſerve, concerning the Nerves but now deſcribed, which owe their ſtock to the Cerebel, and ſeem to be deſigned for the offices of the involuntary Function, that ſometimes ſome of them, though of another Dominion, are compelled to obey the beck and government of the Brain: for we are wont to draw the parts of the Face, uſually moved pathetically and unthought of, and alſo at our pleaſure, into theſe or thoſe Configurations or poſtures: we are able alſo in meaſure to alter the motions and actions of the *Præcordia* and *Viſcera* at the will or command of the Appetite. The reaſon of theſe is, partly becauſe the Nerves of either Government communicate variouſly among themſelves with ſhoots ſent forth one to another, ſo that oftentimes the offices of the one are drawn into the parts of the other. But beſides, we have mentioned before, that the ſenſible impreſſion being inflicted on the parts of the involuntary Function, foraſmuch as it is vehement, like a ſtrong waving of water, paſſing through the Cerebel, affects the Brain it ſelf. In like manner it may be thought concerning the motion which belongs to thoſe parts, *viz.* that made after the ordinary manner, that it is performed by the command of the Cerebel. Notwithſtanding ſome more ſevere Edicts of the Brain, by the by-paſſage of the Prominences, belong

alſo

alſo to the Cerebel, and determine the Offices of the Inhabitants of it to be performed at the beck of the Appetite. As every one ſees that violent Paſſions (whether the will be privy or not) eaſily do this; why therefore may not the will it ſelf alſo, as occaſion requires, exerciſe the ſame dominion? But in the mean time, this derogates nothing from the priviledges of the Cerebel, that it may not be called a free and municipal City, and ſo Miſtreſs of the involuntary Function; for that in ſome few it is after the manner of the Brain: becauſe the Brain it ſelf in many things is compelled to ſerve the Cerebel and its Government, as we have already ſhewn, and is neceſſarily bound to it. For the Brain owes much to the Cerebel, foraſmuch as it receives from the vital Function (which is of its Province) the proviſion of the blood, and by conſequence the Tribute of the Spirits produced of it: ſo indeed that both theſe parts, though Principals, perform mutual offices, and as it were in a circle, require and accompliſh ſervices one for another.

CHAP. XVIII.

Of the relation or mutual reſpect of either Appendix of the Cerebel, to wit, of the anterior, which are the orbicular Prominences; and the poſterior, viz. *the Annular Protuberance: Alſo of the remaining portion of the oblong Marrow continued into the Spinal Marrow.*

BEſides the aforeſaid Nerves, to wit, the fourth, fifth, ſixth, ſeventh, and eighth pair which are imployed for the performing the tacit Edicts of the Cerebel for every involuntary Function, and thoſe equal in number to the reſt ſubject to the Brain, that cauſe the Cerebel to have an Empire divided with it; there are alſo ſome Proceſſes and Protuberances, which being placed before and behind the Cerebel, are its Appendixes, that are taken into part of the ſame Office and Miniſtry. The deſcription and uſe of theſe, are already particularly delivered. But for that (as a while ſince we intimated) there happens a certain reſpect or habit between the orbicular Prominences, which is the anterior Appendix of the Cerebel, and the annular Protuberance, which is the other poſterior Appendix of the ſame, and that one part is proportionate to the magnitude of the other; ſo as when the natiform Prominences are greater or greateſt, the annular Protuberance is always ſmaller or ſmalleſt; and on the contrary, they who have this latter in a very great bulk, in them the other is leſſer; and ſo for that either part ſeems to be a peculiar Repoſitory of the Spirits, which belong to the œconomy of the Cerebel, when a greater proviſion of them is laid up in one Store-houſe, therefore there reſides a leſſer in the other; when I ſay there is this kind of conſtant relation found between theſe parts, it yet remains for us to find out for what end this is ſo conſtituted.

Seeing that the animal Spirits are diſpoſed within the ſeveral parts of the Head in diſtinct Schemes of Rays, through which are variouſly tranſmitted, as through Perſpective glaſſes, the impreſſions of ſenſible things and the inſtincts of motions to be performed; it eaſily occurs, that there are commerces had this way and that way in the natiform Prominences between the Brain and Cerebel; and that the Spirits inhabiting the annular Protuberance are *Internuncii* or Meſſengers going between, which transfer the mutual reſpects of the *Præcordia* and *Viſcera*, as alſo of the parts that are wont to be pathetically moved. But if it be inquired into, what kind of commerces and reſpects thoſe are which the Brain carries to the Cerebel, and on the contrary, and that either have to the Organs of the vital and merely natural Function, we ſhall in ſo difficult and very intricate a matter propoſe our Opinion, though with an heſitating and doubtful mind.

We have before intimated, that the orbicular Prominences did deliver to the Cerebel the forces of the Paſſions to be carried from the Brain the *Præcordia*, and did receive from it, and communicate to the Brain the neceſſities of the natural Inſtincts delivered from the *Præcordia* and *Viſcera* to the Cerebel. To theſe moreover we add, that the annular Protuberance ſerves wholly for the ſame offices, though after another manner; to wit, this receives the forces of the Paſſions, as it were at a ſecond hand, from the Deputiſhip of the Cerebel, and tranſfers them then immediately to the *Præcordia*; and this ſeems to be the chiefeſt office of this part. Further, the ſame Ring receives immediately the natural Inſtincts from the *Viſcera* of the middle and loweſt Belly, and impreſſes them on the Cerebel to be conveyed further to the Brain; which kind of uſe it exhibits ſecondarily by affording only a way of paſſage: For indeed ſuch Inſtincts having paſt through the Cerebel, we ſuppoſe to be formed and perfected within the orbicular Prominences, from whence being tranſmitted into the Brain, they draw forth requiſite actions without the previous knowledge of it, or intention of doing.

Hence

Hence it may be ſuppoſed, that the annular Protuberance contains chiefly the animal Spirits which perform the inteſtine commotions of the Affections. In every violent paſſion of the Soul, preſently the *Præcordia* are greatly troubled, to wit, the ſame being variouſly drawn together or ſpread abroad, compel the blood into divers fluctuations; but indeed a great company of the Spirits, ſomewhere got together and ready for Excurſions in a ſet Battel, do perform theſe diſorders and irregular motions of the *Præcordia*; and for that the Spirits can be diſpoſed for this in no other part than here, before the beginnings of the Nerves, conſtituted for theſe offices; therefore this Protuberance in a man, by reaſon of the ragings of the paſſions to be performed by a certain force and incitation, is far greater than in any other Animal. For as he is wont to be ſuddenly and vehemently diſturbed, therefore the Promptuary or Store-houſe is required to be more large, in which a greater plenty of Spirits may be kept, to be beſtowed on ſuch inordinations of the Affections. Next to a man this part is greateſt in a Dog, Cat, and Fox; in a Calf, Sheep, Goat, Hare, and other milder Animals it is very ſmall.

But as the annular Protuberance ſeems to be the chief Organ or Cheſt of the Spirits, from whence the winds of the Paſſions, deſtinated for the exciting the *Præcordia*, are conveyed into the breaſt; ſo we ſuppoſe the orbicular Prominences to be a means of paſſage, and the very inſtruments whereby the inſtincts and neceſſities of the *Præcordia* and *Viſcera* are communicated from the Cerebel to the Brain. Yea, the animal Spirits dwelling in this, as a retiring place, do not only tranſmit theſe kind of Ideas or formal Reaſons of the Inſtincts, but in ſome meaſure form and prepare them for the Brain. For when as ſome brute Animals, whoſe Brain is not imbued with a previous knowledge or practical habits, chuſe and bring forth ſome ſpontaneous actions as it were with judgment and deliberation, certainly we may believe the intentions of theſe kind of acts are ſuggeſted from ſome other place than the Brain, to wit, from the aforeſaid Prominences. Wherefore 'tis to be obſerved, that in ſome Brutes endued with an indocil or dull Brain, the Buttock-like Prominences are greateſt, as may be ſeen in a Calf, Sheep, Hog, and many others; which Animals, as ſoon as they are brought to light, preſently ſeek for their food, and what is congruous for them they readily know. But in a Man, a Dog, Fox, and the like, who are more apt to learn and acquire habits, theſe Prominences are very ſmall; and theſe Animals being newly born, are furniſhed only with a rude and imperfect ſenſe; beſides, they are found wholly unapt to ſeek out their food. Upon this Obſervation (which holds good in moſt Animals which I have yet happened to diſſect) as upon a Baſis or foundation I dare build this kind of abſtruſe Hypotheſis concerning the natural Inſtincts and Affections of the *Præcordia*. For as the living Creatures which are more ſtrong in inſtinct, as Sheep, Hogs, Oxen, Goats, and other ſlow and gentler beaſts, that are not obnoxious to Paſſions, are alſo leſs docile or apt to learn; and on the contrary, they in whom the Affections are wont to predominate, and who are furniſhed with a certain wit, (as beſides Man, are Dogs, Foxes, and ſome other hotter Animals) are leſs powerful in Inſtinct: and as I have obſerved in the frequent Diſſection of all ſorts of Heads, that in thoſe kind of living Creatures, who live rather by Wit than Inſtinct, the annular Protuberance, placed below the Cerebel, was notedly great, and the orbicular Prominences only very ſmall; but in other living Creatures, where the Inſtinct exceeded the wit, and who were leſs prone to ſtrong Affections, the orbicular Prominences were very great, and on the contrary, the ringy Portuberance exceeding ſmall: From hence I was forced to think, that the orbicular or natiform Prominences, where they are great, are inſtead of another or ſupplementory Brain, and the chief Organs of the natural Inſtincts; yet ſo, as theſe parts alſo ſerve for a way or means of paſſage for the transferring the Paſſions from the Brain towards the Cerebel and *Præcordia*; and that (as we have all ready hinted) the greater exiſtency of the annular Protuberance is to contain plenty of Spirits requiſite for the winds of the Paſſions; yet in the mean time, by a further tending forwards or declination of the Spirits inhabiting this, the Species of the natural Inſtincts, being ſent from the *Præcordia* and *Viſcera* paſs through. But however the buſineſs is, becauſe nothing can be certainly affirmed, or by demonſtration, if this our Opinion pleaſe not others, at leaſt it may be pardoned.

There remains not much more to be ſpoken concerning the Offices and Uſes of the Cerebel and its Appendix. Concerning its ſubſtance, there is ſomething more worthy taking notice of, to wit, that it very much differs in this reſpect from the ſtructure of the Brain alſo, for that its cortical little circles are not founded in the ſtretched out Marrow, as the convolutions of the Brain; but being deeply cut in, are diſcontinued in their whole tract: ſo that the whole Syſtem of the Cerebel is as it were a cluſter of Grapes compacted cloſely together; in which, although the Berries be contiguous, yet they remain diſtinct one from another, and bring forth fiſſures through the whole thickneſs of the maſs. Yea the outward ſuperficies of the Cerebel conſiſts as it were of very many Tubercles or little Tad-ſtoles or Puffes which grow together on little ſtalks; and thoſe ſtalks paſs into greater branches, and they at length being bipartite or twofold, go together into two larger Marrows near the bottom of the Cerebel, in either of which are three diſtinct medullary Proceſſes: of which threefold proceſſes on either ſide we have already ſpoken. But of theſe concerning the uſe of the Cerebel in general, we ſhall yet further advertiſe you, that as very much of its ſubſtance is cortical, it begets animal Spirits in great plenty, to which in the circulating there is not granted, as in the Brain, an equally great ſpace; for that there ſeems not to be much need of it in the animal Government. For the Spirits ſo produced in the Cerebel plentifully by a perpetual emanation, ought to flow outwardly for the offices of the natural and vital Function: but more inwardly for the impulſes variouſly ſent into them, they admit certain undulations or wavings, by which ſome occaſional acts of the involuntary Function are brought forth, as is ſhewn before.

But

But as it is manifeſt enough, that the animal Spirits are generated within the cortical little circles of the Cerebel, it doth not ſeem needful that we ſhould ordain their Work-houſe in the Ventricle ſubject to its frame. For that Cavity (as we have already ſhewn) is only an empty ſpace, which lying under its double little foot and medullar Trunk, comes between it and the overlying bunching out of the Cerebel. But indeed there belongs to this beſides a certain uſe, to wit, that the ſerous watry heap laid aſide out of the Glandula's and infoldings of the Veſſels, as alſo from the ſubſtance of the Cerebel, being made overmoiſt, diſtilling down, might ſlide into this Ciſtern. From whence, leſt it ſhould flow down upon the beginnings of the Nerves, by a reſtraining Membrane it is compelled into the hole of the ſtrait Den lying under the orbicular Prominences; and from thence is received from the declining aperture of the Tunnel, and carried out.

Below the Cerebel, the oblong Marrow going forward with the reſt of its tract even to the hole of the hinder part of the Head, ends at length in the ſpinal Marrow: but in its Trunk, as yet contained within the Skull, beſides the Nerves and Proceſſes but now recited, the beginnings of the ninth and tenth pair of Nerves are alſo radicated. Of what there will be hereafter a proper place to ſpeak, when we ſhall inſtitute the whole Neurology or the Doctrine of the Nerves. In the mean time, we ſhall take notice of the beginning of the ninth pair, which is peculiar in Man, and different from what is found in Brutes: To wit, in Man below the origine of the eight pair, a certain Protuberance grows to either ſide of the oblong Marrow. Out of that four or five diſtinct Fibres do come forth; one or two of which binds about the Vertebral Artery paſſing through it, but all grow together into the ſame Trunk, which is the Nerve of the aforeſaid pair. This Protuberance, the *Pia Mater* being pulled away, may be eaſily ſeen, and ſeems to be the Repoſitory or Store-houſe of the Spirits deſtinated to this Nerve.

For as this Nerve is beſtowed on the Tongue and its Muſcles, and ſo conduces chiefly to the performing of ſpeech in Man, who hath a greater and more frequent uſe and exerciſe of the voice, there ſeems to be need of a great proviſion of Spirits, plenty of which ought always to be in a readineſs. But in Brutes, who have none, or a rarer neceſſity of the voice, ſuch a Protuberance is wanting, becauſe it is not required in them that the Spirits ſhould be gathered together by heaps, as it were in a certain Porch, before the Organs of the Voice, but that it may ſuffice for them to be called forth by degrees out of the common tract of the oblong Marrow. Further, whereas ſome fibres of this Nerve bind about either Vertebral Artery, unleſs I am deceived, that is ſo ordained for this end, leſt perhaps in ſpeaking, when at any time we are more vehemently moved, the blood being ſtirred up, might ruſh upon the Brain with a torrent. For this Nerve binding about the Vertebral Artery, as it were with a bridle, and ſo as a Moderator not only of the Tongue, but alſo of the Blood, reſtrains its more rapid influence. After the ſame manner, and for no other ends do recurrent Nerves, deſtinated to ſome part of the ſame office, variouſly bind about the Trunk of the great Artery, as ſhall be ſhewn afterwards.

As ſoon as this inferior portion of the oblong Marrow is uncloathed from the *Pia Mater*, the pyramidal bodies come in a view otherwiſe lying hid. Theſe in all Animals, endued with the annular Protuberance, are conſtantly found; alſo as that Protuberance is bigger, ſo theſe bodies appear more noted: but indeed in a Man and a Dog they ſeem like two large Nerves, which being produced out of that Ring, end over againſt where the eighth pair ariſe in ſharp points. If the uſe of theſe be ſought into, it is moſt likely, that the animal Spirits ſuperabounding in the annular proviſion or ſtore, do flow out as it were by theſe Emiſſaries, which Spirits however run into the beginnings of the eighth pair placed near, and ſo are beſtowed by their proper means on the offices of the involuntary Function.

Although the oblong Marrow retains not its name beyond the limits of the Skull; yet it is the ſame ſubſtance, which from thence being continued further into the cavity and utmoſt receſſes of the whole Spine or Back-bone, is called the Spinal Marrow: but it is brought forth for this, that the Nerves to be diſtributed into the Limbs and Members more remote from the Head, might more commodiouſly ariſe out of the ſame medullar ſubſtance ſtretched out into the neighbourhood of every part. Indeed all this whole medullar Trunk, which is continued from the bottom of the Brain even to the *Os ſacrum*, ſeems like the Pneumatick Cheſt, or Bellows of a pair of Organs, which includes the blaſt or breath deſtinated to every Pipe; for in like manner the animal Spirits are contained in this marrowy tract, which blow up and actuate all the Nerves hanging thereto, as occaſion ſerves.

If you behold the origine of the whole, it ſeems that the whole frame both of this oblong Marrow and the ſpinal, is of a medullar or marrowy ſubſtance, every where growing diſperſedly through the Brain and Cerebel, and then being gathered more round together in the middle of either, becomes as an heap. For the Marrows beſmearing all their folds and turnings about, are as ſo many little rivers, which ſpringing from thence, begin to be congregated in the middle, and to be poured out in one great one; but being from thence united, they make the oblong Marrow, as it were the chanel of the Sea, big enough for the motion or ebbing and flowing and reciprocation of the animal Spirits: which belly or chanel, however ſtretching it ſelf further beyond the Skull, is increaſed into the ſpinal Marrow, as it were the boſom or proceſs of the former.

But as the medullar tracts, beſmearing the folds and convolutions of the Brain and Cerebel, unfold themſelves into their middle Marrows and medullar Trunk, and ſo the Spirits ſpringing diſperſedly from their firſt fountains, congregate as it were into a certain diffuſed Sea; ſo from this Sea, cauſing an ebbing and flowing, or a continual or very frequent influence of the animal Spirit, the ſame Spirits flow out into the depending chanels of the nervous Syſtem.

Concerning

Concerning this part of this Marrow, which being included in the long boſom or chanel of the *Vertebræ* or Back-bone, and according to all their joyntings, being marked with as it were knotty proceſſes, is called the Spinal, there occur not many things worthy conſideration, beſides what are commonly known. The figure, ſituation, as alſo the body of this, in its whole tract, are known generally to be cloven in two, not only by Anatomiſts, but by every Butcher. The ramifications or branchings of the Nerves, proceeding from the ſpinal Marrow, are delivered hereafter. Concerning its conformation ſomething peculiar occurs. For as the ſpinal Marrow is as it were the common paſſage or chanel of the Spirits flowing out of the Head into the Nerves, it may be obſerved, that this chanel, not after the uſual manner of other paſſages, where many rivers flow in, doth ſwell up more; but on the contrary, in what place it hath more and greater Emiſſaries, its magnitude is increaſed; for in thoſe parts of the ſpinal Marrow, out of which the brachial and crural Nerves ariſe, (or thoſe Nerves belonging to the Arms and Legs, whoſe beginnings are more and larger) its Trunk becomes much thicker than in the reſt of the frame or ſubſtance. The reaſon of this is, becauſe within the medullar tracts the animal Spirits run not, nor paſs through with ſo ſwift a paſſage, but for the moſt part flowing leiſurely from their Fountains, when they have filled the whole ſpace, they ſtay therein; and as many Spirits, upon occaſion offered, are wont to be beſtowed on every work, thoſe remaining there in readineſs frame certain convenient Promptuaries where they may divert themſelves. Wherefore we ordinarily obſerved, not only of this Marrow, but of the Nerves themſelves, that as often as a ſmall branch is diſtributed into many ſhoots or ſuckers to be ſent forth here and there, always in the very knot of the diviſion there grows a far greater fold than in the reſt of the Trunk of the Nerve; ſo that 'tis a wonder from whence the Nerve ſhould acquire ſo in the middle of its paſſage a new ſubſtance and more ample bulk. But of theſe things and others belonging to the Doctrine of the Nerves, it behoves us to diſcourſe in the following Chapters.

CHAP. XIX.

Of the Nervous Syſtem in general, where its parts (which are the Nerves and Fibres) being deſigned, a proſpect of the whole Animal Goverment is exhibited.

WHen as hitherto having beheld the ſeveral Regions of the Brain it ſelf, the Cerebel, and medullar Appendix, and the proviſion and offices of them all, we have deſigned or drawn forth the uſes and employments alſo of the parts and proceſſes, and the ſanguiferous Veſſels belonging to every one of theſe; it is now time for me to ſtop and retire into the Port from this troubleſom and intricate Sea of Diſquiſition: But indeed, becauſe I find that I have not yet reached to the fartheſt ſhores and utmoſt parts, but that beyond this Sea, which we have ſailed through, as yet the nervous Syſtem, and very many Creeks or Boſoms, Meanders, and highly intricate Receſſes or private places in it remain to be viewed; therefore although we know it is difficult to proceed with full Sail, we have reſolved to undertake the task of the Doctrine of the Nerves; and the rather, becauſe without the perfect knowledge of the Nerves, the Doctrine of the Brain and its Appendix would be left wholly lame and imperfect; for neither what hath already been delivered concerning them can be ſufficiently underſtood or illuſtrated, nor (which I chiefly deſire, and is the end of the former Diſquiſitions) without thoſe things before known can the Pathology of the Brain and nervous ſtock be rightly inſtituted. And indeed there are many things which might eaſily deter any one from ſuch an undertaking: to wit, the hardneſs of the work, and full of hazard; which promiſes at firſt-ſight more difficulty and thorny labour, than pleaſure or profit. Then ſome will object, that this Province is already ſo perfectly cultivated, and adorned by former Anatomiſts, that by a repetiton of the ſame, I may ſeem to have medled with a thing done to my hand. But I may readily anſwer to theſe, firſt, That the Anatomy of the Nerves yields more pleaſant and profitable Speculations, than the Theory of any parts beſides in the animated Body: for from hence the true and genuine Reaſons are drawn of very many Actions and Paſſions that are wont to happen in our Body, which otherwiſe ſeem moſt difficult and unexplicable; and no leſs from this Fountain the hidden Cauſes of Diſeaſes and their Symptoms, which commonly are aſcribed to the Incantations of Witches, may be found out and clearly laid open. But as to our Obſervations about the Nerves, from our following Diſcourſe it will plainly appear, that I have nor trod the paths or footſteps of others, nor repeateed what hath been before told.

Therefore

Therefore, that according to our determination we may enter upon the explanation of the nervous Syſtem, we ſhall comprehend under this name all parts, upon which gifted with the animal Spirit, Motion and Senſe neceſſarily and immediately depend, to wit, for the performing either one only, or both together in the whole Body. But theſe kind of parts, in reſpect of the Head and marrowy Appendix, are like a branching ſtock or imps growing out of the trunk of a Tree: for ſuppoſing that the cortical ſubſtances of the Brain and Cerebel are in the place of roots, and that the ſubſtances every where medullar are taken for the ſtock or pith; the nervous germination or budding forth expanded into divarications of Nerves and Fibres, will appear like ſo many little branches, twigs, and leaves. Or if the Head containing in it ſelf the chief part and power of the ſenſitive Soul, be taken for the body of ſome Luminary, as of the Sun or a Star; the nervous Syſtem ſhall be that radiant or beamy concretion compaſſing it about. Becauſe the animal Spirits flowing from the Brain and Cerebel, with the medullar Appendix of either, as it were from a double Luminary, irradiate the nervous Syſtem, and ſo conſtitute its ſeveral parts, the Organs of Motion or Senſe, or of both together, as hath been ſaid.

The parts of the nervous Syſtem, as a radiant or beamy texture, are either primary, *viz.* the bodies themſelves of the Nerves, into which the animal Spirits immediately flow from the Head and its medullar Appendix; or ſecondarily, which are Fibres planted or interwoven in the Membranes, muſculous Fleſh, Tendons, and ſome of the Parenchyma, which alſo contain in themſelves animal Spirits; but they receive them not but mediately and ſecondarily derived from the Head through the bodies of the Nerves.

We have already ſhewed that the animal Spirits are procreated only in the Brain and Cerebel, from which they continually ſpringing forth, inſpire and fill full the medullar Trunk: (like the Cheſt of a muſical Organ, which receives the wind to be blown into all the Pipes) but thoſe Spirits being carried from thence into the Nerves, as into ſo many Pipes hanging to the ſame, blow them up and actuate them with a full influence; then what flow over or abound from the Nerves, enter the Fibres diſperſed every where in the Membranes, Muſcles, and other parts, and ſo impart to thoſe bodies, in which the nervous Fibres are interwoven, a motive and ſenſitive or feeling force. And theſe Spirits of every part are called Implanted, foraſmuch as they flow not within the Nerves, as the former, with a perpetual flood; but being ſomething more ſtable and conſtant, ſtay longer in the ſubject bodies; and only as occaſion ſerves, *viz.* according to the impreſſions inwardly received from the Nerves, or impreſſed outwardly by the objects, are ordained into divers ſtretchings or carryings out for the effecting of motion or ſenſe either of this or that manner or kind.

Indeed the animal Spirits flowing within the Nerves with a living Spring, like Rivers from a perpetual Fountain, do not ſtagnate or ſtand ſtill, but ſliding forth with a continual courſe, are ever ſupplied and kept full with a new influence from the Fountain. In the mean time, the Spirits in the reſt of the nervous kind, eſpecially thoſe abounding in the Membranes and muſculous ſtock, are like Ponds and Lakes of Waters lately diffuſed from the chanels of Rivers, whoſe waters ſtanding ſtill are not much moved of their own accord; but being agitated by things caſt into them, or by the blaſts of winds, conceive divers ſorts of fluctuations.

But becauſe there is no light difference between the motions and conſiſtency of the Spirits and of Waters, perhaps it will better illuſtrate the matter, if the Spirits of either kind, to wit, the inflowing and implanted, are compared to the beaming forth of divers rays of light. And ſo when light is let into a dark chamber, and preſently inlightens the whole, we may conceive the particles of the light ſo ſwiftly diffuſed to be of a twofold kind; to wit, ſome are bodies ſent from the light it ſelf, which diffuſe themſelves every way into an Orb; and other luminous particles are as it were Etherial little bodies exiſting before in the pores of the Air, which being agitated by the former, and as it were inkindled, cauſe as it were a flamy, though moſt thin contexture, ſtretched out in the whole clearneſs. After the like manner, the animal Spirits flowing from the medullar ſubſtance into the Nerves, are as it were rays diffuſed from the light it ſelf, and the other Spirits every where abounding in the Fibres, are as ſo many lucid particles included and implanted in the Air, which are actuated by the former, and being ſtirred up by them into motion, perform the acts both of the ſenſitive and locomotive Faculty.

That it may better appear by what means the animal Spirits do irradiate and ſwiftly paſs through the parts of the nervous Syſtem, both primary and ſecondary; ſo that light is ſcarcely carried ſwifter through a diaphanous Medium, than the communication of the Spirits is made from one end of the nervous Syſtem to the other; it will be requiſite to inquire here a little concerning the Origine of the Nerves and nervous Fibres, alſo of their Fabrick and Conformation, to wit, what pores and paſſages either of theſe bodies have, and how diſpoſed for the paſſing through and commerce of the animal Spirits.

As to the Nerves, it is manifeſt from what hath been ſaid, that all of them are produced immediately out of the medullar Trunk or its proceſſes; ſo that as theſe parts are the common and broad roads which lead both from the Brain and from the Cerebel, all the Nerves are particular paths reaching out from them on every ſide into the ſeveral Regions of the animated Body. Wherefore the ſame Marrow, which is the original of every Nerve or Sinew, foraſmuch as it is drawn into a more thin thread, conſtitutes the matter of the ſame Nerve; which indeed, that it may be made more ſolid and compact, is cloathed with a peculiar production of the *Pia Mater*, for as from a Silver maſs gilt or inriched with

Gold, all the threads produced from it are gilded; ſo the ſame Membrane, which covers the medullar Trunk, is produced together with all the Nerves coming out from the ſame, and cloathes them all. Further, very many Nerves ariſing together out of that marrowy beginning, go forth as it were by bands; which notwithſtanding, for the ſake of the better paſſage, being preſently united and carried out of their bony Cloiſter, are included in a common Coat taken from the *Dura Mater*. For we ſuppoſe (which alſo ſhall be more clearly ſhewed anon) that all the Nerves, deſtinated to any parts or every particular member, do ariſe diſtinctly and apart, and ſo remain in their whole paſſage. But in that oftentimes a Nerve appearing as it were one Trunk, afterwards ſeems to go into many branches, it is becauſe thoſe branches being indeed ſingular, and divided in the whole paſſage, are collected as it were into one bundle; for ſometimes we have ſeparated thoſe Nerves, ſeeming to grow together as it were into one rope or cord of of a Nerve, one from another, dividing them to their very original; for neither otherwiſe could the Inſtincts of the Motions to be performed be carried ſo reſpectively to theſe or thoſe parts, ſeparate one from another, to which the branches of the ſame Trunk belong.

The paſſages of the Nerves are not bored through as the Veins and Arteries; for the ſubſtance of thoſe are not only impervious to any Bodkin, but no cavity can be ſeen in them, no not by the help of Spectacles or a Microſcope. As to what belongs to the ſmelling little Pipes, they ſeem to be ſo made, not for the paſſage of the animal Spirits, but that ſome ſeroſities might ſlide down that way: but the Spirits themſelves are carried in the ſides, and not in the cavity of either Pipe; but the ſubſtance of the other Nerves appears plainly firm and compacted, that the ſubtil humor, which is the Vehicle of the Spirits, may paſs through their frames or ſubſtances, even as the ſpirits of Wine, the extended ſtrings of a Lute, only by creeping leiſurely through. Hence it may be argued, that becauſe the animal Spirits require no manifeſt cavity within the Nerves for their expanſion; neither is there need of the like for them within the ſubſtance of the Brain; but that the Ventricles, commonly ſo called, ought to be deputed to ſome other office than this.

But the Nerves are white, ſmooth, and round bodies: within the Skull and nigh their beginnings, being as it were only covered with the *Pia Mater*, they are ſoft and eaſily broken; without this, for that many of them are for the moſt part gathered together, and alſo cloathed with the *Dura Mater*, they become ſomewhat hard and more tenacious. The Nerves themſelves (as may be diſcovered by the help of a Microcoſm or Perſpective-glaſs) are furniſhed throughout with the pores and paſſages, as it were ſo many little holes in a Honey-comb, thickly ſet, made hollow, and contiguous one by another; ſo the Tube-like ſubſtance of them, like an *Indian* Cane, is every where porous and pervious. Within theſe little ſpaces the animal Spirits or very ſubtil little Bodies, and of their own nature ever in a readineſs for motion, do gently flow; to which is joyned, both for a Vehicle, as alſo for a Bridle or ſtay, a watry Latex, and that it ſelf of very ſubtil parts. This Humor diffuſes, with its fluidity the Spirits through the whole nervous Syſtem; alſo by its viſcoſity retains them, that they be not wholly diſſipated, but as it were in a certain *Syſtaſis* and continued Series; for it ſeems, that without ſuch an Humor the Spirits could not conſiſt within the nervous ſtock, but they would vaniſh away into Air. Further, the ſame Humor is no leſs required for the paſſing through of the ſenſible Species: becauſe the animal Spirits, we ſuppoſe, like the rays of Light, to be diffuſed through the whole nervous Syſtem; and thoſe rays, unleſs the humid particles of the Air be mingled with them, do not eaſily tranſmit the forms or images of things; as is obvious in an Optick Scene, which is hid or ſhadowed by the clear beams or brightneſs of the Sun. And in like manner, from the defect or depravation of the nervous Juyce, we can readily ſhew, that the inordinations of the animal Spirits, and oftentimes moſt horrid diſtempers of the Brain and the nervous ſtock do ariſe.

This nervous Juyce being derived from the Brain and Cerebel into the medullar Appendix, is carried from thence by a gentle ſliding down through the Nerves even into the whole nervous ſtock, and waters its whole Syſtem. Upon the equal emanation of this depends the expanſion of the animl Spirits through the whole; and the ſubſtance of theſe, yea the Hypoſtaſis of the ſenſitive Soul it ſelf is founded on the diffuſion of the ſame humor. The animal Spirits being left to themſelves, follow the motion of this Juyce, and flowing together with it in the ſame courſe, are pleaſingly or quietly expatiated; but in the mean time, as occaſion is offered, the ſame Spirits, as a breath moving upon thoſe waters, conceive other ſpreadings abroad, and thoſe more rapid. For as in a River, from winds or any thing caſt in, divers undulations or wavings are ſtirred up; ſo the animal Spirits being raiſed up by objects for the performing the offices of ſenſe and motion, do tend this way or that way to and fro within the nervous ſtock, and are agitated hither and thither by other means.

But to return to the parts of the nervous Syſtem, beſides the Nerves themſelves, Fibres alſo being diſperſedly interwoven in the Membranes, the muſculous Fleſh, the Parenchyma, and other parts, and united in the Tendons, are the Organs of ſenſe and motion. Yea, the acts of their faculties are principally and more immediately executed by the Fibres than the Nerves; for they, by drawing together the Muſcle and other motive parts, cauſe the motion it ſelf; but the Nerves only carry from the Head the inſtinct for the performing of that motion. In like manner, in Senſation the Fibres receive firſt of all and immediately the impreſſions of ſenſible things, and expreſs the ſame (as muſical ſtrings do the ſtrikings of a quill or fingers) by an intrinſecal modification of the Particles, and repreſent the various approaches of the object by the like motion of the Fibrils, as by a moveable and fluid Character, whoſe Idea the Nerves transfer only to the Head.

Concerning

Concerning the nervous Fibres it behoves us to inquire from whence they have their riſe? For it appears plainly, that they ariſe not immediately from the Head or its medullar Appendix; not is it leſs improbable, that they are produced (as 'tis commonly ſaid) from the Nerves: becauſe what is aſſerted, that the Fibres are productions of the Nerves, and little bits or pieces of them torn off, as it were into hairy branches, ſeems unlikely; for that the Fibres in ſome parts, being placed nigh, exceed in their bulk the magnitude of the Nerve that is brought to that part, at leaſt an hundred-fold: which thing appears clearly from the Tendon of every Muſcle, which being made up of united Fibres, is obſerved to be far greater than the Nerve inſerted to it. And indeed for almoſt the like reaſon we are induced to think the nervous Humor it ſelf alſo, whereby the Membranes and muſculous Fibres are wont to be watered, to be derived unto them not by the only means and paſſage of the Nerves; becauſe it is heaped up much more plentifully and in more abundance than can be carried thither through thoſe narrow paſſages, as appears clearly in Ulcers of the Kings-Evil, or in Impoſtumes or Wounds of the Tendons and nervous parts, in which a glutinous Humor drops forth in ſo great abundance, that all the Nerves of the whole Body could ſcarce be able to ſupply it.

Wherefore concerning theſe, it ſeems that we may affirm, that the Fibres are not continued portions of the Nerves broken off into little hairy ſtrings or Capillaments; and that all the Fibres originally proceed not from the Nerves, becauſe ſome of them, *viz.* thoſe interwoven to the Heart and its Veſſels are of equal birth with the Nerves themſelves, and coexiſt with them together from the beginning. However the moſt Fibres, as to their production, depend upon the Nerves; and all, which way ſoever brought forth, receive conſtantly from the Nerves the forces and ſupplements of the animal Spirits, and alſo Inſtincts of the Motions to be performed by them.

Therefore to recount the births or kinds of Fibres; they are firſt either ſpermatick and firſt begotten, the rudiments or firſt beginnings of which being of the like antiquity as the Heart and Brain, placed in the Conception, afterwards leiſurely increaſe; to wit, ſuch are, as hath been ſaid, thoſe in the Heart it ſelf in its depending Veſſels, the Membranes and ſome other parts, which form the firſt ſtuff or threads of the Embryo: or ſecondly, other Fibres are produced ſecondarily, and by a ſecond birth; of which ſort chiefly are ſuch which are interwoven into the parts taken for the compleating of the animal Fabrick, and eſpecially thoſe termed Sanguineous, which we think to be begotten after this manner.

The Heart and Brain, with the Arteries and Nerves hanging to them, are primigenious parts, and highly original; but theſe, for the ſecond birth of others, and for the nutrition and increaſe of all the ſenſitive parts, diſtribute a twofold humor: *viz.* one ſpirituous and endued with very active Particles which perpetually flow, though but in a very ſmall quantity, through the paſſages of the Nerves from the Brain and Cerebel; and the other flow and ſofter, which being every where laid aſide through the Arteries from the bloody maſs, is rendred more plentifully. This latter being of it ſelf dull and thicker by much, is actuated by the former, and being imbued by it, as by a certain Ferment, acquires ſtrength and power of growth or vegetation. But indeed the nervous Juyce, foraſmuch as it diffuſes with it ſelf the animal Spirits, imparts to every part, beſides the faculties of Motion and Senſe, the determinations alſo of form and figure. Further, whilſt that, being joyned to the other arterious humor, is diſpoſed into the ſubſtance and matter of the member or part to be nouriſhed, it forms ſome tracts as it were, to wit, the Fibres themſelves, in which the animal Spirits, coming together with them, reſide and are expatiated. Theſe twofold or twin humors, coupling together in every ſenſitive part, conſtitute a liquor truly nutritious, to wit, which is both ſpirituous and nouriſhable. And in truth, both theſe Juyces, *viz.* the nervous and arterious, being married together, are as it were the male and female ſeed, which being mingled in a fruitful womb, produces the plaſtick Humor, by thoſe virtue the living creature is formed and increaſes. Hence may be obſerved, as the particles of the ſpirituous liquor, or of the other more watry juyce (*viz.* this latter being ſupplied from the Arteries, or that from the Nerves) are ſtrong or excel, as to their properties or powers, all living creatures become more or leſs nimble, active, and ready to any motion and labour. Beſides, from the default or depravation of the one and other humor excelling, the ſorts or kinds of this or that diſeaſe are excited; concerning which, and alſo what belongs to the explication of the nutritious Humor, we may perhaps have ſome other time occaſion to diſcourſe.

The animal Spirits which enter and fill the ordained ſeries of the Fibres as ſo many little places, flow thither by the paſſages of the Nerves; notwithſtanding the Spirits which are ſeated in the Fibres, interwoven with the muſculous ſtock, receive nouriſhment, yea and as it were auxiliary forces, from the arterious blood there plentifully flowing: whereby indeed both the Spirits themſelves acquire for the performing of Motions a greater force and as it were elaſtick; ſo that their force being ſtirred up by a ſtrong endeavour, it ſeems like the exploſion of Gun-powder; and alſo the ſame Spirits being continually conſumed within the Muſcles more profuſely than is wont to be in the Membranes and other parts, are in ſome meaſure made up or repaired from the bloody ſuſtenance: becauſe whenas the arterious Juyce joyns more plentifully with the nervous flowing within the ſanguineous parts, it may be well thought, that it alſo lays upon the Spirits brought thither with it, as it were ſome nitroſulphureous particles, and intimately fixes them on them; and ſo, by reaſon of this Copula, highly flatuous and apt to be rarified, the Spirits themſelves become there more active, ſo that in every motive endeavour, whereby the Muſcle is ſuddenly intumified, they, as if inkindled, are exploded. Moreover, a ſudden refection of the conſumed or waſted Spirits, after great exerciſe or labour, is for this reaſon alſo performed by the blood; for that the ſpirituou

particles being left and forſaken by motion, preſently a new Copula of the ſame kind of matter, apt for exploſion, is joyned to them. For it is not poſſible, that the immenſe loſs of Spirits which happens in hard labours (if they were wholly deſtroyed) in ſo ſhort of time, ſhould be able to be reſtored by ſupplements coming only through the Nerves. We ſhall diſcourſe more largely of theſe things, if at any time hereafter we ſhall treat of the Motions of the Muſcles.

The animal Spirits being diſpoſed within the ſeveral Muſcles, according to the ſeries of Fibres, ſeem as it were ſo many diſtinct Troops or Companies of Souldiers; all which being ſet as it were in a Watch-tower, are ordained, as a new impreſſion is carried to them by the Nerves, either from the objects outwardly, or more inwardly from the Head, forthwith into various forms and peculiar orders for the performing of motion or ſenſe of this or that kind. The carriage or behaviour of theſe is worth the ſeeing in an animal newly killed and its skin taken off. For when life periſhes, and all the force of the Spirits flowing in through the Nerves hath quite ceaſed: yet the Spirits implanted into the whole Body breaking forth from the Muſcles, ſtill move and ſhake them, and force them into ſeveral Convulſions and trembling motions.

From what hath been ſaid we may gather, what the diſpoſition or order of the animal Spirits may be in the whole animal Body: to wit, thoſe procreated in the cortical ſubſtance both of the Brain and Cerebel, are congregated into the middles of either, as it were into diſtinct Empories or Marts; and an expanſion being made in either, they cauſe certain interior powers of the Senſitive Soul to be exerciſed; yet the ſame Spirits, affecting more room, enter the oblong Marrow (as it were the Cheſt, as hath been ſaid, of a muſical Organ) and fill it full; within which flowing, they carry to and fro the impreſſions of ſenſible Things and the Inſtincts of Motions. From the oblong and ſpinal Marrow the ſame Spirits, unleſs when they are otherwiſe buſied, tending outwardly, flow towards the ſeveral parts of the whole Body; which notwithſtanding wandring ſo out of doors, becauſe they paſs through very ſtrait ways in their paſſage, to wit, the ſlender bodies of the Nerves, they break not forth in heaps, or in a thick troop, but only contracted orderly, and as is were by bands or diviſions: but they being carried beyond the extremities of the Nerves, and there poſſeſſing the Membranes, Muſcles, and other ſenſible parts, dilate themſelves as it were into a moſt ample field, and with a very diffuſe Army they dwell in the Pores and paſſages of the Fibres planted every where about; where alſo being endowed from the blood with new food, they become more lively and more expeditious or ready for the deſigned offices.

Here perhaps it may be demanded, how the animal Spirits, diffuſed in ſuch numerous troops through the habit of the Body, are able to be ſupplied by ſo ſtrait chanels of the Nerves? To which we reply, That thoſe which reſide more outwardly do not quickly evaporate, nor are remanded back by Circulation: wherefore when all the Fibres are filled by an influx of the Spirits made by little from the beginning, very ſmall ſupplements ſuffice to repair their expence: For neither are thoſe dwelling more outwardly, for that they are repaired by the bloody food, much conſumed, though in frequent action.

Hence may be noted the difference between the diſtributions of the blood and animal Spirits. That Latex, becauſe it is reduced in a circle, its Veſſels are in the whole paſſage proportionated as to the bulk of the Trunk and the branchings ſent from it, to wit, ſo that the branches of the great Artery, being carried from the Heart, contain at the leaſt ſo much of the blood, as the ſhoots reaching forth from them, into all the parts. But becauſe the animal Spirits being once begotten and carried more outwardly, ſubſiſt longer there, and evaporate very ſlowly and by little and little; therefore the Veſſels carrying them, *viz.* the Nerves, in reſpect of the Fibres receiving them, are made much leſſer in proportion; leſt perhaps by too great a ſupplement of the animal Spirits, and the too thick gathering of the freſh ones ſtill into the nervous parts, the Army of the Veterans, before inſtructed, ſhould be confounded, and ſo the orders of all being diſturbed, the exerciſes of the animal Function ſhould be performed any now. For indeed when at any time the Spirits are made too ſharp, ſo that being therefore ſtruck as it were with madneſs, they ruſh upon the nervous Syſtem with tumult and impetuoſity; from hence a great unquietneſs and continual throwing about of the Members are wont to be excited, to which ſometimes madneſs and fury ſucceed.

In the order and ordination of the animal Spirits, ſuch as was but now deſcribed, the *Hypoſtaſis* or the Eſſence of the ſenſitive Souls conſiſts to wit, which is only a certain *Syſtaſis* or ſhadowy ſubſiſtence of thoſe Spirits, which like Atoms or ſubtil Particles, being chained and abhering mutually one to another, are figured together in a certain Species. Moreover, the faculties of the ſame Soul depend upon the various *Metathesis* and geſticulation of thoſe Spirits within the aforeſaid Organs of the Head and nervous Syſtem. But the conſideration of this Soul and its powers requires a peculiar Tract, which hereafter (God willing) we intend; in the mean time, our Method demands of us, that (accorging to our weak skill) by the cenſe or numbering of the Nerves, being particularly made, we ſhould deliver an exact Neurology or Doctrine of the Nerves.

But for that in the premiſed general conſideration of the Nerves and Fibres, there was mention made of the nervous and nutritious Juyce; notwithſtanding what belongs to their powers and natures, hath been neither fully nor clearly enough delivered; therefore we will a little divert here, and make it our buſineſs to inquire what ſort of Juyces and Humors are carried into the parts of the animated body for their nourihment, and by what ways or paſſages: then this difficulty being removed, a plain and eaſie way leads into the Doctrine of the Nerves.

CHAP.

CHAP. XX.

Of the Nervous Liquor, and whether that or the bloody Humor be Nutritious.

SInce the Circulation of the Blood was made known, and it hath been plainly made appear, that it did no where ſtagnate and ſtand ſtill long, but was carried in a reciprocal motion, always as in a circle; it began to grow doubtful, whether its *Latex* is nutritious or not. For beſides, that the more rapid courſe of the blood, as of a torrent, might ſeem to wear the banks which it flowed between, and to carry away ſome Particles from them, rather than to be able to affix any thing to them; the ſubſtance it ſelf alſo of the blood, for that it is more torrid and uneven, is thought to be altogether unfit for nutrition. Wherefore that a Juyce may be found more convenient or fit for this office, the paſſages and hidden receſſes of the Nerves are to be viewed; and as a certain Latex is found to flow within their Pores and paſſages, preſently the blood being rejected, that nervous humor is gifted with the title of nutritious: but yet by what right, and after what manner nutrition is performed, ſhall be our preſent purpoſe to inquire.

And here firſt of all, that we may take the part of the blood, it will be eaſie to ſhew, that there is matter contained in it fit enough for the nouriſhment of the body, and a ſufficient ſtore of it. For beſides the ſulphureous ſubſtance of the blood, which within the fire place of the Heart, with a continual inkindling, and by that means deflagration in the Veſſels produces life, and in the more perfect Animals heat, there is found alſo a certain other humor ſoft and alible, which in the Circulation, being diſtributed through ſeveral parts of the Body, by increaſing them adds nouriſhment and bulk: yea the deflagration it ſelf of the blood, plainly as a Kitchin-fire in dreſſing meat, as it were boils and prepares this humor, whereby it more eaſily is aſſimilated into the ſubſtance of every part to be nouriſhed. Hence it comes to paſs, that by reaſon of a defect of heat in the blood, no leſs than of exceſs, nutrition is often hindered. But that this kind of alible Juyce is contained in the blood maſs, the *Anatomy* or ſpontaneous *Analyſis* of its *Latex* ſufficiently declares; for the extravaſated blood, when it goes into parts of its own accord, this liquor being disjoyned from the purple thick part, and ſwimming a top of it, appears clear or limpid; but by reaſon of its more thick contents, to wit, the nutritious Particles, like the white of an Egg, it is eaſily made thick, and grows white by a gentle heat: which thing appears by this familiar Experiment, to wit, if you ſhall evaporate a little of it only in a Skillet over the fire, the whole liquor will preſently grow together into a white Gelly. By this liquor, as the blood is more or leſs imbued with it, living Creatures grow and become more fleſhy or lean: for both the blood of younger Animals being looſned from cold, is wont to ſhew much more of this kind of white than more ancient or older Creatures: and we may take notice daily at our Tables, that very much of this kind of Gelly comes out of the fleſh of a Lamb or Calf being boiled or roaſted, and nothing almoſt from Mutton or Beef, eſpecially if old. Therefore we may lawfully ſuppoſe, that the blood is truly nouriſhable; and that the whole, or at leaſt the greateſt part of the matter, for the adding bulk or ſubſtance to every part, is diſpenſed from it: but if at any time it be defective in this its office, that happens not out of the natural unfitneſs of it, but becauſe its diſpoſition is ſometimes depraved, and as the Stomach labouring with ſome vice, rejects or perverts the Chyle to be cooked by it.

But the blood, as it is not the only and alone humor, which is diſtributed in the animated Body, ſo neither ſeems it able to perform alone and of it ſelf the whole office of nutrition. For beſides that, being diffuſed through the Arteries and Veins, another Latex is every where diſpenſed from the Head through the Nerves; which ſhall be ſhewn to afford ſomething at leaſt to nouriſhment.

As to the firſt, there are many reaſons which declare that kind of humor to be in the Brain and nervous ſtock, and to abound in their whole paſſages. For unleſs the animal Spirits, continually flowing out, ſhould be founded in ſuch a Latex, which is their Vehicle, they would not be contiguous or joyned, nor able to continue and knit together the *Syſtaſis* of the ſenſitive Soul. For if *Hipocrates* did obſerve long ſince, that Cramps and Convulſive motions were produced from drineſs and emptines, that perhaps might happen by this means: to wit, becauſe humor in the Nerves or Fibres being deficient, the Spirits diſtracted one from another, were ſeparated; which notwithſtanding, that they might ſtill retain their mutual embraces, and as it were folding of hands, bend the containing bodies, and very much contract, and ſo force them into Convulſions. Beſides, Wounds and Impoſtumes of the Tendous and nervous part ſeem to witneſs the diffuſion of the nervous Juyce, either of which drop forth a thin Ichor, and wholly unlike to the mere bloody Excretion: no leſs may be argued from the Ganglia and evil running Sores. In time of ſleeping the aforeſaid humor is wont to flow more plentifully into the Brain and Nerves, and to obſtruct their paſſages; and therefore yawnings and ſtretchings come frequently upon thoſe awaking, that its reliques might be ſhook off. Laſtly, we might readily ſhew, that from the depravation of

the

the nervous humor, Melancholy, Madneſs, and ſome wonderful Convulſive diſtempers proceed. But it may be objected, that there is no ſuch kind of humor, becauſe the Nerves being cut aſunder, it is not perceived to flow out; and that the Nerves being alſo bound, they do not ſwell above the Ligature, as Arteries and Veins. But it may be anſwered, That the liquor flowing in the nervous ſtock, is very ſubtil and ſpirituous, and which, by any ſtriving or wrinkling up of thoſe parts, when they are roughly handled, may eaſily evaporate and be blown away or diſperſed unperceivably. Then further, tis obſerved in the Whelps of ſome Animals newly litter'd, who have as yet that juyce viſcous, and not eaſily to be diſperſed, and that have their Nerves greater, if they be bound hard together with cords they will ſwell above the Ligature.

Therefore ſeeing it appears, that a certain Humor doth creep through the blind Pipes and paſſages of the Head and of the Appendix, both medullar and nervous, it behoves us next of all to inquire from whence that comes thither, and whither it tends; and laſtly, of what kind of nature and uſe it is. Concerning theſe firſt it appears, from what hath been ſaid, that the aforeſaid Latex, ſerving for a Vehicle of the animal Spirits, is perpetually inſtilled, together with them, from the blood watering the exterior confines of the Brain and Cerebel, which from thence, paſſing through the medullar Trunk, is afterwards, with a gentle ſpring, poured through the whole frame of the nervous Syſtem; ſo that the firſt fountains of the nervous humor are in the Brain and Cerebel. But further, to this Juyce conveying the forces of the animal Spirits, and ſupplied only from the Head, there joyns a certain other humor, as it were auxiliar in the whole paſſage, and reſtores and refreſhes it otherwiſe about to grow deficient.

We think that theſe kind of ſupplements and ſubſidies, which happen to come from elſewhere to the nervous Juyce flowing from the Head, are received and addmitted inwardly from the ſides and extremities of the medullar and nervous Syſtem. We have already ſhewed that an humor, as it were ſecondary, is inſtilled from the blood watering theſe parts in its whole paſſage; becauſe the Arteries follow out only the medullar Trunk, but alſo the greater Trunks of the Nerves in many places, and inſert into them ſanguiferous ſhoots. Beſides, foraſmuch as the animal Spirits flowing within the nervous ſtock for the performing of ſenſe and motion, tend to and fro, and ſo bear a double aſpect; it is probable alſo, that the liquor watering the Nerves, as it moſt commonly tends forward, ſo ſometimes backward; and ſo that the extremities of the Nerves, implanted in ſome parts, imbibe from them the humor, at leaſt ſome Effluvia's, with which they are ſatisfied, and oftentimes transfer them into the Brain it ſelf. Certainly there is no doubt, that the Fibres and nervous Filaments or threads which cover the Senſory of taſte, and the *Viſcera* ſerving for Concoction, do immediately receive ſome taſtes of the taken in food, from which ſupplies are carried to the Brain it ſelf in great hunger and faintneſs of Spirits. Becauſe if at any time the Spirits inhabiting it, being exhauſted very much with heavy and long labour, begin to fail, a moſt ſwift refection is performed, Pectorals or Cordials being ſcarcely ſwallowed, and long indeed before the alible Juyce can be able to reach to the border of the Brain by the paſſage of the blood. Moreover it is moſt likely, that not only the benign Effluvia's of the aliment are received by the extremities of the Nerves ending about the *Viſcera*; but alſo by this way, that oftentimes an infeſtous matter, and in a manner malignant, is communicated by the Nerves and their paſſages to the Head. But indeed the preternatural Juyces heaped up about the Hypochondria, the Spleen, Womb, and other Bowels emit vaporous little bodies; which not only infect the bloody maſs, and diſtemper the Head by that means, but they climb to the Brain more immediately by the paſſage of the Nerves, and ſtrike it with an heavy ill. For from hence in part it comes, that Hypochondriacks and Hyſterical people are ſo cruelly puniſhed through the Symptoms ſtirred up in the Brain and nervous ſtock for the faults of the lower Bowels; hence it is, that little Pills of Opium, being ſcarcely diſſolved in the Stomach, cauſe a Torpor or heavineſs. But here is no place to diſcourſe more largely of theſe. It behoves us to conſider what remains, the Springs of the nervous Juyce, the Auxiliaries but now detected, and its Virtues and influences.

Concerning the nervous Liquor we ſhall inquire what that doth in its paſſage, to wit, whilſt it flows within the Marrows or middle of the Brain and Cerebel, the medullar Trunk and the bodies themſelves of the Nerves: ſecondly, then for what uſes it ſerves, when being ſliden from the ends of the Nerves, it is ſpread abroad on the ſecondary parts of the nervous Syſtem.

1. As to the firſt, whilſt that of the nervous Liquor paſſes through the Head, and either of its Appendix, its chief office ſeems to be for a Vehicle of the animal Spirits, which indeed it carries along with its diffuſion, and contains them under the ſame *Syſtaſis*. Yea, this Latex ſhews various Schemes of the Spirits for the performing of ſenſe and motion; even as the humid Particles of the Air paſs through the Optick Configurations of the Rays of Light. Alſo moreover, the nutrition of the aforeſaid part and accretion or growth into a bulk, depends in ſome meaſure upon the nervous Juyce watering the ſame, as ſhall be ſhewed by and by.

2. But the greateſt queſtion is concerning this Liquor being diffuſed beyond the ends of the Nerves upon the ſecondary parts of the nervous Syſtem, and in the paſſages of them on the whole Body; to wit, whether ſuch a Juyce be nouriſhing of all the ſolid parts, or of ſome of them by themſelves, as Authors variouſly think; or to what other office it is deſtinated.

Concerning

Concerning theſe it. firſt appears, that the Brain and Nerves, with the Juyce flowing out of them, contribute matter, or at leaſt ſome influence to the work of nutrition; the which if it ſhould chance to fail (a ſign of which defect is, if the animal Faculty falters in part) the nouriſhment there is wont preſently to be hindred or perverted. This is plainly ſeen in the Palſie, excited from an evident cauſe, without any previous Dyſcraſie of the blood, where ſuddenly an Atrophy follows the privation of motion or ſenſe, or of both together. Further, in the Scurvy, where the taint hath corrupted the nervous Juyce, when the ſick begin to be afflicted with the Vertego and ſwimming of the Head, and with wandring pains, Convulſions, and a frequent looſning of the Members, the fleſh falls preſently away, as in a Conſumption, and without any fault of the Lungs, the ſick wither away, as if diſtempered with a Phthiſis. It is a vulgar obſervation, That from the immoderate uſe of *Venus*, alſo from an inverate Gonorrhœa, from Strumous or running Ulcers, and other Impoſtumes, by which much of the nervous Juyce is waſted, a leanneſs or waſting of the whole Body is produced. Certainly, if I be not deceived, there are ſome Atrophies, yea, and ſorts of breakings out, which ſeem to depend wholly upon the defect or the evil diſpenſation of the nervous Juyce, when the blood, as to its quantity and diſpoſition, is not much in fault. Laſtly, the conſideration of ſome Diſeaſes and Symptoms ſo plainly confirms the diffuſion of the nervous Liquor and its great influence on all the parts, that there is even left no room for doubting.

Alſo no leſs doth the curing of ſome Diſeaſes and the uſe of Remedies confirm the ſame. For from hence a reaſon is taken, wherefore Cephalick Plaſters oftentimes yield ſuch ſignal help in the *Phthiſis*; not becauſe they ſtay the *Catarrh* of the Serum falling down on the Lungs, (as the common people think) but becauſe by corroborating the Brain they reſtore the diſpoſition of the nervous Juyce, before vitiated. For this cauſe it is, that ſome diſeaſes being ſtirred up by the fault of the nervous Liquor, of which ſort among others are Cancrous and Strumous Ulcers, or ſuch as come of the Kings-Evil, are hardeſt of all to be cured; becauſe the morbid tincture of the Brain, and of the *Latex* watering it (whether it be innate or acquired) is not eaſily mended: yet ſometimes when the root of the diſeaſe, lurking in the Brain or nervous ſtock, is taken away by the help of Nature it ſelf, or by Chance, by the uſe of ſome remedy; preſently the Symptoms of other parts, though neglected in the whole, vaniſh, not without the ſuſpicion of a miracle. But how much the alteration of the Brain ſerves for the curing of ſome moſt grievous diſeaſes, ſome inſtances taken from the Farriers Art will clearly ſhew.

For when many Medicines and Methods of Adminiſtrations are wont to be tryed in vain for the curing the ſtinking diſeaſe in Horſes, commonly called the *Farcy* (which *Helmontius* aſſerts to be like the French Pox, and the author of its Contagion) the moſt certain means of curing (which I have very often known to be applied with good ſucceſs) conſiſts in this; that ſome ſharp Medicines, of which ſort are Hearts-eaſe, Water-Pepper, Ranunculus or Crowfoot, and the like, which very much abound in volatile Salt, being bruiſed into a maſs, and put into the Ears of the diſeaſed Horſe, and kept there for twenty four hours: it is ſcarce credible by what means all the Ulcers are preſently dryed up, and the diſeaſe healed, as it were by Inchantment, is quickly profligated in the whole. For ſince this Application is made far from the affected parts, without any alteration of the bowels or the blood, it ſhould be ſo healed at a diſtance; certainly the cauſe of ſuch an Energy muſt only be, that by this kind of Medicine the Dyſcraſie or evil diſpoſition of the Brain and nervous Juyce is taken away, and ſo the firſt root of the ſickneſs being cut off, the ſhoots and fruits preſently wither. It were worth our labour to try ſuch kind of Experiments that alſo in our Medicines. Yea it may be well ſuſpected, that ſuch a way ought to be ordered for the common Cure of the Kings-Evil. Among our Country-men, as delivered from our Anceſtors, it is thought the ſeventh Son, or he that is born the ſeventh one after another in a continued ſeries, can cure this diſeaſe by ſtroking it only with his hand; and truly I have known many, whom no Medicines could help, to have been cured in a ſhort time only by that remedy. Few doubt but that this diſeaſe is wont to be cured often by the Touch of our King. The reaſon of ſuch an effect (if it be merely natural) ought to be aſſigned not to any other thing than that in the ſick (eſpecially thoſe of ripe age) the Phantaſie and ſtrong Faith of the hoped for Cure induces that alteration, or rather ſtrengthning to the Brain, whereby the morbid diſpoſition radicated in it is profligated. But I ſhall return from whence I am digreſſed, to inquire what the nervous Juyce contributes to nutrition.

2. I ſay therefore ſecondly, although nutrition depends in ſome meaſure upon the influence of the nervous Juyce, yet it is highly improbable, that all the ſeveral parts of the whole Body ſhould be nouriſhed only by this proviſion. For beſides that this, were to impoſe upon the Government of the Soul it ſelf, and its primary Organs, the cooking office of nutrition wholly unworthy the excellency and dignity of thoſe parts; it ſeems alſo that the nervous Liquor ſhould be all together unfit for the adminiſtring to this Province: becauſe when oftentimes immenſe expenſes are made of the aliment to be aſſimilated into the ſubſtance of the ſolid parts, eſpecially by immoderate ſweat, alſo by continual labour and exerciſe, which Country-men and Labourers daily uſe, it is not poſſible that ſuch loſſes ſhould be repaired only by the nouriſhment ſupplied, or ſent through the ſmall paſſages of the Nerves.

When I had long and ſeriouſly conſidered with my ſelf concerning this thing, what I at length thought, I ſhall tell you freely, and without any covering, or making any reflection, or blaming the Opinions of others. It ſeems firſt, that the nouriſhing matter of the whole Body is diſtributed into all parts from the blood through the Arteries; yet it may lawfully be thought, that the converſion of this matter into nutriment, and the aſſimulation of it into the ſubſtance of the part to be nouriſhed, is performed by the

the influence and help of the nervous Juyce, as it were of a certain ſpirituous Ferment. As to the firſt: we have already noted, that the ſanguiferous Veſſels do not only follow almoſt every where the Muſcles and Bowels, but alſo the Head and its Appendix, yea the Membranes, Bones, and Nerves themſelves, and affix to them all thick ſhoots, as ſo many little chanels, for the receiving the nouriſhment. Moreover, as there is a purple craſſament or thick ſubſtance in the blood, whoſe ſubſtance ſtuffs and nouriſhes the Pores of the Parenchyma of the Muſcles; ſo there is a whitiſh Gelly, by which the Membranes and the whiter parts ſeem to increaſe. Beſides it may be obſerved, that the blood it ſelf increaſing, contains in it ſelf fibres and ſmall threads, ſuch as are interwoven in the Muſcles and nervous parts; and if the ſame ſtand long in any Veſſel, it is preſently coagulated into longiſh, white, and hard cruſts or bits, whoſe ſubſtance is plainly fleſhy; ſo that the blood produces fleſh of it ſelf, though the ſame be rude and unformed: wherefore the configuration and the apt diſpoſition of the nouriſhingmatter, ſupplied from it, depends on the coming and Energy of the nervous Juyce: but after what manner this is done, we ſhall endeavour now to ſhew.

After the web or ſtuff of all the parts is laid, it is required then that they be both drawn forth in due proportion, and grow in ſubſtance, and alſo that the little ſpaces which are left by reaſon of the Effluvia's perpetually falling off, may be continually filled with the nouriſhing ſubſtance caſt in. In theſe two things the buſineſs of nutrition chiefly conſiſts; for the performing of either of which the blood affords matter, and reaches it forth (as was ſaid) in the circulating to the ſeveral parts of the concrete, and as it were ſtands at the doors of the part to be nouriſhed: yet, that this matter may be rightly diſpoſed, and its particles, to wit, the thick and thin, ſaline and ſulphureous, and others of a ſeveral nature, ſeparated one from another, may be imployed with ſome choice to the deſtinated uſes, there ſeems need of a certain directing faculty, and as it were plaſtick virtue, got ſomewhere elſe than from the blood it ſelf. For indeed the blood being deſtitute of animal Spirits, is unfit for the performing theſe offices. Wherefore, for that it appears there doth lye hid in the nervous ſtock, a certain juyce, and the ſame being gifted with animal Spirits to be diffuſed to all parts, how can we ſuppoſe leſs but that this ſubtil and ſpirituous Liquor, every where meeting with the arterious which is duller and thicker, actuates and inſpires it, and as it were ordains it for the performing the deſigned work of nutrition? eſpecially when it plainly appears, that by reaſon of the defect or depravation of this nervous Juyce, nutrition is always fruſtrated or perverted.

Therefore it may be lawful, in the difficult Controverſie concerning the Matter and Method of Cure, to propoſe this our Hypotheſis, though it be a Paradox and very abſtruſe; to wit, that the nervous Juyce (which we have ſaid was like the male ſeed) is poured out with the nutritious humor copiouſly ſuggeſted from the Arteries, as it were the genitive or ſeed of another Sex, every where upon all the parts; and that this former, being indued with active Elements, imbues the more thick matter, as with a certain Ferment, and impregnates it with animal Spirit; and when it ſo makes it, with a mutual entring in or coming together, to be diſſolved and to go into parts, its particles being extricated one from the other (the Spirit infuſed helping) they are put upon bodies of the ſame meaſure with themſelves, and are aſſimilated into their ſubſtances. In the mean time, becauſe the animal Spirits are poured out in great plenty with the nervous Juyce, thoſe which are at leiſure from the work of nutrition, or remain after that is finiſhed, turn aſide every where into the Fibres, as into proper dwelling-houſes, and there being ready for the offices of ſenſe and motion, ſtay; which offices indeed, that thoſe Spirits the Inhabitants of the Fibers, may the better perform, they acquire from the blood watering the Muſcles, certain auxiliary forces, wherefore they being endued with a certain elaſtick force, are apt to be highly rarified and as it were exploded.

But indeed we ſuppoſe, that as the nervous Liquor, being turgid with animal Spirit, cauſes the arterious humor to become nutritious; ſo in compenſation of this the animal Spirits remaining of the work of nutrition, and every where diſpoſed within the Fibres, receive from the arterious blood a mixture or certain Copula; by whoſe help and cooperation the ſame Spirits exert or put forth much more ſtrongly their locomotive force. For it ſeems that little ſulphureous bodies are added to the ſpirituous-ſaline particles from the watering blood; and ſo when the animal Spirits are furniſhed with this Copula, they being ſtirred up into motion, ſhake off the borrowed particles, which being ſtruck with a certain force, like the exploſion of Gun-powder, ſuddenly intumifie the Muſcles, and ſo by contracting them very much, they cauſe a vehement motive endeavour. We ſhall have an occaſion of diſcourſing more at large of this, when we treat of the Motion of the Muſcles.

Yet in the mean time, we ſhall take notice, that the Muſcles of the whole Body, as to their motion, have a certain Analogy with the motion of the Heart. For indeed the animal Spirits in the Heart, flowing within the fibres and nervous threads, (with which this part is much beſet) receive plentifully ſulphureous little bodies from the inflowing blood diſtending the ſides of either boſom, which whilſt the ſame Spirits, being filled to a fulneſs, ſhake off and as it were explode, a *Syſtole* of the whole Heart (its ſides being carried with a certain force inwards) is brought in or cauſed, whereby the blood, from either ſide the boſom is caſt out as as it were by the impulſe of a Spring or Bolt. Truly, unleſs the Spirits inhabiting the Heart, ſhould receive food and matter of exploſion from the blood it ſelf, their ſtock, ſupplied or ſent by the paſſage of the few and ſmall Nerves, would not ſuffice for the performing of the undiſcontinued motion. A ſign of this is, that from a defect or depravation of the blood, as well as of the animal Spirits,

Spirits, the motion alſo of the Heart is defective or diminiſhed. And not much unlike in the Muſcles, as in the Heart, is the buſineſs performed; the Spirits inhabiting their Fibres, receive a ſulphureous Copula and apt for exploſion, from the blood there more plentifully flowing than about the Membranes, with which being endued, as often as they receive from the Nerve as it were the fiery inkindling or the match, the inſtinct of the motion to be performed, they being excited, and ſtriking off their Copula, very much inflate or blow up the Muſcle, and intumifie it for performing or compaſſing the motive endeavour. Nor is it much to purpoſe, or makes any great difference, that the motion of the Heart, ſtirred up by a perpetual inſtinct, is found always neceſſary; but the Muſcles the moſt of them only occaſionally and at the command of the Animal, do put forth their motive power; for the *Diaphragma* and ſome Muſcles, dedicated to Reſpiration, are urged with a perpetual *Syſtole* and *Diaſtole*, as well as the Heart it ſelf.

From the aforeſaid Hypotheſis concerning the offices and uſes of the nervous and arterious Juyce, Arguments that otherwiſe determine the work of Nutrition, may be eaſily anſwered. For that the blood is ſaid rather to prey upon the ſolid parts than to repleniſh them, that ought to be attributed to the Diſeaſe and Dyſcraſie of it, and not to it ſimply: becauſe ſometimes the blood is accuſed, for that it too much ſtuffs the ſolid parts; to wit, foraſmuch as its maſs being wateriſh and weak, it lays aſide the alible Juyce (which not being truly cook'd, is ſtill crude and vicious) with very great plenty about the habit of the Body, and ſo induces an *Anaſarcha*. In the mean time it ought to be granted, That as it is the blood that is evil which heaps up too much vicious nutriment; ſo it is the ſame, which being well and right, doth laudably perform the office of Nutrition.

But that it is argued, That the nervous is rather the nouriſhing Juyce, becauſe by reaſon of its defect, depravation or too prodigal expence, the acts of nutrition are wont to be hindred or perverted; it is eaſie to reply to this, That the impediments of the nervous Juyce, being made vicious, reſpect the form of nouriſhment, and not the matter of it: to wit, it ſometimes happens, that the blood diſpenſes the alible matter in due plenty and diſpoſition; which notwithſtanding, by the fault of the nervous Juyce, is not rightly aſſimilated. When an impotency of motion comes upon a too great diſtenſion of the Muſcle or Tendon with pain, ſhortly nutrition being hindred, a Jelly grows about the diſtempered part: which notwithſtanding drops not out of the Nerve (as is commonly ſaid) but the glutinous humor being poured out of the Arteries for aliment, for that it cannot be received by the hurt part, is gathered together there: nor is it to be thought, that Tumors, or Strumous Ulcers or the running Sores of the Evil do contain or pour out only a nervous humor, ſince the matter of either is for the moſt part bloody, which by reaſon of the evil Ferment of the nervous Juyce, puts on a ſtrange form, and that diverſly degenerous.

This ſuppoſition of the twofold Humor, for the matter and form of nouriſhment, is taken to be of egregious uſe for the ſolving of the moſt difficult *Phenomena*, which are met with about the Diſtempers of the Brain and nervous Juyce: yea that Pathology, ſeriouſly conſidered, ſeems to infer as a certain neceſſary conſequence, that a twofold Juyce is neceſſary for the work of nutrition; as ſome other time perhaps we may ſhew. In the mean time, leaving this Speculation, we ſhall proceed to the remaining Task of our *Anatomy*, to wit, the *Neurologie* or of the *Nerves* in particular.

THE Deſcription and Uſe OF THE NERVES.

CHAP. XXI.

The firſt four Pair of Nerves ariſing within the Skull are deſcribed.

THE diviſion or diſtinction of the Nerves, by reaſon of their various reſpects, is wont to be manifold: to wit, as they are either ſoft or hard, ſingular or numerous in their beginnings; or that they ſerve either to the faculty of Senſe or Motion, or to both together. But they are commonly diſtinguiſhed, That ſome Nerves ariſing within the Skull, proceed from the *oblong Marrow*; and others going out of the joynts of the *Vertebra*, are derived from the ſpinal *Marrow*. But beſides theſe, another manner of differencing them ſeems beſt to us; to wit, That ſome Nerves, as it were Clients and Servants of the Brain, perform only ſpontaneous Acts, and others, Miniſters and Servants of the Cerebel, are imployed only about the exerciſes of the Involuntary Function. There will be no need to aſſign different Eſſences or Conſtitutions of Nerves according to theſe ſeveral differences: but rather that there be inſtituted a particular Cenſe or Muſter of them, and following the order of Nature, that we eſpecially unfold every one of them in the ſeries in which they are diſpoſed in the animal Body.

Among the Nerves ariſing from the Skull, the ſmelling Nerves, or thoſe which are commonly called the Mammillary Proceſſes, lead the way; for that they have their riſe before all the reſt, and are ſtretched out forward beyond the Brain it ſelf. Theſe Nerves go out of the ſhanks of the oblong Marrow within the chamfered bodies and chambers of the Optick Nerves; and being endued with a manifeſt cavity, open into the firſt Ventricle of the Brain on either ſide behind the ſame chamfered bodies; ſo that the humidity flowing between the folding of the Brain, is carried through theſe chanels into the mammillary Proceſſes; whether they go farther forward, ſhall be anon inquired into: Becauſe theſe Nerves being broad and large, ariſing near the chamfered bodies, and from thence ſtretched forward under the Baſis of the Brain, their bulk is increaſed by degrees till they go into the round Proceſſes like Paps, by which either boſom of the Cribrous or Sieve-like Bone is beſmeared. Within the Socket of this Bone theſe Nerves, as yet ſoft and tender, obtain Coats of the *Dura Mater*; with which being divided into many fibres and filaments, and paſſing through the holes of the Sieve-like Bone, they go out of the Skull: from whence being dilated or carried forward into the caverns of the Noſtrils, and diſtributed on every ſide, they are inſerted into the Membrane beſpreading thoſe Labyrinths.

If we enquire into the nature and uſe of theſe parts, without doubt the mammillary Proceſſes and their medullar roots, with the fibres and ſmall threads hanging to the ſame, are truly Nerves, and ſerve properly for the very Organ of the Smell. Seeing theſe conduce to the ſenſe only without any local motion, therefore (even as the other hearing Nerve) whilſt they are within the Skull, they are plainly medullar and ſoft; whereby the Animal Spirits more eaſily moved within the more tender ſubſtance of the Nerves,

Nerves might convey more readily and accurately to the common Sensory the Ideas or Forms of the sensible Species: But because the Effluvi's or odorous breaths to be received by the naked Organ, carry oftentimes with them sharp and pricking Particles hurtful to the Brain and Nerves; therefore in the first course these Nerves being about to go out of the Skull, borrow Coats from the *Dura Mater*, which serve for Armour. Further, as these breaths (lest they should strike more sharply by rushing impetuously on the Sensory) being admitted only by little and little, and by small bands, ought to be brought through divers narrow turnings and windings of the Nostrils; therefore that these Nerves may the better receive the effluvia's flowing within the several dens, they are so divided into very many fibres and small threads or filaments, that there may be no passage of the Nostrils to which at least some of them are not destinated. And after this manner, although the exhalations, as it were torn into little Clouds, are received by the nervous filaments, and so care is sufficiently taken, that they being more thickly elevated, may not overwhelm or obscure the Sensory; yet lest any thing sharp and troublesome should be carried with them to the Brain, the cribrous bone is set before the doors as an obstacle, through whose little holes being strained, they may put off all sharpness. And lastly, they being carried through the softer Nerve, as it were another Medium, and so broken again, they at length being soft and gentle enough, are staid at the first Sensory.

But that these Nerves are noted through the whole with an open hollowness within the Skull, the reason seems to be, that the watry humor trilling out of the foldings of the Brain, and being derived into those chanels, might beat back and temper the impressions of the odours, when too sharp and fiery; for as the humors included in the Eye, variously refract the visible Species, whereby it passing at last through the Optick Nerve without any force, slides pleasantly to the common Sensory; so it is not improbable, that the water contained within these passages of the Nerves, does in like manner sweeten the species of the odours, and prepare them in some measure for the Sensory. Wherefore it is observed, that Cattle and Beasts which are fed with herbage, have the mammillary Processes exceeding large and always full of water; to wit, lest the odours of the herbs continually attracted by them (unless their force should be blunted after the aforesaid manner) might hurt or overthrow their more weak brain. Besides, it is very likely that this watry juyce falling down from the infolding of the Brain, doth not only flow into the open chanels of the Nerves and the mammillary Processes, but also doth pass through by the passage of the fibres and filaments the holes of the Sieve-like bone, and doth wet and continually moisten the cavities of the Nostrils, apt to be dryed or torrified too much by the Air thither attracted, and by the breath continually blown out. For it clearly appears, as we have elsewhere shewn, that the serous humors creep through the blind passages of the Nerves and Fibres, and by them wander from place to place. Yea it may be thought, that not only water, sufficient for the watering the Nostrils, doth by this way sweat through; but also whensoever the serous heap is gathered together in the Ventricles of the Brain, its superfluities or the excrementitious humor doth very often pass through the cribrous Bone by the passage of the Fibres, and is sent out. But we have in another place discoursed more largely of this.

The smelling Nerves, which have within the Skull their mammillary Processes depending on them, are much greater in an Ox, Goat, and in Cattle, and such like beasts that live on herbage, than in flesh-eating Animals; to wit, because in those there seems to be more need of the sense of smelling to be more exquisite for the knowing the virtues of the manifold herbs. Also these Nerves are larger in all Brutes than in Man: the reason of which is, because they discern things only by the sense, and especially their food by the smell; but Man learns many things by education or nurture and discourse, and is rather led by the taste and sight, than by the smell in chusing his aliments. These Nerves in Birds, as also in Fishes, are conspicuous enough; for either of these, even as four-footed beasts seek out and chuse their food by the help or knowledge of the smell.

As to the Fibres and Filaments or little strings stretching out from the more soft Nerves through the holes of the Sieve-like Bone into the caverns of the Nose, these are found in all Creatures who have the mammillary Processes: so that it is not to be doubted, but that these Processes, with this Appendix and its medullary origine, is the Organ of the Smell. And what more confirms this thing, these filaments or little strings are far more, and more remarkable in hunting Hounds than in any other Animal whatsoever. But besides these Nervulets drawn through the holes of the Sieve-like Bone into the Nostrils, two branches also are sent hither from the fifth pair, and distributed into both the Nostrils. The reason of this seems to be, because though the Nerves but now described, or of the first Conjugation, are properly smelling Nerves, and effect by themselves the sense of Smelling; yet these are assisted or joyned with other Nerves, also by those sent from the fifth pair, because the Organ of the Smell ought to have a consent with all other parts, which those subsidiary Nerves, by reason of the manifold branching out of the fifth pair, are wont to perform. It chiefly appears, that there is a certain nearness or strict affinity between the taste and the smell: and the cause of this consists, in that out of the same Trunk of the fifth pair certain Nerves are sent to the Palate, and others to the Nostrils. Concerning the reason of that wonderful consent which the Nostrils have with the *Præcordia* in sneezing, also wherefore that light titillation stirs up a Cough, shall be spoken of hereafter, when we come to unfold the fifth pair and the intercostal Nerves. But in the mean time we shall take notice, that although many Nerves belong to the Organ of Smelling, yet that sense is properly performed by the Fibres interwoven in the inward Coat of the Nostrils: for those Fibres being struck by the sensible object, move and contract themselves variously according to the Idea of the

impreſſion; which Affection of them being carried by the paſſage of the *Nerves* to the Head, foraſmuch as it is there ſtaid by the common Senſory, cauſes the perception of the ſenſe. Thoſe ſenſible Fibres are diverſly figured in ſeveral Animals; which is the reaſon, why odorous things do not alike affect all Animals. For what things by a mans noſtrils, as endued with too ſharp and pricking Effluvia's, are eſteemed highly naught and ſtinking, as eſpecially are dung and putrid fleſh; the ſame are to Dogs, whoſe Organ of Smelling is made or conſiſts of more robuſt or ſtrong Fibres, and proportionate to thoſe Effluvia's, as very grateful and choſen for food.

The ſecond Conjugation are the Optick or ſeeing Nerves: concerning which we have ſhewn already, in the *Anatomy of the Brain*, after what manner they ariſe from behind the chamfered bodies out of the ſecond ſection of the medullar ſhanks (which *Galen* calls the *Chamber of the Optick Nerve*) and deſcending from thence with a certain compaſs are united, and being again ſeparated and carried into the Ball of the Eyes, conſtitute with diffuſed Fibres the hard Coat. Moreover, in thoſe Obſervations we did but now take notice, that the Trunk of this *Nerve* growing a little hard without the Skull, was as it were a little bundle of very many Fibres or ſmall ſtrings growing together into one, and of produced Parallels, as it ſhould ſeem for that end, that the animal Spirits, flowing in the whole *Nerve*, might be moved in ſo many lines or direct rays; to wit, whereby they may carry the viſible Species, ſufficiently refracted in the Eye, thence to the common Senſory by a direct beam, and not intorted or rolled about.

As often as in the diſtempers of the Eyes blackiſh pricks or concatenated pieces of any thing ſeem to be rolled before the Eyes, it is likely that this apparition is ſo made, becauſe certain filaments or ſmall ſtrings of the *Optick Nerve* are ſhut up, which when the light cannot paſs through rightly, as through the reſt, ſo many as it were ſhadowy ſpaces appear in the middle of the clearneſs. Theſe Nerves, becauſe they only ſerve for the ſenſe, are therefore more ſoft within the Skull: but becauſe there may be need perhaps, that the Trunk of this *Nerve* ought to be ſometimes dilated or ſpread abroad, ſometimes bound cloſe together or contracted according to the divers appearance and incourſe of the objects; therefore very many Fibres, being ſent out from the motory or moving *Nerves* of the Eyes, do every where compaſs and bind it about, and entring with it into the Ball of the Eye, are inſerted partly near the root of the Optick *Nerve*, and partly penetrate more deeply the Sclerotick or hard Coat it ſelf.

Further, the *Optick Nerves* are not only bound or environed with nervous Fibres ſent from the third pair, but (as we have ſhewn above) with ſanguiferous Veſſels in their whole proceſs. The office of which certainly is, both that there might be every where about the greater Trunk of this *Nerve* as it were a continual heat or ſufficient fire-place; alſo perhaps, that the food of the bloody humor might be ſupplied to the Spirits, living there within the Trunks of the *Nerves*, far from the fountain, as is wont to be in other places.

Concerning the Fabrick of the Eye it ſelf, and manner of ſeeing, alſo concerning the whole dioptrick proviſion, here ſeems a fit opportunity of diſcourſing: but this were to digreſs too far from our purpoſe, to wit, the mere or naked Doctrine of the *Nerves*; and I may the better paſs by this addition, becauſe this Province hath been ſufficiently and accurately adorned by others. In the mean time we ſhall take notice, that as in the ſmelling, ſo alſo in ſeeing, the ſenſe is performed, not ſo much by the help of the nerve, as of the fibres, which are interwoven with the organ: to wit, the little fibres in the Membranes of the Eyes, and eſpecially thoſe inſerted into the Sclerotick Coat, and diſpoſed after the manner of a Net, do receive the impreſſion of the viſible Species, and by repreſenting the image of the thing, ſo as it is offered without, cauſes ſight. But it is the office of the Nerve it ſelf to tranſmit inwardly, as it were by the paſſage of the Optick Pipe, that image or ſenſible Species, and to carry it to the common Senſory.

The third Conjugation of Nerves are the moving *Nerves* of the Eyes, which ariſe in the Baſis of the medullar Stem behind the Tunnel; from whence going forwards nigh the pair of ſeeing Nerves, and going out of the Skull with the other *Nerves* deſtinated to the Eye, they are carried towards the Globe of the Eye; where being preſently divided into many branches, they provide it with moving Muſcles; but with various difference in divers living Creatures. For in an Ox, who hath got a larger Eye, the moving Nerve of the Eye imparts a branch to every one of the ſix common Muſcles; and beſides, from the Nerves of the fourth, fifth and ſixth pair certain branches are diſtributed to ſome of the ſame Muſcles: ſo that, as often as any Animal intends or applies the ſenſe for the perceiving of this or that object, theſe Nerves turn about the Eye, and compoſe it at their pleaſure for the ſpontaneous beholding of the ſame. Beſides we take notice, that the Eyes do get a diverſe kind of involuntary motion; becauſe in Fear, Shame, Anger, Sadneſs, yea and in all Affections of the Head and Heart, whether we will or no, the Eyes are reſpectively figured. Wherefore 'tis highly probable, that theſe kind of pathetick motions of the Eyes, whereof the living Creature is ſcarce knowing, are performed by the help of the other nerves, to wit, of thoſe coming from the fourth, fifth, and ſixth pair: and that more manifeſtly appears, becauſe the ſame nerves which lend their branches to the Eye, take their origines from the Cerebel, the office of which we have often ſhewn to be, to diſpenſe the Spirits for the exerciſe of the involuntary Function.

But concerning theſe Nerves of the third pair, which are properly called the Moving nerves of the Eyes, we obſerve, that in Man, a Dog, and in ſome other living Creatures they are found to be ſomewhat otherwiſe than in an Ox: for either nerve in theſe, as in the reſt, is carried out of the Skull, divided into four branches, three of which are carried from thence into three ſtraight diſtinct Muſcles, to wit, one

lifting

lifting up, the other bringing together, the third pressing close the Eye; the other branch of it goes forwards further with a single trunk, and is implanted in the middle of the Muscle going about the Eye, turning obliquely to the inward corner downwards. From these it appears, that these Muscles, to which this nerve belongs in all, are sufficient almost of themselves to perform most spontaneous motions of the Eye: but where the aforesaid nerve is divided into four shoots, it constitutes a small and round infolding, out of which many small shoots creep through, and variously compass about the trunk of the Optick nerve; for what use it is so made, we have already intimated.

The fourth Conjugation of Nerves (which we call rightly the Fourth by order and succession, although it is accounted the eighth and last by *Fallopius*) hath a diverse origine from all the rest. For whereas most of the others proceed from the foot or sides of the oblong Marrow, this hath its root in the top of it behind the round Protuberances, called *Nates* and *Testes*: from whence, bending more forward nigh the sides of the oblong Marrow, it is presently hid under the *Dura Mater*: under which going along for some space, and passing through the Skull at the same hole with the rest destinated to the Eye, it is bestowed with a single trunk, not communicating with any of the other *Nerves*, wholly on the Muscle called the Trochlean Muscle. Above we called these *Nerves* the Pathetick *Nerves* of the Eyes: for although some besides may deserve this name, (as shall be shewn by and by) yet 'tis most likely, that the proper office of these is to move the Eyes pathetically, according to the force of the Passions and instinct of Nature, delivered and remanded from the Brain to the Cerebel, and so on the contrary, from this to that through the *Nates* and *Testes*, and their medullar Processes. For, as we have shewn, that by the diverse impulse and waving of the animal spirits dwelling in this by-path, there are instituted certain mutual commerces between the Brain and the *Præcordia*, (the Cerebel mediating between either) it will be of necessity, that these *Nerves*, rooted in the middle way, should be struck by every tending downwards or remove of the Spirits, going this way or that way, and so the motions of the Eyes to follow the affections of those parts. All perfect Animals are furnished with these nerves: and in truth, as none of them but are obnoxious to Anger, Love, Hatred, and other Affections, so every little Creature shew these by the mere aspect and by the gesture it self of the Eyes. We see sometimes the greater Pike gaping for his prey first of all to roll about his eyes, and to look sour; then with a swift shooting out of his body to invade the lesser fry of fish.

CHAP. XXII.

The fifth, sixth, and seventh Pair of Nerves are unfolded.

OF the aforesaid four Pair of Nerves, the two former seem chiefly to serve for the Sense only, but the two latter for Motion; and every single *Nerve* of them destinated to a peculiar Province: but this which follows next, to wit, the fifth Conjugation of Nerves serves for the exercise of either Faculty, to wit, both of Sense and Motion; nor is its Province so strictly bounded, that it should belong only to one member, for it is distributed to the Eyes, Nose and Palate, and the rest of the parts of the Face, and besides, helps in its part in some sort the offices and actions of the *Præcordia* and almost of all the *Viscera*.

This pair (which by the Ancients was accounted the third, by us the fifth pair, and that by right of order or position) below the former nerves, proceeds with a broad and large trunk from the sides of the annular Protuberance or Process sent out from the Cerebel. It consists of very many Fibres gathered together, some of which are soft, others hard; so that the great trunk of it near its beginning, is nothing else than a little bundle of very many nerves, some of which are bestowed on these parts, and others on other parts, and in some they perform the offices of motion, in others of sense. But that so many nerves being destinated to so many several members, and remote one from another, yet arising together, are collected as it were into one bundle, the reason is, that in all the parts to which those Nerves belong, a certain Sympathy and consent of actions might be conserved: to wit, the communion of those Nerves is the cause why the sight and smell move spittle and please the Palate; nor by any other means are the *Præcordia* affected, according to the various conceptions of the Brain, and transmit their affections to the several parts of the Face; from whence the aspect or countenance of the whole Animal is pathetically figured, as shall be shewed more particularly below.

In the mean time, let us deliver a short Hypotype or Figure of this *Nerve*; its trunk going out of the sides of the greater Ring, sometimes near its beginning, but oftner the *Dura Mater* being first perforated or passed through, is divided into two noted branches. The first of these tending straight downward, going out of the Skull at a proper hole, in its descent towards the lower Jaw, (to whose parts it is chiefly destinated) is divided into more branches, with which it furnishes the Temple-muscle, also the Muscles of the Face and Cheeks. Moreover, from them shoots and branches are distributed

into

into the Lips, Gums, roots of the Teeth, Jaws, Throat, the farther end of the Palate, yea and the Tongue; for this reaſon chiefly, that the Nerves going out of the lower branch of the fifth pair, might effect, beſides ſenſe, the divers offices of Taſte and Touch or Feeling, and motions of a various kind in the aforeſaid members and parts; moſt of which, as the chewing of the aliment, alſo thoſe which have reſpect to configuration or framing of the mouth and face in laughing or weeping (as we have already noted) are performed unknown to the Brain, that is involuntarily, and by the help of the Cerebel only, from which theſe Nerves are derived.

The other ſuperior, and alſo the greater branch of the fifth pair under the *Dura Mater* nigh the ſide of the Turkey Chair goes ſtraight forward for a little ſpace, and is inlarged into ſome ſhoots over againſt the pituitary Glandula to the trunk of the Carotick Artery or the wonderful Net, (where it is preſent) then it is inoculated into the Nerve of the ſixth pair, and from thence ſends back ſometimes one, ſometimes two ſhoots; which being united with another ſhoot, turned back from the Nerve of the ſixth pair, conſtitute the root or firſt trunk of the intercoſtal Nerve. Concerning this intercoſtal Nerve, which is made of the lower ramification or branching out of the Nerves of the fifth and ſixth pair, it ſhall be ſpoken of particularly hereafter.

Preſently after the branches or ſhoots reflected or bent back for the root of the intercoſtal Nerve, that greater Nerve of the fifth pair is divided into two noted branches. The leſſer and uppermoſt of theſe tending towards the globe of the Eye, and becoming again twofold, ſends forth two branches from it ſelf; one of which turning towards the inward ſide of the Bone, containing the ball or angle of the Eye, is divided into two ſhoots. The other of theſe having paſſed through the Bone nigh the mammillary Proceſſes, is carried into the noſtrils: the office of this Nerve is to keep a Sympathy and conſent of action between the Noſtrils and ſome other parts: but the other branch of this diviſion is beſtowed on the Muſcle by which Brutes wink.

The ſecond Ophthalmick branch of the fifth pair is divided into four or five ſhoots, all which going forward above the Muſcles of the Eye, and in ſome part paſſing through its Glandula's, are almoſt all loſt in the Eye-brows, unleſs that in the paſſage they ſend down two ſmall ſhoots which enter the *Sclerotick* Coat a little below the Tendons of the Muſcles, and reach to the *Uvea*, or the fourth thin Membrane that cloaths the Optick Nerve; yea and alſo ſend in the paſſage ſmall ſhoots to the Glandula's of the Eye. It ſeems that theſe Nerves of the fifth pair, being diſtributed into the Glandula's of the Eyes and Eye-brows, ſerve chiefly to the involuntary and pathetick actions of thoſe parts; the chief of which are, the languiſhing and mournful aſpect of the Eyes in weeping, and the unwilling pouring out of tears. For as the lower branching of the fifth pair, to wit, the intercoſtal nerve, provideth in man for the *Præcordia*, it eaſily happens, that from the ſad affection of theſe, the Cardiack branches of this *Nerve* being forced and wrinkled into Convulſions, the aforeſaid Ophthalmick branches alſo ſo correſpond, and by wrinkling the Eye-brows, and by compreſſing the Glandula's, produce thoſe kind of looks of the Eyes, and marks of ſorrow and grief. Further it is obſerved, that from the Ophthalmick branch of the fifth pair a certain ſhoot is ſent back higher nigh the heads of the Muſcles; which when it has paſſed through at a proper hole, the Bone containing the ball of the Eye, is carried ſtraight into the caverns of the Noſtrils. Hence, as I think, a reaſon may be given, wherefore paſſing out of a dark place into the light, at the firſt beholding of the Sun, preſently whether we will or no we ſhall ſneez; to wit, the eyes being too ſtrongly ſtruck by the object, and being ſuddenly and diſorderly moved, that they might turn themſelves aſide, the ſame affection is immediately comunicated through the aforeſaid *Nerve* to the Membrane covering the hollow caverns of the Noſtrils, which being thence contracted and wrinkled, (as it is wont by ſome ſharp thing pulling it) provokes ſneezing.

The ſecond or greater branch of the ſecond diviſion of the Nerve of the fifth pair being carried nigh the ball of the Eye, is again divided into two branches. The lower of theſe being bent downwards, cleaving into many ſhoots, is beſtowed on the Palate and upper Region of the Jaws: The other and higher branch of this ſecond diviſion ſtretching beyond the ball of the Eye, paſſes through, together with the Vein and Artery, a proper hole made in the bone of the upper Jaw; which Veſſels this *Nerve* climbs and variouſly compaſſes about with many ſhoots ſent forth; then ariſing out of the bone, it imparts little branches to the Muſcles of the Cheeks, Lips, Noſe, and to the roots of the upper Teeth. Therefore foraſmuch as this *Nerve* embraces and binds about the ſanguiferous Veſſels deſtinated to the Cheeks and the other parts of the Face; from hence a reaſon may be given, why the face is covered with bluſhing by ſhame: for the animal Spirits being diſturbed by the imagination of an unſeemly thing, by and by endeavouring as it were to hide the face, their irregularities enter this *Nerve*, ſo that the ſhoots of the ſame *Nerve*, embracing the blood-carrying Veſſels, by compreſſing and pulling the ſame, cauſe the blood to be more forced into the Cheeks and Face, and the Veins being bound hard to be there for ſome time ſtaid and detained. But foraſmuch as many ſhoots and fibres of the ſame maxillar *Nerve*, derived from the fifth pair, interweave themſelves with the fleſh and skin of the Lips, hence the reaſon is plain, why theſe parts are ſo very ſenſible, and beſides, why the mutual kiſſes of Lovers, impreſſed on the Lips, ſo eaſily irritate love and luſt by affecting both the *Præcordia* and Genitals; to wit, becauſe the lower branching of the ſame fifth pair actuates theſe parts conſtituted in the middle and lower Belly, and draws them into the like affection with the Lips. The ſame reaſon holds of Love preſently admitted by the eyes, that as the Poet ſays,

Mars *videt hanc, viſamq; cupit.*
As ſoon as *Mars* ſaw her, he deſir'd her.

We

We have but now intimated, that many ſhoots of this Nerve were deſtinated for the buſineſs of chewing; and therefore, becauſe the aliments to be taken ought to undergo not only the examination of the taſte, but alſo of the ſmell and ſight, from the ſame Nerve, whoſe branches being ſent to the Palate and Jaws, perform the buſineſs of chewing, other ſhoots, as it were fore-runners, are carried to the Noſtrils and Eyes, to wit, that theſe Organs of the other Senſes might be furniſhed with ſome helps of probation alſo, for the better knowing or diſtinguiſhing the objects of taſte. Certainly from the nearneſs of kindred and manifold affinity of this Nerve, being alſo much diffuſed in the Head, the mutual dependencies and confederations of very many of its parts, proceed. But how this Nerve in other Provinces, to wit, in the *Thorax* and lower belly, and there about the motions and ſenſions of the *Præcordia* and *Viſcera*, doth cauſe various Sympathies of them among themſelves and with other parts, ſhall afterwards be more largely ſhewn, when we ſhall ſpeak particularly of the intercoſtal Nerve, which is rooted in this Nerve of the fifth pair; where, from the manifold communication of this Nerve, may be eaſily drawn the reaſons of ſneezing, yawning, laughing, crying, and of other actions merely natural. In the mean time, the ſuperior branching of the Nerve of the fifth pair ſhews it ſelf after this manner in the Head, and almoſt after the ſame manner is divaricated in moſt living Creatures; except however, that in ſome preſently after its riſe, it is divided into three great branches; one of which is deſtinated to the lower Jaw, the other to the Eye and Noſe, and the third to the Cheek.

The Nerve of the ſixth Conjugation follows, which ariſing out of the loweſt foot of the annular Protuberance, and being hid under the *Dura Mater*: preſently goes out of the Skull at the ſame hole with the nerves of the third and fourth pair, and is carried with a ſingle Trunk into the ball of the Eye; but ſo, that near the ſide of the Turkey Chair it is inoculated with the ſecond branch, or the greater of the fifth pair; from whence it turns back, ſometimes one little branch, ſometimes two; which being united with the branches of the fifth pair running back, conſtitute the beginning of the intercoſtal nerve. Then this nerve going forwards, is divided into two branches near the ball of the Eye; one of which is inſerted into the Muſcle drawing back the Eye planted in its outward angle; and the other being torn into various fibres, is beſtowed on the ſeventh Muſcle proper to Brutes; ſo that this nerve alſo ſeems to ſerve to thoſe motions of the Eye that are almoſt only pathetick, or excited by natural Inſtinct. For, as to the uſe of the former ſhoot, it plainly appears, that it is innate to every Animal in a ſudden fear to draw the eyes backward, and to look for what is to be feared on either ſide and behind: then as to its other ſhoot, whereby Brutes winke or twinkle the eye, it is obvious that this ſame motion is ſudden and extemporary, without any previous intention, whereby the eye endeavours to ſhun the injuries of outward things that occur.

The ſeventh Conjugation of Nerves, accounted for the fifth by the Ancients, is imployed about the ſenſe of hearing. Of this pair commonly are noted two Proceſſes, the one ſoft, the other hard; which indeed ſeem to be two diſtinct nerves, for that although they have their beginnings nigh one another, yet are ſomewhat diſtinct, and are carried to divers Organs; in the mean time either agreeing in a certain common reſpect of uſe or action. For whilſt one Nerve performs the act of hearing, the other ſupplies ſome requiſites whereby that act may be the better performed: wherefore we ſhall not much ſtrive againſt the common deſcription of this pair, by which it is taken for one. The proceſs of this pair, or the auditory Nerve properly, which is called the ſoft Branch, ſeems to ariſe in man out of the lower ſide of the ringy Protuberance, and in beaſts out of the midſt of the leſſer Ring. In ſome Diſſections I plainly found, that this ſofter Nerve, having its beginning lower, ſeemed to aſcend a little before it went out of the medullar ſtock; and the other more hard Nerve ſeeming to ariſe higher (*viz.* out of the medullar whitiſh line leading about the bottom of the fourth Ventricle) did deſcend a little, and aroſe near the meeting with the other. This ſofter Nerve is carried into the paſſage of the ſtony Bone, where entring into the den deſtinated for the receiving the ſound, which is on this ſide the Snail-like winding and the Drum, it ſo infolds it ſelf into the moſt thin Membrane wherewith that den is covered, that as often as the Air implanted in that cavern is moved by the ſtroke of the external Air made upon the Drum, this impreſſion ſtriking this Membrane, and ſtirring up as it were an undulation of the animal Spirits, is forthwith carried towards the common Senſory by the paſſage of the Nerve there implanted. There will be a more opportune place of diſcourſing, after what manner, and by what ſort of Organs Hearing is performed, when we ſhall ſpeak of the Senſes.

The other Nerve of this pair, or the more hard proceſs, which conduces rather to motion than ſenſe, paſſing through the ſtony Bone at an hole proper to it ſelf, ariſes near the auditory paſſage, where it preſently receives into its trunk a branch from the wandring pair brought thither; then immediately after that joyning together or coalition, it is divided into two branches: The firſt of theſe tending downwards, is beſtowed upon the Muſcles of the Tongue and the Bone *Hyoides*; the other going about the auditory paſſage, and bending more upwards, is divided into three ſhoots; the firſt of which, anſwering to the Nerve of the former diviſion, beſtows ſome ſhoots on the Muſcles of the Lips, Mouth, Face, and Noſtrils, and ſo actuates ſome exterior Organs for the forming the voice, as the former doth ſome interior Organs. The ſecond ſhoot of this diviſion diſtributes its ſhoots into the Muſcles of the Eyebrows

and

and Forehead; and the third into the Muſcles of the Ear it ſelf. The offices and uſes of all theſe have been already ſhewn, the ſumm of which is, that as often as the ſound is admitted in, eſpecially if it be any ways unuſual, new, or to be wondred at, preſently by a certain natural inſtinct the Ears and Eyes erect and open themſelves: to wit, for that end ſhoots from this Nerve are inſerted into the Muſcles of the Eye-lids and Ears, that by the paſſage of theſe, the Spirits inhabiting either Region, might be called out as it were to watch. For a like reaſon ſhoots from the ſame hard proceſs of this Nerve are diſtributed both into the Muſcles of the Tongue and of the Bone *Hyoides:* as alſo into thoſe of the Lips and the outward parts of the Mouth, that by their paſſage, the ſound being tranſmitted further to theſe Organs of the voice, it being equal or like the ſame, might officiouſly anſwer it as it were an *Echo.* That the deſcriptions of the aforeſaid Nerves might be better underſtood, I have thought good here to repreſent in the following Figure the branchings of the fifth and ſixth pair. The ſeventh pair is fitly delineated in the ninth Figure.

This Figure ſhews the Branchings of the fifth and ſixth pair of Nerves.

A. *The Nerve of the ſixth pair (which we place firſt, becauſe it is outmoſt in the Scheme) from whoſe trunk two ſhoots* a. a. *are carried into the two Muſcles of the Eye.*

A. *A ſhoot from the Nerve of the ſixth pair bent back for the root of the intercoſtal Nerve.*

B. *The trunk of the fifth pair being preſently divided into two great branches.*

bb. *Two ſhoots from this branch bent back for the root of the intercoſtal Nerve.*

C. *The diviſion of the upper part of the trunk into four leſſer branches, the uppermoſt of which* c. *being the Ophthalmick or belonging to the Eye, and entring the orb of the Eye, ſends forth four ſhoots.*

c. *The firſt being carried nigh to the ball of the Eye, is bent back into the Noſtrils.*

d. *The ſecond paſſing by the outward orb of the Eye, is carried into the Muſcles of the Forehead.*

ee. *The third and fourth are diſtributed into the Eye-lids and interior Glandula's of the Eye.*

D. *The ſecond branch of the ſecond diviſion is alſo Ophthalmick, which entring the ball of the Eye, and carried towards the outward corner of the Eye, is diſtributed into the Eye-lids and outward Kernels.*

E. *The third branch of the ſecond diviſion, or the maxillar, which paſſing by the orb of the Eye, enters an hole proper to the bone of the Jaw, in which paſſage it ſends forth a ſhoot* e. *through another hole into the chewing Muſcle, then ariſing up, it is carried out at the hole.*

f. *A ſhoot into the Muſcles of the Noſe.*

ggg. *It ſends forth many ſhoots into the upper Lip.*

F. *The lower branch or the fourth of the ſecond diviſion, which deſcending right towards the hollowneſs of the Mouth, is divided into two branches.*

h. *The firſt is diſtributed into the Gums.*

i. *The ſecond is beſtowed with many ſhoots upon the Palate.*

G. *The ſecond branch of the firſt diviſion of the fifth pair, which tending ſtraight downwards towards the lower Jaw, ſends forth in its paſſage many ſhoots.*

k. *A ſhoot of it into the Parotid Glandula's, or thoſe near the Jaws.*

l. *A ſhoot to the inward Mandible.*

m. *A ſhoot which compaſſing about the proceſs of the lower Jaws, is carried to the outward part of the exterior Maſticator.*

n. *Another ſhoot tending oppoſite to the former, having compaſſed the ſame proceſs, is diſtributed into the inward part of the ſame Maſticator.*

H. *The trunk of the ſame greater branch carried further, is cleft into many ſhoots, of which*

o. *Tends into the root of the Tongue.*

pp. *Is carried with many ſhoots into the ſubſtance of the whole Tongue.*

q. *Into the parts under the Tongue.*

r. *Paſſing through the bone of the Jaw, is divided into many ſhoots which are diſperſed, partly into the lower Lip* s. s. s. *and partly into the Chin* t. t. t.

The Second Figure ſhews all the Nerves, which being carried from the Nerves of the third, fourth, fifth, and ſixth Pair, are beſtowed upon the Muſcles and other parts of the Eye.

A. *The Nerve of the third pair carried to the three ſtraight Muſcles, and into the outward oblique one.*
B. *The Nerve of the fifth pair, or the pathetick Nerve, goes whole into the trochlear Muſcle.*
C. *The Nerve of the ſixth pair into the drawing back Muſcle, and the ſeventh proper to Beaſts.*
D. *The Nerve of the fifth pair whoſe Ophthalmick branch* E. *is divided into two branches,*
F. *The upper branch, being preſently torn into many ſhoots, tends directly towards the inner corner, where it is beſtowed on the Glandula's and Eye-lids.*
G. *The lower Ophthalmick branch, which being divided into ſhoots, reſpects after a like manner the Glandula's and Eye-lids towards the outward corner of the Eye,*
a. *The Nerve of the fourth pair for the trochlear Muſcle.*
b. *A branch of the Nerve of the third pair for the Muſcle lifting up the Eye-lids.*
c. *A branch of the ſame pair for the Muſcle ſhutting the Eye-lids.*
d. *A branch of the ſame Nerve for the Muſcle preſſing cloſe the Eye-lid.*
f. *A branch of the ſame for the outward oblique Muſcle.*
g. *Leſſer Nerves out of the infolding of the third pair, tending through the Sclerotick Coat into the* Uvea.
e. *The Nerve of the ſixth pair for the drawing-back Muſcle.*
*** *Fibres or leſſer branches from the fifth and ſixth pair for the ſeventh Muſcle, proper to Brutes.*
h. *A Nerve coming from the upper Ophthalmick branch into the Noſtrils.*
i. *A Nerve from the ſame branch into the Eye-brows and Fore-head.*
H. *The trunk of the fifth pair cut off, which tends to the lower Jaw.*
I. *A branch of the ſame cut off, which is carried to the Palate.*
K. *Its upper maxillar branch.*

CHAP. XXIII.

The Deſcription of the eighth Pair of Nerves.

THE Conjugation of the Nerves of the eighth pair, accounted by the Ancients for the ſixth, is called the Wandring pair; to wit, for that its Nerve, not content with one member or region of the Body, is thought to reſpect divers parts, and thoſe different, and ſituate at a great diſtance one from another, and to reach forth its branchings, not only in the neighbourhood about the Head and Neck, but through the whole cavity of the middle and loweſt Belly, and to moſt of the Bowels in either. But indeed this nerve hath a province large enough, yet not ſo diffuſe as is commonly thought: for many other nerves, inoculated into this, joyn themſelves with it, and are accounted a part of it, although they have diſtinct beginnings, and going away again from the nerve of the eighth pair, have peculiar divarications, and different from it. Wherefore, that we may give to each its own, we ſhall endeavour to proſecute this nerve of the wandring pair from the beginning to the end; and alſo ſhew the confederations and coincidences or joynings together of others with it.

The eighth Conjugation therefore of the Nerves ariſes below the auditory or hearing nerves out of the ſides of the oblong Marrow, its root conſiſting of numerous Fibres. In a man there are at leaſt twelve, ſome of which are greater, others ſmaller; to which is added a noted Fibre, or rather Nerve, much greater than the reſt, from the ſpinal Marrow, which being joyned with them, and wrapped about with the ſame Coat, taken from the *Dura Mater*, goes forth together out of the Skull, as if they all grew into one Trunk: but that acceſſory nerve, yea and many other Fibres, do ſtill remain diſtinct under that covering and afterwards departing aſunder, are carried into peculiar provinces.

Becauſe this ſpinal Nerve having paſſed the Skull, leaving its Conjugation, is carried to the muſcles of the Neck and Shoulders; beſides, the noted Fibre, out of the beginning of the wandring pair, is preſently carried into the hard proceſs of ſeventh Conjugation; and two other Fibres, having preſently left the company of the reſt, go into the muſcles of the Throat and Neck: but the reſt of the Fibres, being collected together, go forward ſtill as Companions, and inſtead of their other Companions which departed from them, they preſently get new in their places; to wit, ſometimes the whole trunk of the intercoſtal nerve it ſelf, as is ſeen in moſt four-footed Beaſts, ſometimes only a branch of it comes to them, as is obſerved in Man and ſome other living Creatures.

In this place where the trunk or branch of the intercoſtal Nerve is inoculated into the trunk of the wandring pair, a noted infolding is conſtituted, to wit, the trunk of the nerve being there made greater, ſeems to be lifted up, and to grow out into a certain Tumor like to a callous or ſinewy-ſwelled body: here, for that it is ſomewhat long, it is called by *Fallopius* the Olive body; of which ſort the ſame Author affirms, there comes to this nerve ſometimes one, ſometimes two; but in truth, one is conſtantly found in the trunk of the wandring pair, but the other in the neighbouring intercoſtal.

Of theſe ſort of infoldings in general we ſhall take notice, that they are made in the Nerves, as joynts in a Cane, or knots in the ſtem of a Tree, *viz.* as often as a branch goes out of the trunk, or ſliding into another place, is received into the ſame; and whem oftentimes ſome ſhoots go away from the place, and others come to it, the infolding there becomes greater; and ſo the more branches and ſhoots do happen to come together any where, or to go out of a nerve, the greater the bulk and magnitude of the in folding is increaſed: but if at any time a branch ſeems to proceed from any nerve without conſtituting an infolding, in truth, being included only in the ſame Coat, it is not accounted ſo much a branch as a companion which by a paſſage long before, had gone together forwards, as a ſingle nerve it ſelf, and diſtinct enough nor was it at all inoculated before its departure. But the uſe of theſe ſame infoldings ſeems to be the ſame with the knots in the ſtem of a Tree, or ſuch as the turnings aſide or by-paths that lye near croſs-ways; to wit, that when the animal Spirits, together with the nervous Juyce, inſtitute divers journies, leſt mutually, meeting, they ſhould be confounded, they may be able to turn aſide a little, and depart one from another till they may recover their orders and juſt method.

In the Deſſection of the Nerves, which are diſtributed to the *Præcordia* and *Viſcera*, the two Ganglioform infoldings, to wit, the aforeſaid in the trunk of the wandring pair, and the other near growing in the intercoſtal nerve, are as it were two bounding ſtones, which being firſt diligenly traced, the other threads of the Anatomical task, both on this and that ſide, are eaſily handled. But that theſe infoldings may be found, the trunk of the *Carotidick* Artery is laid open on both ſides between the Muſcles of the Neck; then by following its tract, the aforeſaid Olive bodies come into view about the inſertion of the lower Mandible; out of which, both the upper beginnings and the lower branchings of either nerve, may be deſigned or drawn. But becauſe about this place the nerves begin to be figured otherwiſe in a Man than in Brutes; that the reaſon of the difference may be known, we will here proſecute apart and diſtinctly the *Neurologie* or Doctrine of the Nerves of either, and firſt we ſhall deliver the *Hypotheſis* of the wandring pair, and its conſederations with the intercoſtal and other nerves, as they are found in Man.

The Ganglioform infolding therefore being conſtituted upon the Trunk of the wandring pair, receives one Nerve ſent into it elſewhere, and ſends forth another from it ſelf. To this is brought a ſhoot from the intercoſtal nerve different from moſt brute beaſts, where the whole trunk of the intercoſtal nerve comes, and ſeems to be united to the wandring pair. But from the aforeſaid infolding, a noted branch being ſent forth, is carried towards the *Larynx*, which when it is divided into three ſhoots, the firſt of them is ſtretched out into the Sphincter of the Throat; the ſecond being hid under the Scutiform or Shield-like Cartilage, diſtributes its ſhoots to the upper Muſcles of the *Larynx*, and to the Muſcles by which the chink of the *Larnyx* is ſhut up; and the third alſo entring the Shield-like Cartilage, meets the top of the returning nerve, and is united to the ſame. Such an inoculating of this nerve, with the returning nerve, is conſtantly found in man and in all other perfect Animals; the reaſon of which is delivered anon.

Below the aforeſaid infolding of the wandring pair, its ſtem, near the ſide of the aſcending Caroditick Artery, goes forward ſtraight downwards, and in its journey imparts ſome ſmall ſhoots to the ſame, which ſometimes compaſs about the trunk of its Veſſel, ſometimes are inſerted into its Coats. In the lower par of the Neck this trunk of the wandring pair admits a branch of the intercoſtal nerve from its neighbouring infolding, and in the left ſide about that place ſends forth another nerve from it ſelf into the returning nerve, which croſs branch, being ſtretched out only in the left ſide, is found in man and all brute beaſts: but from thence the trunk of the wandring pair deſcends without any noted branchings till it comes over againſt the firſt or ſecond Rib; where another infolding being made, many ſhoots and numerous fibres are ſent forth towards the Heart and its Appendix. But this divarication of the Cardiack nerves is not after the ſame manner altogether in either.

For in the left ſide one or two noted ſhoots being ſent forth, together with the other ſhoots ariſing from the intercoſtal Nerve, are inſerted into the Cardiack infolding; but many fibres going out at the ſame place, are diſtributed to the Veſſels hanging to the Heart, and to its little Ears and *Pericardium*. In the right ſide a noted ſhoot going into the greater *Cardiack* infolding, another into the leſs, and two other ſhoots from the middle infolding of the intercoſtal Trunk towards the Cardiack infolding, aſſociate themſelves and are united. Beſides, numerous Fibres in like manner deſcend into the Veſſels of the Heart and the *Pericardium*. Alſo the returning Nerve in this ſide ariſing higher, is turned back about the axillary Artery, when in the left ſide the ſame going away much lower than this infolding from the Trunk of the wandring pair, compaſſes about the deſcending Trunk of the Aorta, and from thence it is turned back upwards.

The

The returning Nerve, although it ſeems a branch ſent forth from the Trunk of the wandring pair, being indeed a diſtinct and ſingular nerve, comes even from the beginning of wandring pair; yet for better conducts ſake it is contained under the ſame Coat with the reſt of the Trunk of the wandring pair. In either ſide about the knots of reflection or turning back, it ſends forth ſhoots and fibres which are diſtributed into the Veſſels of the Heart. The reflected Nerve in its aſcent receives in the left ſide a branch from the middle infolding of the Intercoſtal, and another from the wandring pair; but either running back, diſtributes many ſhoots to the rough Artery; then its extremity meeting with the ſhoot, which is ſent out of the Ganglioform infolding of the wandring pair, is united to it.

A little below the coming away of the returning Nerve on the left ſide from the Trunk of the wandring pair, another noted branch is ſent forth on both ſides; which being carried towards the Heart, covering its Baſis in the hinder Region, meets it on both ſides, and diſperſes in all its proceſs branches through the whole Superficies of the Heart. As ſhoots go from theſe branches into the hinder part of the Heart, ſo many branches and ſhoots go from the Cardiack infoldings which are divaricated into its fore-part.

But there are two infoldings from which the Nerves are diſtributed into the Heart, The upper and greater is between the *Aorta* and the Pneumonick Artery. The nerves conſtituting this are one or two noted branches that deſcend hither from either ſide the Trunk of the wandring pair; but chiefly many nerves form either intercoſtal nerve, to wit, from the midſt of its infolding. From this infolding two or three noted nerves are carried under the Aorta into the left ſide of the Heart. But from this infolding a ſhoot being ſent forth, making as it were an handle, compaſſes about the pneumonick Artery; and a branch deſcending from the right Trunk of the wandring pair to the exterior part of this handle, and another, which being carried from the nerve which is deſtinated to the hinder region of the Heart, meet together and make the leſſer infolding; from which nerves are ſent into the right ſide of the fore-part of the Heart.

We are to take notice, That in brute Animals many more and far greater Nerves are carried from the Trunk of the wandring pair into the Heart and its Appendix than in Man, to wit, in whom the chief Cardiack nerves or belonging to the Heart proceed from the intercoſtal pair, as is ſhewed below; wherefore in Brutes, for that reaſon, the wandring pair affords greater ſupplies or ſubſidies to the Heart, becauſe the intercoſtal nerve ſcarcely contributes any to it. Further, through the whole tract of the wandring pair, from whence the Cardiack nerves proceed, very many ſmall ſhoots, being ſent forth on both ſides, are inſerted into the *Oeſophagus* and the Glandula's implanted without the *Pericardium*.

From the Region of the Heart, the Trunk of the wandring pair ſends forth many noted ſhoots on both ſides, which being carried into the Lungs, are diſtributed, together with the blood-carrying Veſſes, through their whole ſubſtance, and in their paſſage ſtep by ſtep they follow the Pipes of the *Bronchia*, both the Arteries and the Veins, and many ſhoots being ſent forth on every ſide, they climb upon and compaſs about theſe Veſſels; then the Trunk of the ſame wandring pair, deſcending on both ſides, nigh the ſides of the *Trachea*, diſtributes many ſhoots alſo into the Coats of the *Oeſophagus*.

Below the Pneumonick branches, either Trunk of the wandring pair going forwards downwards nigh the ſides of the *Oeſophagus*, is divided into two branches, *viz.* into the exterior or more outward, and the interior or more inward. Both the inward branches inclining towards one another mutually, do again grow into the ſame Nerve, which being ſent ſtraight down towards the *Oeſophagus*, and being carried nigh the inward part of its Orifice, is bent back from thence, and creeps through its upper part. From both branchs, being carried nigh the oppoſite parts of the ſuperior Orifice, many ſhoots are produced, which being mutually inoculated, do conſtitute the nerves infolding like a little net. The Stomachical lower branch ſends forth very many fibres and ſhoots nigh the left part of the bottom of the Ventricle, which are united with others, ſent forth from the Meſenterick and Splenetick infolding. Further, in the right part of the ſame bottom of the Ventricle, ſhoots being ſent forth from either Stomachical branch, are united with other ſhoots ſent upwards from the Hepatick infolding; and about this place either Trunk of the Nerves of the eighth pair ſeems to be terminated, for that the laſt that may be perceived of it are ſome ſhoots ſent forth from the Stomachical branches, which are inoculated or ingraffed with the little branches or fibres ſent upwards from the Meſenterick infoldings.

CHAP. XXIV.

The Actions and Uſes of the Nerves of the eighth Pair, deſcribed in the foregoing Chapter, are unfolded.

AFter this manner the beginning and branchings out of the Nerves of the eighth pair are diſpoſed in Man: and they are almoſt after the ſame manner in Brutes, unleſs the Cardiack branches be more, becauſe in theſe they go out only from this one Conjugation. The Figure or Type of all theſe is well deſigned or drawn in the ninth Table or Figure. It now remains, recollecting the Tracts of this Deſcription, or at leaſt the things chiefly to be noted, that we inquire into the Reaſons of their *Phænomena* or Appearances.

This Nerve, preſently after its riſe, appears with numerous Fibres, as may be diſcerned in the ninth Figure *E*: the reaſon of which is, becauſe many nerves here ariſing together, and deriving plenty of animal Spirits from the ſame ſtock or proviſion, ought to carry the ſame to divers parts, and remote one from another; and therefore they aſſume their *Latex* or Juyce, not at one Trunk, as the blood carrying Veſſels, and afterwards diſtribute it equally by branches and ſhoots here and there ſtretched out; becauſe the Spirits, derived from the ſame Fountain, have need to flow into theſe parts ſeparate from them, and variouſly to tranſpoſe and change their influence: wherefore for this buſineſs it is required (that we may not ſuppoſe little doors in the middle of the branchings out of the nerves, as are in the Pipes of a muſical Organ) that the nerves, which are deſtinated for the performing of divers offices reſpectively in diſtinct parts, ſhould be ſingle in their whole paſſage, and of themſelves diſtinct chanels of Spirits; for the ſake of a better conduct many of them are collected together, and ſeem to grow together into one Trunk, but they are parted both in their beginning, and alſo in their whole journey, and diſtinguiſhed, though involved in the ſame Coat, and ſo are carried to the reſpective parts. Otherwiſe how ſhould it come to paſs, that the Spirits to be carried for the performing the inſtinct of motion towards the Stomach, do not enter at the ſame time the Lungs or *Præcordia*, and actuate them with an inordinate influence? For indeed the ſhoots of the nerves of the wandring pair may be followed by the eyes and hand backwards towards the beginning, from the parts into which they are inſerted, and where they ſeem to be united into the ſame Trunks ſo ſeparated with the finger, that it may appear they are ſingle. After the ſame manner we have plainly ſeparated one from another the returning nerve alſo, and others, their common Coat being diſſected. Yet in the mean time we deny not, that in their progreſs they do communicate one with another by Fibres meeting mutually, if it be granted, that the ſame, although they ariſe together, in their very riſe it ſelf are in a manner diſtinct. For by reaſon of the nearneſs of the beginning and progreſs, though all the nerves of the wandring pair have a certain Sympathy and conſent in their actions; yet for that they conſiſt of parted ſtrings, they perform their actions ſucceſſively, and convey the influences of the Spirits to theſe parts ſeparate from theſe.

We have already ſhewn, that the Nerve of the wandring pair, and others belonging to its family, do ſerve almoſt only to the involuntary Function. Wherefore it may be thought, that as there are many ſhoots and fibres, which going out diſtinctly from the ſame origine, are carried to divers parts, that indeed thoſe Bowels and Members, into which theſe nerves are inſerted, do perform their particular actions, ſtirred up either by the inſtinct of Nature, or by the force of the Paſſions, the Animal in the mean time ſcarce knowing it: yea alſo, that when certain other nerves, ariſing afar off, are joyned to this Trunk of the wandring pair, and communicate with it near the very origine of it; this ſeems to be therefore done, that thoſe nerves, an affinity with the wandring pair being begun, may be drawn into Sympathy with it, and into an unity of action of the involuntary Function. This appears clearly by the acceſſory nerve from the Back-bone, and ſome others, as ſhall be manifeſted anon.

In the mean time, we ſhall obſerve concerning the Fibres of the wandring pair, firſt that a noted ſhoot, inclining towards the vocal proceſs of the ſeventh pair, is united with the ſame, as in the ninth Figure *e*. Hence a reaſon may be taken, wherefore in every violent Paſſion, as of Anger, Fear, Joy, and the like, without the will or intention of the Animal, the Tongue ſends forth a voice, as an index of the excited affection; ſo that not only men, but ſome brute beaſts, in their fleeing or rejoycing, wail, cry out, and make a noiſe.

Secondly, from the beginning of the wandring pair very many Fibres are diſtributed into the Muſcles of the Neck, Figure the ninth *FFF*. in which there ſeems little need of the ſtirring up of ſpontaneous motions in that part; for to this task the Vertebral nerves ſerve ſufficiently. Notwithſtanding the aforeſaid Fibres of the wandring pair are the cauſe why the Neck is moved about in fear, or at any noiſe or ſuſpicion of danger; and alſo, why in ſome Animals, from indignation or pride, the Muſcles into which theſe nerves are inſerted, being inflated very much, their necks ſwell up, and the Creſts of many are erected. Of how great uſe the acceſſory nerve, coming from the Spine to the wandring pair, is for the pathetick motions of the Arms, ſhall be ſhewed preſently.

Thirdly,

Thirdly, The other Fibres of the wandring pair, being gathered together, ſeem to grow together into the ſame Trunk, which preſently conſtitutes the Ganglio form infolding from a ſhoot coming from the intercoſtal nerve, as in Figure the ninth *G. H.* And indeed it is very likely, that of theſe Fibres, which are complicated together in the Trunk of the wandring pair, one is deſtinated to the returning nerve, another to the *Præcordia*, a third to the Lungs, and laſtly, another to the Ventricle; all which, although they have communication among themſelves, and for the ſake of a better conduct are gathered together in one, yet they are ſtill diſtinct from their very original, and conſtitute divers paſſages of the animal Spirits.

But that a ſhoot is carried from the intercoſtal Nerve into the upper infolding of the wandring pair, as in the ninth Figure *b*; the reaſon is, that between theſe nerves a certain ſtrict affinity and kindred might be, and that either of them might be affected with the others offices. For as the nerve of the wandring pair diſtributes ſhoots chiefly to the *Præcordia*, and the Stomach, and the intercoſtal Nerve to the reſt of the *Viſcera* of the lower Belly; we may obſerve, that between all theſe there are not only ſome commerces, but Sympathies, and a conſent of Actions and Paſſions; wherefore there is a neceſſity, that the nerves deſigned to either parts, ſhould communicate among themſelves. Further, in Man the intercoſtal nerve imparts to the Heart and its Appendix more ſhoots and fibres than the nerve of the wandring pair: wherefore theſe nerves, do not only communicate by theſe ſuperiour infoldings, but alſo again a little lower by a ſhoot ſent out from the cervical infolding, or that of the Neck.

From the aforeſaid infolding a noted branch of the wandring pair is ſent forth into the Muſcles of the *Larynx*, a certain branch of which, entring the Shield-like Cartilage, meets with the returning nerve, and is united to it *Fig. 9. b.* It will not be difficult to collect what the uſe of this nerve may be; for ſeeing the *Larynx* or the rough Artery ſerves both for the drawing in and putting out of the breath, and alſo for the modulating the voice; for either office that its Trunk, like the folds in a pair of Bellows, may become ſometimes more ſhort, ſometimes more at length, theſe ſame ringy Cartilages ought to be pulled together, or contracted ſometimes upward, and ſometimes downward. That a flat voice or ſound might be formed, they ought to be preſt down as much as may be to the bottom; but if you would form a more ſhrill or ſharp ſound or voice, the ſuperiour Rings are lifted up; to wit, that the ſound might be broken but only in the very paſſage of the Jaws. For the performing of this double motion of the *Larynx* two nerves are conſtituted like the hands of a Piper, one of which ſtops the lower holes, the other the upper of the Pipe: to wit, the ſhoots and branches of the returning nerve being lifted up from below, move the ringy Cartilages downwards; and the nerve ſent out from above from this infolding, preſently draws the more ſuperior upwards. Further, becauſe a certain conſent and joynt action is required in both nerves, therefore they are mutually inoculated or ingraffed: yea, whenas either of them returning, diſtributes frequent ſhoots into either ſide of the *Trachea*; it ſeems that thoſe that are ſent out into the right part, move its Rings downwards for Inſpiration and a ſtrong Voice; and the others, going out on both ſides into the left part, carry the Rings upward for Expiration and for an acute or ſharp Voice. Moreover, as the inſtinct for the motion of depreſſion or preſſing down is delivered from the knots of the recourſe or reflections; ſo the impreſſion, for the elation or lifting up of thoſe parts, is received from this nerve of the *Ganglioform* infolding.

A noted branch from the middle infolding of the intercoſtal Nerve is carried into the Trunk of the wandring pair, *Fig. 9. i.* For what end that is ſo, we have ſhewn already; to wit, that the commerces of the Spirits dwelling in both nerves, might be ſtrengthened: but it ſhould be noted, that it is only ſo in the left ſide where the Trunk of the wandring pair ſhews it ſelf ſingle for a long ſpace; but in the right ſide, where the returning nerve goes from it much higher, here the other nerve from the intercoſtal infolding is plainly wanting.

About the Region of the firſt or ſecond Rib, another noted infolding appears in the Trunk of the wandring pair, from which many ſhoots and fibres are ſent towards the Heart and its Appendix, *Fig. 9. k.* Further, in brute Animals, about this place, the intercoſtal nerve leaves the Trunk of the wandring pair. Without doubt, ſome animal Spirits go apart in this infolding, which are deſtinated to the anterior region of the Heart, alſo to the *Pericardium* and ſome of its Veſſels, whilſt other Spirits paſs through, which a little lower are derived into the hinder region of the Heart; and which being yet carried further, go to the Lungs, and laſtly to the Ventricle.

We may obſerve, that from the aforeſaid infolding of the wandring pair numerous ſhoots and fibres are ſent forth, which are diſtributed into the little ears of the Heart and all the ſanguiferous Veſſels belonging to the Heart, *Fig. 9. l. m.* which fibres and nervous ſhoots creeping along like Ivy, thickly cover over the Coats of the Veſſels, and enter them in very many places, and variouſly bind them about. Truly this copious diſtribution of the nerves doth effect the pulſifick force in the little ears of the Heart and in the Arteries, or at leaſt ſeems to excite it; and ſo to erect and ſtrengthen thoſe parts by a continual influx of the animal Spirits through theſe nerves, that they may be able to ſuſtain an undiſcontinued reciprocation of *Syſtole* and *Diaſtole*. Moreover, that the thick fibres and ſhoots of the nerves are inſerted both into the Veins and Arteries, and bind both thoſe kind of Veſſels, and variouſly compaſs them about, we may lawfully ſuppoſe, that theſe nerves, as it were Reins put upon theſe blood-carrying Veſſels, do ſometimes dilate, and ſometimes bind them hard together for the determining the motion of the Blood according

according to the various force of the Paſſions, or to deduce it here and there after a manifold manner; for by this means it comes to paſs, that in fear the excurſion of the blood is hindred, and in other Affections its motion is reſpectively altered.

But that many ſhoots and branches are inſerted into the *Pericardium*, it ſeems to be for this uſe; to wit, that that little Cheſt which is made like a Fort for the defending the Heart from injuries, as often as any troubleſom matter aſſaults or beſieges it, might be able to draw it ſelf together, and to ſhake off the enemy. For it ſeems, that the inordinate tremblings and ſhakings of the Heart, which are manifeſtly different from its natural Pulſe, proceed from the violent ſhaking of this Membrane.

As to the Cardiack branches ſent from this infolding, we obſerve, that they, becauſe deſtinated to a publick office, do therefore communicate and enter into the pairs of either ſide before they are inſerted into the Heart; for which end the infolding is made before the Baſis of the Heart, where the aforeſaid ſhoots from the wandring pair and many others, going out from either intercoſtal nerve, meet together. From that infolding, placed betweem the *Aorta* and the pneumonick Artery, very many branches being ſent forth above, cover over the Hemiſphere of the Heart: but yet from theſe certain branches, carried under the *Aorta*, are brought into the left ſide of the ſaid Hemiſphere; and as other pairs tend towards the right ſide, one of the firſt of them, making a little handle, binds about the pneumonick Artery; then meeting with other Cardiack ſhoots, makes the leſſer infolding, out of which branches are ſent forth into the right and anterior ſide of the Heart. That from the greater Cardiack infolding, nerves departing one from another, do inſtitute contrary journies towards the Heart, it is indeed, that they might come to divers regions of the Heart without meeting one another, and might affect its Veſſels reſpectively in their paſſage; to wit, the branches carried this way, inſert their ſhoots into the *Aorta*, and from the others going that way, one compaſſes about the pneumonick Artery. The reaſon of both ſeems to be, that the blood might be either ſooner or ſlower drawn from the boſoms of the Heart for its various need or neceſſity. For whilſt the aforeſaid nerves do both ſuſtain its motion by their influx, and alſo moderate and temper it by their inſtinct, it ſo comes to paſs from thence, that thoſe Veſſels alſo, being affected by the ſame nerves, do further compoſe themſelves to the requiſite Analogies and proportions of the Pulſes.

Indeed there are many Nerves, and thoſe conſpicuous enough, which are inſerted into the Heart, and cover its outward ſubſtance with ſhoots ſent forth from all ſides; yet it is not to be thought, that theſe nerves alone perform and ſuſtain the undiſcontinued motion of the Heart: becauſe ſo ſmall little ropes ſeem too unequal for the perpetual agitation of ſuch a Machine. Yea it may be obſerved, that more ſhoots and fibres of nerves are diſtributed into the little ears of the Heart and the depending Veſſels, than into its frame or ſubſtance. Further, it is obvious to any that will behold it, that there is a greater plenty of nerves deſtinated to the Lungs, Liver, Spleen, Ventricle, or Reins, than to the Heart it ſelf; ſo that ſome Anatomiſts (a *Fallopius* ſays) were doubtful, whether there were any nerves that belonged to the Heart or not. But this being clear enough, that we may deſcribe the motive power of this Clock or Machine ſtirred up by the help of ſome ſmall nerves, as it were an exploſive motion, we ſay that the ſubſtance of the Heart it ſelf conſiſts of a very fibrous fleſh, and may rather be called a Muſcle than *Parenchyma* or congealed ſubſtance: wherefore in this, as in other Muſcles, the implanted and proper fibres cauſe the local motion and conſtant ſhaking; but by the inſerted nerves is only conveyed the inſtinct of the motion or action; for the performing of which office, both fewer Nerves and fewer animal Spirits flowing in through their paſſages, do ſuffice. But indeed we ſuppoſe, that the animal Spirits implanted in the Heart, and abiding within its Fibres, did at firſt flow thither through the nerves, and that by this way their expences or loſs are made up or ſupplied; yet that the animal Spirits, which ſeem to be diſpenſed to the Heart by ſo ſparing an hand, may ſuffice for the actuating this perpetual motion, they receive continually ſubſidiary Forces from the arterious blood. For elſewhere we have ſhewed, that in the Heart, as in the whole muſculous ſtock beſides, a ſulphureous Copula, from the ſuggeſted blood, is joyned to the ſpirituous ſaline Particles of the implanted Spirits; which matter, whilſt the Spirits are agitated, being at length ſtruck off, and as it were exploded (juſt like the rarified and in kindled Particles of Gun-powder) for the effecting the motive endeavour, do blow up or intumifie the Muſcle or the Heart it ſelf; and ſo from the indiſcontinued action of the Heart much of this ſulphureous Copula, which is eaſily ſupplied from the blood, and leſs of the Spirits, which are brought by the paſſage of the nerves, is beſtowed.

And here it may be rightly inquired into, whether the Pulſe of the Heart ſo neceſſarily depends on the influenc of the animal Spirits through the Nerves, that it being hindred, the action of the Heart ſhould wholly ceaſe? For the deciſion of this, we once made a tryal of the following Experiment upon a living Dog. The skin about the Throat being cut long-ways, and the Trunk of both the wandring pair being ſeparated apart, we made a very ſtrict Ligature; which being done, the Dog was preſently ſilent, and ſeemed ſtunned, and ſuffered about the Hypochondria convulſive motions, with a great trembling of the Heart. But this affection quickly ceaſing, afterwards he lay without any ſtrength or lively aſpect, as if dying, ſlow and impotent to any motion, and vomiting up any food that was given him: nevertheleſs his life as yet continued, neither was it preſently extinguiſhed after thoſe nerves were wholly cut aſcunder; but this Animal lived for many days, and ſo long, till through long faſting, his ſtrength and ſpirits being worn out, he died. The carcaſs being opened, the blood within the Ventricles of the Heart, and the Veſſels on every ſide reaching from thence, to wit, both the Veins and Arteries,

teries, being greatly coagulated, was gathered into clotters; to wit, for this cauſe, becauſe the blood, though for the ſuſtaining of life, it was in ſome meaſure circulated, yet for the moſt part it ſtagnated both in the Heart, and in the Veſſels. The cauſe of which ſtagnation I can aſſign to no other thing, than that the *Præcordia*, the influence of the animal Spirits being hindred, wanted its uſual motions.

If it ſhould be further demanded, from whence the animal Spirits (the paſſage of both the wandring pair being ſhut up) ſhould be ſupplied to the Heart continuing ſtill its motion; I ſay, that this may be done by the returning Nerves, as from the knots of which many Cardiack ſhoots and fibres proceed; and beſides, the end of either nerve meeting with the nerve ſent from the upper infolding, is united. But we ſhewed already, that the animal Spirits may be carried either this way or that way within the paſſages of the nerves; wherefore when the neceſſity of life urges, the proviſion of the Spirits, though leſſer, being ſent from the aforeſaid infolding, is received by the tail of the returning nerve, and from thence by a retrograde paſſage it was derived into the Cardiack branches, and at length into the Heart it ſelf. Further, there lyes open alſo another paſſage, and that perhaps more obvious, through the paſſage of the intercoſtal nerve: by this way in a man, as well as by the paſſage of the wandring pair, the Spirits are conveyed from the Brain to the *Præcordia*; yea alſo in Brutes a branch is carried into the Trunk of the wandring pair from the intercoſtal infolding; ſo that by this by-path ſome little rills of the animal Spirits (if by chance their influence ſhould be hindred through their wonted chanels) might be carried to the Heart. However that Experiment ſeems to conclude, that the motion of the Heart depends no leſs upon the inflowing of the blood, than upon that of the animal Spirit: the total privation of either takes away life; and Eclipſe of the Spirits wholly takes away from the Heart its motive power; and by the defect of the blood (foraſmuch as the ſulphureous Copula is denied to the Spirit implanted in the Heart) the vigour and elaſtick force of the Heart is ſuppreſt, ſo that the Pulſe being by degrees weakened, life is by little and little extinguiſhed. Without doubt, in the finding out the tenour of the Pulſe, we ought always to mind what the alteration of the animal Spirits, and what the fault of the blood may bring to it.

There is yet another conſideration concerning the Nerves reaching from the Trunk of the wandring pair to the Heart, to wit, that by their paſſage, not only the ſolemn influence and ſtate of the Spirits, for the equally performing of the vital Function, is conveyed; but alſo the inſtinct of every irregular motion, ſtirred up in the *Præcordia* by the force of the Paſſions, is in ſome meaſure transferred this way. I ſay, as to theſe, we ought to diſcourſe and to ſhew by what means, as often as the impreſſion of any Affection exerciſes the Imagination, or rather the Appetite, preſently the *Præcordia* are diſturbed by the paſſage of the Nerves, and by reaſon of their various Affections the motion of the blood is diverſly altered. But becauſe in a man the irregular and extraordinary motions of the *Præcordia* depend on the intercoſtal Nerve as much as and perhaps more than on the wandring pair; therefore we think good to defer this Speculation till the Theory of that Nerve is propoſed. In the mean time, we will proceed to the other branches of the wandring pair; and what next follows, we will inquire into the offices and uſes of the returning Nerves.

The returning Nerve in the left ſide, going away from the wandring pair below the aforeſaid infolding, and ſent towards the *Aorta*, is reflected or turned back about its deſcending Trunk, from whence being carried upwards, it imparts ſhoots to the Muſcles of the *Trachea* and the *Larynx* ſent forth by a long tract from either ſide of the Nerve; then its top or height is united with a ſhoot meeting it out of the Ganglioform infolding, *Fig. 9. n.* **** *b* But the returning Nerve on the right ſide is reflected much higher about the axillary Artery, to wit, proceeding from the lower infolding of the wandring pair, and after the ſame manner is beſtowed on the other ſide of the *Trachea*, *Fig. 9. L.* But either returning back about the knots of reflection, ſends forth towards the Heart very many ſhoots and fibres, which are inſerted into its little ears, the appending Veſſels or its Infoldings.

What the chief uſe of this Nerve is, we have already ſhewn; to wit, being rolled about on both ſides the Artery, as it were a Windlace, it cauſes the little rings of the *Trachea* or Weaſand to be drawn hither and thither, like the folds of a pair of Bellows, both for breathing and making a ſound. But indeed either Nerve, foraſmuch as it being reflected about the Artery, is carried upward into the part to be moved, doth move downwards the little rings of the *Trachea* or Wind-pipe by certain ſhoots of it; alſo foraſmuch as either is terminated in the Nerve, ſent from the Ganglioform infolding, it carries upwards the folds of the *Trachea* by other ſhoots of it. Hence a reaſon may be given, why the returning Nerves being cut off, every Animal is preſently dumb; to wit, becauſe, unleſs the *Trachea* be moved, the breath being blown out, paſſing without any refraction through its cavity, as it were through a Pipe alike hollow in its whole paſſage, gives no ſound.

Concerning theſe Nerves we ought to inquire, what is the reaſon of the difference, that the knots of reflection are not alike on both ſides; alſo for what end the Cardiack branches proceed from both knots. As to the firſt, that the left returning Nerve, not as its pair, binds about the axillary Artery, ſome reaſon ſeems to be, becauſe the left axillary Artery, ariſing below, is carried as the right, by a bending, and not a ſtraight paſſage, into the Arm; wherefore the little cord of the Nerve, compaſſing about its Trunk, hath no fixed, but a very moveable knot of reflection, for that it might eaſily ſlide from its place. But it may rather be ſaid, that it is for other uſes, and thoſe more neceſſary, that theſe Nerves com-

paſs

paſs about thoſe Veſſels after that manner. For when they, as it were Reins or Bridles caſt on the blood-carrying Veſſels, by pulling them hither and thither, variouſly determine the courſe of the blood, it ſeems to be required, that one returning Nerve ſhould bind together or conſtringe the axillary Artery, and the other the deſcending Trunk of the *Aorta*: for as often as there is need for the blood to flow forwards towards the Head more plentifully, the returning Nerves perform it eaſily, by pulling upwards the aforeſaid Arteries: but the blood, after a ſort, ought to be continually urged into the higher parts, leſt otherwiſe by its weight it ſhould turn too much downwards; wherefore in all Expiration or breathing forth, when the *Trachea* drawing nearer together its folds, is contracted upwards, the blood about to deſcend the *Aorta*, is ſnatched upwards by one tract of the nervous little cord, and in like manner, the axillary Artery in the right ſide being ſhaken with it, the blood flowing in the whole aſcending Trunk of the *Aorta*, is driven upwards a little ſwifter.

But beſides this continual and equal ſnatching up of the blood towards the upper parts, it is ſometimes occaſionally urged towards the Head by a more intenſe and quick motion of the *Trachea*, and alſo by a more full and ſwift courſe. For as often as any Animal grows angry, the voice preſently ſhews ſigns of ſuch an Affection, and oftentimes by chiding, they make it ſharp; as men, when they are angry, chide or brawl, and Dogs bark: Now from ſuch an intenſion of the voice and chiding, as the upper rings of the *Trachea*, a reciprocation being there made, are often ſtruck together; ſo the blood alſo (the *Aorta* being ſtrongly drawn) is urged upwards by a copious afflux, ſo that it preſently dyes the countenance and eyes of angry people with a redneſs, and induces to the Brain it ſelf a greater heat and provocatives to anger, and a greater glowing or inflaming to the Spirits by ſtirring them up. For the ſame reaſon, in Joy and Gladneſs, foraſmuch as the *Trachea* is exerciſed by ſinging or laughing, the blood alſo is poured out more plentifully towards the exterior, and eſpecially the upper parts.

And from hence the cauſe is plain, wherefore either returning Nerve ſends forth Cardiack branches from the knot of reflection or turning back; to wit, that in thoſe kind of affections, the notice of which the *Trachea* in ſounds or voices gives by the help of the Nerves, the Heart it ſelf by its means alſo might be affected, For ſo, as often as we wrangle or brawl, the Heart being irritated, preſently inkindles the blood more, and drives it forward more plentifully, as food for thoſe Affections, towards the Brain. Alſo in laughter, great rejoycing, or ſinging, by the paſſage of thoſe Nerves, the Heart being brought into a conſent or Sympathy, or joynt action, preſently explodes or drives out the blood by a ſwifter pulſe, and caſts it haſtily out, which otherwiſe would be heavy and troubleſom by a ſlower motion or ſtagnation; wherefore thoſe ſorts of actions, to wit, laughing and ſinging, are ſaid to alleviate the Heart, becauſe they make the blood more freely and readily to be poured out of the boſoms of the Heart, and alſo by the ſupplying help of the Lungs, to be emptied into the ſame.

Below the production of the left returning Nerve another noted Nerve is carried towards the hindermoſt region of the Heart, which being carried with a certain compaſs about its Baſis, ſends forth frequent ſhoots, which cover the left ſide of the hinder Hemiſphere, *Fig. 9. o.* Then this branch meeting with another pair ſent from the oppoſite ſide towards the Heart, and diſtributing ſhoots into the right ſide of the hinder Hemiſphere, is united with it, *Fig. 9. q.*

This Cardiack branch, deſtinated to the hinder region of the Heart, is produced apart below the reſt, that it might be carried by it ſelf to its Providence without the meeting with or implication of others; the pairs are ingraffed on either ſide, that they might accompany one another, and be together drawn in the ſame action of the Heart. It appears not plain, whether theſe nerves conſpire with the other Cardiack nerves, ariſing above, reaching forth to the anterior Hemiſphere of the Heart; or whether this pair effect not the *Syſtole* of the Heart, and the upper its *Diaſtole*. However it is, certain ſhoots of the kindred or ſtock of either, being ingraffed with others of another ſtock, communicate one with the other.

The Trunk of the wandring pair ſends forth on both ſides very many noted branches from the region of the Heart, which are ſpread on either ſide into all the Lobes of the Lungs, the *Bronchia* of the *Trachia*, and the Coat of the *Oeſophagus* hard by deſcending, *Fig. 9. s.s.s.* Thoſe which go into the Lungs paſs every where through their whole ſubſtance, following the ramifications of the Veins and Arteries, and the Pipes of the *Bronchia*, which chanels of blood and air they variouſly climb over, and bind about through their whole tract.

When that ſo many noted branchings of the Nerves are beſtoweed on the Lungs, it is a wonder, that by ſome they ſhould be thought to be inſenſible and immoveable of themſelves. Yea it is doubted by many, whether theſe Bowels do cauſe the motions of the *Syſtole* and *Diaſtole* of themſelves by their own endeavour. For that it is a received Opinion, That this reciprocation of the Lungs doth proceed wholly from the motion of the *Thorax*, and doth obey or obſerve its dilatation or conſtriction with a certain neceſſary dependency; *viz.* that the Breaſt being dilated or ſpread open after the manner of a pair of Bellows doth compel the ambient Air into the *Trachea*, which ruſhing into the Lungs, blows up and diſtends them; then the ſame Breaſt ſubſiding or ſinking of it ſelf, that the Lungs being preſſed together with the weight of it, do breath forth the Air before intruded. In truth, however that I might judge, that the *Diaphragma* and the Muſcles of the Breaſt do conduce much to Reſpiration; yet that theſe parts ſhould perform this office alone, and that the Lungs are merely paſſive, I cannot grant. For Reſpiration is chiefly inſtituted for the ſake of the blood and the Heart, and its act is wont to be determined according to the various diſpoſition of theſe, and to be altered every

every minute of an hour almoſt according to the manifold neceſſity of the Pulſe. But indeed the Lungs themſelves are they (and not the *Diaphragma* or the Muſcles of the *Thorax*) which the blood, boiling out of the Heart, paſſes through, and continually affects according to its temper, and the tenour of the Pulſe: wherefore from hence it may be concluded, That the Lungs themſelves do conceive the firſt inſtincts of their motions, and by the help of the aforeſaid Nerves, do in ſome meaſure exerciſe themſelves, and endeavour the *Syſtole* and *Diaſtole*, and deſign them according to the ſenſe of its proper neceſſity; but when in theſe, Fibres requiſite for local motion are wanting, therefore the *Diaphragma* and the Muſcles of the *Thorax* help continually the endeavours of the Lungs, and by the cooperation of theſe, compleat breathing is effected. And ſo when Nerves of a twofold kind, to wit, ſome from the Spine being inſerted into the Muſcles of the *Diaphragma* and the *Thorax*, and others from the wandring pair diſtributed into the Lungs, actuate the Organs of Reſpiration; for that reaſon it comes to paſs, that the act it ſelf of Reſpiration, of it ſelf unforced and involuntary, may be at our pleaſure ſomewhat reſtrained, interrupted, and diverſly altered. The *Sympraxis* or joynt action of the Nerves of either kind, in the work of Reſpiration ſhall be ſhewed hereafter, when we ſhall ſpeak particularly of the Nerve of the *Diaphragma*.

It yet appears more plain, that the Lungs are oftentimes the chief in the act of Reſpiration, becauſe they being irritated from ſtrange and improportionate objects, preſently conceive irregular and violent motions; as when a vehement Cough is ſtirred up for the exclution of any troubleſom thing; to which motion the *Diaphragma* and the Muſcles of the *Thorax* preſently obey. In like manner, in difficult and ſighing breathing, or any other ways unequal, its firſt inſtinct for the moſt part is begun by the Lungs; yet ſometimes when the exterior Organs of Reſpiration are excited into irregular motions, the Lungs alſo are compelled to follow their irregularities; ſo when the *Diaphragma* after a manner begins laughter, the Lungs perform the ſame with a following cackling ſound: ſo all the Organs of Reſpiration intimately conſpire and agree among themſelves, that although one of them do a thing inordinately, rather than there ſhall be a Schiſm, the reſt do imitate or follow its irregularity.

But that the Nerves, following the Arteries and Veins through the whole frame of the Lungs, do variouſly bind about and cloath their Trunks with a thick ſeries of ſhoots, the reaſon ſeems to be, both that the Coats of the Veſſels being gifted with a conſtant influx of animal Spirits, might inmitate the motion of the Heart; and by that means, by a continual pulſation of the Arteries and the conſtriction of the Veins, they might eaſily carry the blood in this its more ſhort luſtration through the Lungs; and the rather, that the pneumonick Veſſels, being bound about with ſuch Reins of Nerves, might moderate the courſe of the blood according to the forces and inſtincts of the Paſſions. For whenas the exterior circulation of the blood depends upon this interior; as the blood is commanded to paſs ſooner or ſlower through the Lungs, or to ſtay there and be hindred, the excurſion and return of it alſo from or towards the Heart is wholly performed. In Joy or Anger, becauſe the Lungs rapidly tranſfer the blood out of one boſom of the Heart to the other; therefore its ſwifter and more plentiful flowing out into the outward parts, follows. In like manner, in Fear and Sadneſs, for that the Lungs (its Veſſels being ſtrained together) deliver the blood to the Heart by the Veins, and do not then preſently carry it back by the Arteries, the outmoſt region of the Body is deſtitute of its due influx. Notwithſtanding theſe kind of pathetick ſnatches of the blood are in ſome meaſure performed, becauſe its Veſſels are bound about in other places in like manner with the Nerves. If at any time Spaſmodick Affections ſhonld afflict the pneumonick Nerves from a morbific cauſe, ſo that being twitcht with inordinate motions, they ſhould pull or draw together here and there the Arteries and Veins which they embrace; for that cauſe, the blood either too much flowing out of the Lungs, makes them to flag, and to fall together into themſelves, ſo that drawing to them copiouſly the Air, they do not eaſily render it back again; or, which frequently happens, the blood being detained within the Lungs, and there ſtagnating, ſtuffs them up, and holds them a long while ſtiff, that they cannot inſpire or draw in the Air. The Symptoms of either kind ordinarily happen in the Hyſterick diſtempers, and in ſome Hypochondriacal. Yea ſometimes the *Bronchia* themſelves are pulled together by the like Convulſion of the Nerves, and are hindred in their motion, ſo that they cannot take in and ſend forth the Air after its due manner, as may be ſeen in Aſthmatical Fits. The diſtempers of which ſort are oftentimes produced by the fault of the Nerves, without any implanted Dyſcraſie or evil diſpoſition of the Lungs. I have ſometimes obſerved ſome Cales of ſick people, in which, when at one time the morbifick matter beſieging the Brain, had induced Lethargick or Vertiginous Symptoms, a little after the ſame matter occupying or poſſeſſing the origines or middle proceſſes of the nerves belonging to the Lungs, has ſuddenly excited a moſt horrid Aſthma without any previous Cough or Catarh.

But that out of the ſame tract of the wandring pair many ſhoots are diſtributed into the Lungs and alſo many others into the Coats of the *Oeſophagus*; from hence a reaſon may be given, why a troubleſom Cough oftentimes cauſes Vomiting and a ſubverſion of the Ventricle; why alſo on the other ſide a pertubation of the Ventricle ſo frequently induces a troubleſom endeavour of Coughing. I have known in Hypochondriacks, that aliments of ill digeſtion, taken into the Stomach, have preſently excited a vain and very pertinacious Cough; in the mean time, that the Lungs were free from any conſumptive diſpoſition. The cauſe of either diſtemper ſeems to be, that when the nerves, diſſeminated in either part, are taken with a Convulſion, oftentimes thoſe which are of the other part, are drawn into a conſent of the ſame diſtem-

per. Perhaps from hence it happens, that ſometimes an Aſthma is induced by reaſon of the evil of the Ventricle, and that that diſtemper (as *Riverius* obſerves) is often wont to be cured by an emetick Medicine.

After ſo many branches and ſhoots have been ſent from both ſides the wandring pair, at length its Trunk is divided below the Lungs into two branches, *viz.* the exterior and interior; either of which inclining towards the pair of branches on the other ſide, are united to them, and after a mutual communication they conſtitute the two Stomachical branches, *viz.* the ſuperior and the inferior, *Fig. 9 a. a. w. x.*

It is worth obſerving, with what wonderful artifice either Trunk of the wandring pair do communicate one with the other with two branches, as it were two hands meeting one the other, that the influence of either nerve might equally reach to every region and part of the Stomach. For when as either Stomachical branch, to wit, both the upper and the lower, is carried together from the two branches coming out from either ſide of the wandring pair; it is provided, that the Tributes of the Spirits deſtinated to the Ventricle, ſhould be at once certain and very plentiful. For what appertains to the performing the action of this Bowel or Chylification, the Spirits flowing in from either ſide, are abundantly diſtributed into the Oriſice, and from thence into all its parts and private places; and by that means it comes to paſs, that the Stomach diſſolves bodies beyond the force of any Chymical Menſtruum. Then beſides, as to the feeling or ſenſe of the Ventricle, or the affection of it from things ingeſted; it is carried alſo towards the Head by a double way (whereby the paſſage may be the more certain) to wit, by either Trunk of the wandring pair; that for that reaſon being endued with a moſt exquiſite ſenſe, it might not be deceived concerning its objects; and if that any thing inimical or contrary to it, ſhould lye hid among what is eaten, it might diſcern it and thruſt it out of its own accord, or at leaſt by the knowledge only of the Cerebel.

That from the ſame double Trunk of the wandring pair, from whence the Cardiack Nerves ariſe a little above, the Stomachical branches alſo proceed, the cauſe is plain, wherefore the Heart it hath ſuch a Sympathy with the Stomach, ſo that its *Deliquium* or Swooning follows upon any great pulling or hawling of this.

Either Nerve of the wandring pair is terminated in the Ventricle it ſelf: for after the eighth Conjugation hath made as it were an high road for the paſſage of the animal Spirits to the *Præcordia* and to this noble Bowel, it puts a bound to it ſelf; nor indeed does it ſeem meet to have its branches ſtretched out any further to the *Viſcera* of the lower Belly: becauſe it ſeems an unworthy thing, that the ſame path which leads to the chief office of nutrition and to the Palaces of life it ſelf, ſhould lye open to the more vile Inteſtines alſo, and the ſink of the whole Body. And truly, although the ample path and broad way of the wandring pair is not produced beyond the Ventricle; yet becauſe a frequent commerce happens between this and the *Præcordia* and the other inferior parts; therefore between the Stomach and the other Bowels, though of a more baſe uſe, certain Fibres, as it were ſmaller paths, are reached forth, in which, at leaſt little bands of Spirits, like Diſcoverers or Meſſengers, run to and fro.

CHAP. XXV.

A Deſcription of the Intercoſtal Nerve.

After the unfolding of the Nerve reaching forth to the *Præcordia* and the Ventricle, we are led by the ſeries or order of the inward parts to the deſcribing a Nerve a kin to this, and which reaches forth its branches to the furthermoſt Province, to wit, to all the *Viſcera* or Inwards of the lower Belly contained below the Ventricle. This is commonly called the Intercoſtal, becauſe that going near the roots of the Ribs, it receives in every one of their Interſtices a branch from the ſpinal Marrow. Its beginning is not yet ſufficiently detected; for by moſt Anatomiſts it is wrongfully taken for a branch of the wandring pair, though indeed the wandring and the intercoſtal pair do communicate among themſelves by branches ſent forth one to the other; yet as to both their beginnings, Trunks and wandrings up and down, they are plainly diſtinguiſhed. If that this latter Conjugation, being denied the title of a peculiar nerve, ought to confeſs it ſelf of another ſtock, certainly it owes nothing to the wandring pair, but ſhould borrow its original from the Nerves of the fifth and ſixth pairs; for two or three ſhoots being ſent back from thoſe nerves going out towards the Eyes and Face, go into the ſame ſtock or Trunk, which is the Trunk of the intercoſtal nerve, as we have intimated before.

The intercoſtal Nerve being conſtituted after that manner, and going out of the Skull at a proper hole, preſently contains the Ganglioform infolding, Near to another the like infolding of the wandring pair; into which two nervous Proceſſes are carried from the laſt pair within the Skull, or the firſt Vertebral. From that infolding one ſhoot is ſent forth into the Sphincter of the Throat, and another noted one into the Ganglioform infolding of the wandring pair. Then this nerve deſcending towards the

Vertebræ,

Vertebræ, hath in the middle of the Neck another far greater infolding, into which an ample nerve, from the neighbouring Vertebral pair, is inſerted; but from the ſame many nerves, which reſpect the *Præcordia*, are diſtributed on every ſide: For two or three ſhoots are ſent forth into the nerve of the *Diaphragma*, and one ſhoot into the returning nerve; beſides numerous fibres and ſhoots are carried both into the returning nerve, and towards the *Tracbea*, which are inſerted into its Coats, and into thoſe of the *Oeſophagus*, and into the blood-carrying Veſſels. Further, one branch deſcends into the Trunk of the wandring pair, and two noted nerves into the Cardiack infolding; then a little lower another nerve by it ſelf, proceeding out of the intercoſtal Trunk, is inſerted alſo into the Cardiack infolding: which noted branches ſent down on both ſides from the intercoſtal nerve, for that they joyn together with others derived from either Trunk of the wandring pair, make the Cardiack infolding it ſelf. But theſe Cardiack branches from the intercoſtal nerve, as alſo the Cervical infolding, or that in the hinder part of the Neck, whence they proceed, are peculiar to men, and are wholly wanting in brute beaſts.

The intercoſtal Trunk deſcends from the cervical infolding towards the chanel-bone, where being about to enter the cavity of the Breaſt, it falls upon the axillary Artery, as it were in right Angles, and ſtrains or binds it; from whence it is drowned or hidden in the *Thorax* near the roots of the firſt and ſecond Ribs; and there receiving three or four branches from the Vertebral nerves next to thoſe uppermoſt, conſtitutes another infolding, which is commonly called the Intercoſtal infolding. The uppermoſt of theſe Vertebral nerves coming to this infolding in its journey binds the Vertebral Artery, and almoſt compaſſes it about. In Brutes by this nerve which comes upon the Vertebral Artery, the intercoſtal infolding communicates with the root of the nerve of the *Diaphragma*, and not by any other means, unleſs by ſmall fibres ſent forth from the lower part of the infolding into the Vertebral nerves. Further, in Brutes a noted branch is carried from this infolding into the Trunk of the wandring pair. But in Man the intercoſtal Trunk paſſes through the cavity of the *Thorax* without any communication had with the other parts; unleſs that from hence in its whole deſcent, running near the roots of the Ribs, it admits in every one of their interſpaces and from thence even to the *Os ſacrum* from between the knots of the *Vertebræ*, a Vertebral branch.

The intercoſtal pair ſends forth a noted branch on either ſide, where having gone through the cavity of the *Thorax* or Breaſt, it comes over againſt the bottom of the Ventricle, which tending towards the *Meſentery*, conſtitutes the chief infoldings of it. But there are ſeven Meſenterick infoldings, *viz.* five great ſuperior, and two leſs inferior: out of all which, numerous ſhoots and fibres are ſent forth together into the parts which they reſpect, and into the neighbouring infoldings. The Meſenterick nerves, which are carried into theſe infoldings, and the infoldings themſelves, and alſo the fibres and ſhoots, which flow out from them on every ſide, like rays of light, are diſpoſed according to the following manner both in Man and in the more perfect Brutes.

The Meſenterick branch therefore in the left ſide going from the intercoſtal Nerve, and bending downwards, is parted into two noted ſhoots: the greater of theſe bending back upwards towards the Stomach, diffuſeth it ſelf preſently into an infolding, as a narrow rivulet into a ſpacious Pool. From this infolding numerous fibres and ſhoots go forth as it were in four bands. The firſt of theſe, and which is the greateſt bundle of its fibres, being carried into the Ventricle, is beſtowed partly in the bottom of it, and partly theſe fibres are met, and ingraffed with others ſent from the Stomachical branch. The other maniple or band of nervous Fibres goes forth from this infolding to the Spleen, where the nerves accompanying the ſanguiferous Veſſels, and variouſly binding them about, are diſperſed into the more inward frame or ſubſtance of the Spleen; yet out of which going towards the Spleen, ſome ſhoots following the ſhort Veſſels are carried into the Stomach. The third Company of nervous Fibres is inſerted between this infolding, and the Hepatick or that belonging to the Liver, placed in the right ſide over againſt it. Laſtly, the fourth Conjugation of Fibres knits together this and the greateſt infolding of the Meſentery lying under it.

The lower ſhoot of the Meſenterick branch, which is on the left ſide, increaſes into an infolding, to which the next Vertebral branch, deſtinated to the intercoſtal Nerve, is carried. From this infolding the chief bundle of the nervous Fibres is carried into the left Kidney, and before the Fibres enter the Reins, they bind and variouſly compaſs about the emulgent Veſſels. Further, between this infolding and the greateſt of the Meſentery many Fibres are ſtretched out; from hence alſo many ſhoots are diſtributed into the atrabilary Cheſt, or the Receptacle of the Spleens excrements.

In the right ſide the Meſenterick branch being ſent from the intercoſtal Trunk, and being in like manner twofold, contains in its upper ſhoot the Hepatick infolding; out of which the greateſt bundle of nervous Fibres is carried towards the Liver; numerous ſhoots of which accompanying the blood-carrying Veſſels, greatly beſet, and as it were cloath with a little net the Trunk of the Hepatick Artery: which Fibres and ſhoots, being carried higher, are diſtributed into the Liver, Gall cheſt or bag, the paſſage of the Gall, the Pylorus, and the Pancreas. Further, many Fibres, which are of this Conjugation, meet with Fibres ſent from either Stomachical nerve, and are ingraffed into them. Another hand of nervous Fibres is ſtretched out between this infolding and the oppoſite infolding to the Spleen, and another between this and the greateſt infolding of the Meſentery; yea, there is ſome communication had between this and that belonging to the Kidney lying under the ſame ſide by a large ſhoot ſent down.

The lower ſhoot of the right Meſenterick branch, like as it is in the oppoſite ſide, contains a ſufficiently noted infolding nigh the atrabilary Cheſt; to which preſently the intercoſtal Nerve imparts its Vertebral branch received below. From this infolding the chief bundle of nervous Fibres deſtinated to the Reins, embraces the blood-carrying Veſſels in like manner as in the oppoſite ſide; alſo many fibres and ſhoots are ſtretched out from this infolding to thoſe near, *viz.* the Hepatick and the greateſt of the Meſentery; yea, certain Fibres are diſperſed from the ſame into the atrabilary Cheſt.

After this manner either Meſenterick branch being carried from the intercoſtal pair, and being preſently twofold, immediately conſtitutes two infoldings in either ſide. In the midſt of theſe the infolding of all ſtands like the Sun in the midſt of the Planets; from which numerous ſhoots and fibres are diſperſed into all the parts of the Meſentery; which indeed following the blood-carrying Veſſels in their whole proceſs, climb over and bind about the ſame. Moreover, between this infolding and every one of the four aforeſaid is produced a peculiar little bundle of Fibres. Beſides, in the female Sex, from hence ſome ſhoots are carried into the Glandula's of the Womb, commonly called the Stones. But from the Meſenterick branches, which conſtitute the former infoldings, no noted branches, but only little ſhoots, are ſent into this infolding. Yea the chief Nerve which is inſerted to this, and ſeems to be the primary for the coveying of plenty of Spirits into it, and a broad way, is carried from a certain ſmall infolding far lower nigh the ſtraight Inteſtine; which infolding, together with the other neighbouring one, that we call the leſſer infoldings of the Meſentery, ſhall be deſcribed preſently. In the mean time, that we may proceed to them in order, we will follow the paſſage of the intercoſtal Nerve.

Below the Meſenterick branches, from which the aforeſaid ſuperior infoldings are conſtituted, the intercoſtal Trunk deſcends between the Muſcles of the Loyns, and beſtows every Vertebral branch, admitted in its deſcent, upon ſome internal parts.

For the Vertebral branch brought to the intercoſtal Trunk nigh both Kidneys, is carried into the Womens Teſticles, then ſome following into the Ureters. From the Region of the twenty ſeventh *Vertebra* one Vertebral branch and two others, going from the intercoſtal Trunk, tends towards the ſtrait Inteſtine, and there they meet with three pair ſent from the other ſide; all which being united, conſtitute the infolding, which is the loweſt of the Abdomen. From this infolding a noted Nerve, being carried upwards, is brought into the greateſt infolding of the Meſentery, which in its journey receives one and then another ſhoot ſent down on both ſides from the intercoſtal Nerve; and there, near its bounds, diſtributes ſome ſhoots into the Glandula's of the Womb.

But from the loweſt aforeſaidin folding, a Nerve going towards the upper Infoldings, about the ſpace of an inch, conſtitutes another leſſer infolding in the neighbourhood; out of which one Nerve tends upwards, and another oppoſite ſtraight downwards. The former of them is carried into the greateſt infolding of the Meſentery, and in its whole paſſage ſtretches under the ſtraight Inteſtine, and part of the *Colon*, and inſerts into them many ſmall ſhoots. But the other Nerve deſcending from this infolding towards the *Anus* under the inferior part of the ſtraight Inteſtine, imparts to it alſo frequent ſhoots; ſo that this infolding, the leaſt of all thoſe which are within the Abdomen, ſeems to be conſtituted for the ſake of this Nerve only, to wit, which lying under the ſtraight Inteſtine and part of the *Colon*, is inſerted into the greateſt infolding of the Meſentery.

From the loweſt neighbouring Infolding, to which this leaſt owes its original, two Nerves going out, and being ſent down into the *Pelvis*, cauſe there two infoldings, *viz.* one in either ſide, in which the Nerves coming from the *Os ſacrum*, and ingraffed with the former, meet; from which alſo the Nerves diſtributed into the abjacent parts, ſerve unto the ſeveral Excretions, *viz.* of the Urine, Dung, and Seed made in that place: for two Nerves enter into the end of the ſtraight Inteſtine, and as many into the Womb or Proſtates; but one and that noted one, is carried into the Bladder.

But that we may return to the Intercoſtal pair, after either Trunk of it had ſent forth three branches, out of which the aforeſaid lower infoldings of the *Abdomen* are mediately or immediately made, it deſcends ſtraight towards the *Os ſacrum*, and in its journey ſends forth yet one or two branches into the Ureters: but as ſoon as it is come to the beginning of the *Os ſacrum*, both nerves mutually inclining themſelves to one another, are demerged within the bending of the ſame bone, and there nigh its declining, and then in its deſcent, they ſeem to be knit together upon it by two or three proceſſes; and ſo at length either nerve ends in very ſmall fibres, which are diſtributed into the Sphincter of the *Anus*. But ſometimes either nerve joyn together into a round infolding nigh one tranſverſe proceſs, out of which ſingle infolding the like very ſmall Fibres are produced. Further, many others from the laſt Vertebral Nerve meet with, and are ingraffed with theſe Fibres from the intercoſtal pair inſerted into the *Anus*.

CHAP.

CHAP. XXVI.

The Explication of the Intercoſtal Pair of Nerves which are deſcribed in the former Chapter as to their Offices and Uſes: and firſt the upper Branching of them is conſidered.

THE beginning of the Intercoſtal Nerve are two or three ſhoots reflected or turned back from the Nerves of the fifth and ſixth pair, and united into the ſame Trunk, *Fig. 9. D. a. a. b.* Here we may wonder at the birth of this Nerve, as it were borrowed; for it grows as a ſhrub upon another tree or ſhrub; and therefore diſpenſes the common virtues and influences of either with a double branching, *viz.* both its own and that of its parent: by which ramification or branching it comes to paſs, that there are very quick commerces and conſent between the conceptions of the Brain and the affections of the *Præcordia*, alſo between the Actions and Paſſions almoſt of all the parts of the whole Body, which belong to the involuntary Function. For in that the Trunk of the intercoſtal Nerve proceeds from the Nerves of the fifth and ſixth pair nigh their beginnings, that is a ſign that both the influence of the animal Spirits, and the inſtincts for the performing of motions, are derived chiefly into it from the Cerebel; to wit, from whoſe annular proceſs the aforeſaid pairs of Nerves ariſe. But foraſmuch as the ſame intercoſtal Nerve is rooted in their Trunks, and not immediately in the Cerebel; this is the reaſon why the Eyes, as alſo the parts of the Mouth and Face, to which the fifth and ſixth pairs have regard, do anſwer ſo readily and unknown to the Cerebel, as it were by the ſame act, to the motions of the *Præcordia* and *Viſcera*, which the intercoſtal Nerve effects; and on the contrary, the motions of theſe preſently follow the action of thoſe. As for example, in Sneezing as ſoon as the nervous Fibres beſmearing the Noſtrils, are wrinkled together by the pulling, preſently by the paſſage of the intercoſtal nerve the Diaphragma, by reaſon of a more deep inſpiration or drawing in the breath, is for ſome time depreſſed; then the Cramp of the Noſtrils remitting, the Midriff alſo being violently drawn back, cauſes a more ſtrong breathing forth with a vehement blowing of the Air. In like manner on the contrary, when by a tickling made upon the Ribs, the Diaphragma being affected with a Spaſm, moves to a cackling noiſe, the Face and Mouth are pathetically figured with it into laughter.

The intercoſtal Nerve being ſlid out of the Skull, preſently conſtitutes the Ganglioform infolding *Fig. 9. G.* it being after the ſame manner in the Trunk of the wandring pair. What the uſe of theſe infoldings is in general, we have already ſhewn; and clearly for the ſame reaſon in this place in the intercoſtal Trunk, where it receives into it ſelf ſome nerves from elſewhere, and ſends forth others from it ſelf into the neighbouring parts, this infolding, as it were a knot in the ſtem of a flouriſhing Tree, is made, that it may be as it were a diverting place for the manifold tendency of the Spirits. As to the adventitious Nerves it is obſerved, That by them plenty of ſubſidiary Spirits are tranſmitted hither, only from the ſpinal Marrow, but by a manifold and frequent paſſage; wherefore in this infolding, and again in the following, then a little lower, nigh the ſeveral junctures of the *Vertebræ*, the Vertebral branch comes to either Trunk of the intercoſtal pair: this ſeems to be ſo conſtituted for many uſes. Firſt, That the intercoſtal Nerve, by the reiterated faſtening to the ſolid parts, as it were by a frequent ſtay, might become the more firm for the making of a long journey, when otherwiſe its little rope, by too much ſtretching out, might be eaſily broken. Secondly, By this means it comes to paſs, that the nerves which are the Executors of the ſpontaneous, and thoſe of the involuntary Function, might have both a more certain commerce together, and might be ſometimes excited into mutual ſuccors. Hence Reſpiration and ſome other Acts, eſpecially what concerns the Act of *Venus*, participate of either Regiment, ſo that ſometimes they follow the will, and ſometimes draw it even by force or unwilling. Further, when at any time the ſtock of animal Spirits is deficient in either Province, ſupplies of them are ſought from the other: to wit, (as we hinted above) if the influence towards the *Præcordia* be ſhut up through the ordinary paſſages, *viz.* the internal nerves, their paſſages requiſite for the ſuſtaining of life, might be ſupplied by the Vertebral branches: yea it is probable in the partial *Apoplexie*, and in the *Incubus* or Night-mare, when the Cerebel being affected, the Spirits deſtinated for the Heart, ſuffer an Eclipſe in the Fountain it ſelf, that through theſe Emiſſaries, to wit, the Vertebral branches inſerted into the intercoſtal pair, ſome extemporary Subſides are carried for the actuating the Heart. Thirdly, The Vertebral branches by ſo frequent an inſertion, are added to the intercoſtal nerve, perchance in ſome reſpect for this end alſo, that the ſuperfluous or excrementitious humidities, heaped together about the ſpinal Marrow, might be ſent away by theſe Proceſſes: for indeed we have already ſhewn, that a certain humor doth abound within the Head, the medullar Appendix, and nervous Syſtem; which oftentimes (when it becomes watry, or abounds above meaſure) begets a ſerous heap in thoſe parts: wherefore when the branches of the intercoſtal nerve are terminated into the Meſentery, Kidneys, Inteſtines, and ſome Genital parts, it is probable they do tranſfer into theſe ſinks ſuperfluous humidites, not only their own, but alſo of another ſort, to wit, thoſe received from the ſpinal Nerves.

As

As to the Nerves, which as Emiſſaries, are carried from the aforeſaid Ganglioform infolding into other parts, we obſerve; firſt, that a noted ſhoot is carried from hence into the Sphincter of the Throat, *Fig.* 9. γ. This nerve in the Sphincter of the Throat correſponds with others akin, ariſing higher from the fifth pair, and diſtributed into the parts of the Palate and Mouth, and is helpful to them in the buſineſs of chewing: for when the maxillar branches of the fifth pair ſhould perform their work for the chewing of the food taken in, the task of this nerve mediately ariſing alſo from the fifth pair, follows to wit, whereby the Throat being opened, the chewed meats may be thruſt forward into its paſſage.

Another ſhoot is ſtretched out from this infolding into a like infolding of the wandring pair placed near, *Fig.* 9. α. The reaſon of this inſertion is delivered above, where we treat of the wandring Pair. But it may be obſerved further concerning this; when ſo nigh a communication happens between theſe infoldings, and when ſhoots are ſent from one of them into the Muſcles of the *Larynx*, and from another into the Muſcles of the Throat, from hence we may give a reaſon, why in Hyſterick diſtempers and in ſome Hypochondriacal, here is ſo frequent and familiar a Symptom of the ſenſe of choaking in the Throat. For a Cramp or Convulſion being begun in any Nerve, it is wont to creep forward further by the paſſage of the ſame, and ſo to invade ſometimes theſe parts, ſometimes thoſe ſucceſſively. If therefore at any time a Spaſm ariſes any where in any nerve of the wandring or intercoſtal pair, and from thence tending upwards or downwards, ſhall come to either infolding, preſently both being affected, and the Muſcles of the whole neighbourhood being contracted, a bulk or Tumor like a Globe or round thing in the Throat is excited with a ſenſe of choaking,

The intercoſtal Nerve deſcending a little lower, contains in the neck another greater infolding proper to man, to which a noted Vertebral nerve is inſerted alſo, out of which many nerves deſtinated to the *Præcordia*, are ſent forth on either ſide, *Fig.* 9. *T*. As to the principle parts, to wit, the Brain and Heart, there is no ſuch great difference between a Man and a Brute, as there is about the paſſage of one to the other, or the commerce that thoſe parts have mutually among themſelves. In either kind, for the exerciſe of the vital Function, the animal Spirits are derived from the Head, with a conſtant emanation into the Heart; to which ſort of influence of theirs the paſſage of the wandring pair of nerves ſeems ſufficient: wherefore in moſt Brutes the paſſage to the Heart and its Appendix lyes open only by this way, and ſcarce at all by any nerves of the intercoſtal pair. But in Man the intercoſtal nerve, beſides its offices in the lower Belly, common to him with other Animals, ſerves in the place of a ſpecial Internuncius alſo before the Cloiſter of the Breaſt, which bears the mutual ſenſes of the Brain and Heart this way and that way, or to and fro. For when, beſides the nerves of the wandring pair, ſtretched out alſo into the humane *Præcordia*, (which certainly ſeems ſufficient for the executing of the offices of the Function merely vital) ſo many noted branches are ſent forth from the aforeſaid intercoſtal infolding, what kind of office ſhould be attributed to theſe, unleſs that they ſhould contain the animal Spirits, by whoſe work and miniſtry, the mutual reſpects and affections of the Brain and Heart ſhould be communicated to one another? Whilſt I conſider this difference of either kind, it comes into my mind, that Brutes are like Machines framed with a more ſimple furniture and with leſs workmanſhip, and therefore furniſhed with a motion of one kind only, or determined for the doing ſtill the ſame thing. But in Man divers ſeries of motions, and as it were complications of wheels within wheels, appear. For indeed, by the paſſage of the aforeſaid infolding, the conceptions of the Brain preſently affect the Heart and its Veſſel, and cauſe the reſt of the Appendix, together with the Diaphragma, to be moved. Hence the motion of the blood and its inkindling in the Heart, together with the Pulſe and Reſpiration, are altered: and for that cauſe, from the Heart being altered, not only impreſſions are retorted upon the Brain by the paſſage of the ſame nerves, but alſo the blood it ſelf, its courſe being changed, drives to the Brain with a different or unaccuſtomed fluctuation, and ſo by moving the animal Spirits with various impulſes, cauſes firſt one ſort of conceptions, and then others to be produced: and ſo by reaſon of theſe reciprocal affections of the Heart and Brain, which are wont by a long ſeries to be propagated viciſſively, a multiplicity of thoughts and Phantaſms ariſes. Hence both the ancient Divines and Philoſophers placed wiſdom in the Heart. Certainly the Works of Prudence and Vertue depend very much on the mutual commerce which happens to the Heart with the Brain: becauſe, that cogitations about the acts of the Appetite or Judgment may be rightly deſcribed, it is behoveful for the flood of the blood to be reſtrained in the Breaſt, and the inordinations of it and of the Heart it ſelf to be governed by the Nerves, as it were by Reins, and to be compoſed into requiſite and apt motions. We might ſay more concerning this, but that this Speculation is from our purpoſe, and belongs more properly to Pathology or the Doctrine of the Paſſions of the Soul, in the mean time, we may refer hither one or two Obſervations taken from *Anatomy*.

When of late we had diſſected the Carcaſs of a man that was a Fool from his birth, we could find no defect or fault in the Brain, unleſs that its ſubſtance or bulk was very ſmall. But the chief note of difference which we obſerved between the parts of this man and of a man of judgment, was this, That the aforeſaid infolding of the intercoſtal Nerve, which we call the *Internuncius* of the Brain and Heart, proper to man, was very ſmall in this Fool, and beſet with a weaker guard of Nerves,

Whilſt we were writing theſe, we made an Anatomy of a Monkey, whoſe Brain differed little from that which is ſeen in a Dog or a Fox, unleſs that it was much more capacious in the proportion to the bulk of his Body, and the turnings and windings of it were larger. The orbicular Prominences called

Nates

Nates and *Teſtes*, alſo the ringy Protuberance, ſent down from the Cerebel, came nearer the figure and magnitude of thoſe parts in a man. But what occurred chiefly worthy noting, was this, *viz.* That the intercoſtal Nerve, although even as it is wont to be in other Brutes, being included in the ſame ſheath with the Trunk of the eighth pair, was carried through the Neck, yet departing from this Nerve near the Chanel-bone, before it was inſerted into the infolding, placed nigh the roots of the upper Ribs, did ſend forth ſome ſhoots into the Heart and its Appendix, and certain Fibres into the nerve of the Diaphragma: which perhaps partly is the reaſon, why this Animal is ſo craſty and mimical above other Beaſts, and can ſo aptly ſhew and imitate, not only the geſtures, but the paſſions and ſome manners of a man: But we will proceed to the explication of the intercoſtal Nerve from whence we have digreſſed.

We have already intimated for what uſe the Vertebral branch is inſerted into its cervical infolding. There is the ſame reaſon for this as for the other Vertebrals, which communicate with the intercoſtal Nerve almoſt in its whole paſſage. But for that the nerve of the *Diaphragma* is radicated in the ſame Vertebral nerve, from whence a branch comes into this infolding, I ſay from that a reaſon may be taken, why the motion of the *Diaphragma* intimately conſpires with the *Præcordia*, yea and with the conceptions of the Brain: which kind of Sympathy of the *Diaphragma* with the other parts, becauſe it is requiſite to be more ſtrict and noted in man, it is obſerved, That not only the Vertebral branch cometh between the infolding and the root of the nerve of the *Diaphragma*, but two and ſometimes three nerves are ſent from this infolding into the trunk it ſelf of the nerve of the *Diaphragma*, *Fig.* 9. ε. ε. Truly from hence not only the joynt action or *Sympraxis* of the *Diaphragma* with the *Præcordia* may be derived; but alſo the genuine cauſe is here manifeſt, why Riſibility is a proper Affection of a man. For as often as the Imagination is affected by any pleaſant or wonderful conception, preſently the Heart deſires to rejoyce, and as it were by ſhaking off its load to be eaſed: wherefore that the blood might be more ſwiftly emptied out of its right boſom into the Lungs, and conſequently out of the left into the *Aorta*, the *Diaphragma*, inſtigated by the paſſage of the nerves going out of this infolding, is drawn upward by a more rapid *Syſtole*, and raiſes up the Lungs, as it were making iterated leaps, and cauſes them, by their more frequent ſtriking together, to drive out both the Air and the blood. Then foraſmuch as the ſame Intercoſtal Nerve, which communicates lower with the nerve of the *Diaphragma*, is continued alſo higher with the maxillary Nerves, a cackling being made in the Breaſt, with it the geſture of the Mouth and Face pathetically anſwers.

One or two noted ſhoots and many nervous Fibres are carried from this infolding into the returning Nerve, *Fig.* 9. ζ. Certainly the reaſon of this communication ſeems to be, that the *Diaphragma* and the Heart it ſelf (into which nerves are ſent from this infolding) might yet more conſpire with the rough Artery (which the returning nerve affects) in its various actions, and eſpecially in laughing, weeping, and ſinging. Moreover, when the returning Nerves, by pulling upwards the Trunks of the *Aorta*, cauſe the blood, for the ſtiring up ſome Affections, to creep more ſwiftly towards the Head, they may in the performing that office be much helped by the aſſociate labour of the Nerves ſent from this infolding.

From this infolding in the Neck many ſmall fibres and ſhoots are ſpread into the ſanguiferous Veſſels, as alſo into the Coats of the *Trachea* and the *Oeſophagus*, *Fig.* 9. *ibid.* As to what belongs to the former that reſpect the *Trachea* and the blood carrying Veſſels; their office is, that they may reſpectively draw together and ſpread abroad thoſe channels of inſpired and expired blood and Air, according to the way and manner wherewith the Pulſe and Breathing ought to be performed; whereby the motions of either might be the better retarded or accelerated, according to the neceſſities or requirings of the Heart. Then numerous Fibres are ſtretched out from this infolding into the Coats of the *Oeſophagus* placed near, that by this means the admirable conſent between the Heart and the Stomach, by reaſon of the Nerves being reached forth from this infolding and from the wandring pair to both, may be produced.

Concerning the Cardiack branches ſent from this infolding, we need not diſcourſe any more: after having but now intimated, that theſe were as it were *Internuncii* peculiar to men, which carrying to and fro the reciprocal impreſſions of the Brain and Heart, cauſe Commerces in both Kingdoms. But foraſmuch as Nerves of a double kind, *viz.* of the wandring and intercoſtal pair, reſpect the humane *Præcordia*, leſt the geſtures of one ſhould be different from thoſe of the other, therefore the *Cardiack* branches, which are of either family, partly communicate in the ſame infolding, and are partly inoculated mutually by ſhoots ſent forth before they are diſtributed into the Heart it ſelf.

Below the Cervical infolding, the intercoſtal Trunk being demerſed within the *Thorax*, admits three Vertebral Nerves ariſing higher, and conſtitutes the other infolding, which is commonly called the Intercoſtal, but more properly the *Thoracical* infolding, *Fig.* 9. θ. In this place the intercoſtal Nerve being about to paſs into its laſt and more large Province, *viz.* the *Viſcera* of the lower Belly, and therefore ſeeking aid for the journey, and as it were a *Viaticum* for it ſelf, it gets together in this infolding an increaſe or aiding forces from the Vertebral nerves, and afterwards receives lower others freſh nigh the ſeveral knots of the *Vertebræ*; becauſe it will have need of a great ſtock of the Spirits, which it muſt beſtow on the Meſenterick infoldings, and on other parts of the *Abdomen*.

That

That this Nerve about to enter the Thoracical infolding, doth bind the Chanel-bone Artery, *Fig. 9. l.* and that the ſuperior branch of the Vertebral, being ſent into the ſame infolding, doth bind about the Vertebral Artery, *Fig. 9. r.* the reaſon of both ſeems, that the blood, for the uſes and neceſſities of the lower *Viſcera* (to which the intercoſtal Nerve from thence ſerves) may be driven forward with a more plentiful afflux downwards: which thing thoſe Nerves eaſily do by pulling together the blood-carrying Veſſels towards their infolding; ſo that they attempt this ſnatching of the blood in oppoſition to that which the returning Nerves perform. And indeed when the blood, tending upwards and downwards is wont ſometimes to flow too much towards either bound, ſometimes to be wanting; therefore the nerves, as it were an incitement or remora, are variouſly diſpoſed both in the upper and lower region of the Circuit about the ſanguiferous Veſſels. After what manner this Thoracical infolding is in brute Beaſts, ſhall be particularly ſhewn hereafter. The intercoſtal Nerve in a Man, both in this infolding and in the whole deſcent through the *Thorax*, receives many Vertebral nerves, as if ſparing of its own ſtock, and greedy of anothers, but ſends forth from it ſelf not a ſhoot: whatever of Spirits is remaining either from the influence above, or comes to it by the by, is reſerved wholly for a largeſs to be beſtowed on the *Viſcera* of the lower Belly. But after what manner, and by what paſſages of nerves that is diſpenſed into the ſeveral parts, we will unfold in the following Chapter.

CHAP. XXVII.

The lower Branching of the Intercoſtal Nerve belonging to the Parts and Viſcera *of the lower Belly is unfolded.*

AFter the intercoſtal Pair hath paſt through the hollowneſs of the *Thorax* without any expence of Spirits, unleſs in the Neck-infolding, at length it ſends down from the region of the Ventricle on both ſides, a noted Branch; either of which preſently becoming divided into two, conſtitute two peculiar Infoldings on either ſide; but one infolding ariſes in the midſt of them, as if common to either ſide. Of the infoldings which are on the left ſide, one reſpects the Kidney, and the other the Ventricle with the Spleen; but of thoſe which are on the oppoſite ſide, one reſpects the right Kidney, and the other the Liver and its neighbouring part. In the midſt of theſe, the infolding proper to the *Meſentery* and the biggeſt, is placed as the Sun among the other *Planets*. Further, from theſe are ſent forth one to another and into the neighbouring parts numerous Fibres very thickly, as it were dartings of rays. *Fig.* 11. plainly ſhews all theſe.

Concerning theſe, in the firſt place, it ſhall be inquired into in general, For what end ſo many nervous infoldings, with almoſt innumerable fibres and ſhoots, are diſtributed about the Meſentery and the *Viſcera* of the *Abdomen*. For when in theſe parts the fibres and nervous ſhoots are carried on every ſide with ſo thick a ſeries, that they are variouſly infolded with their manifold meeting, it may ſeem wonderful, if every one of theſe be deſtinated to ſome uſes, and are not rather ſprinkled here and there by chance, and as it were by the inconſiderate ſporting of Nature. And indeed any one can ſcarce think, that ſo many Veſſels ſhould be prepared for the performing the offices of motion or ſenſe in that place. For thoſe *Viſcera*, unleſs highly pulled and affected with a Convulſion, are ſenſible of little or nothing that we know of; and their motions are almoſt no other thing than obſcure Vermiculations or light Corrugations, ſo that for the effecting them there is required no greater preparation than for the ſlow progreſs of a Snail.

Wherefore from hence it hath come into the mind of ſome, that a certain Juyce, and that perhaps nutritious, was diſpenſed by this manifold paſſage of the nervous Pipes: which ſort of office however, if aſſigned to theſe Fibres diſperſed about the Meſentery, why ſhould not the ſame office either of receiving or of carrying of nouriſhment, be granted to thoſe in like manner divaricated about the Lungs and the *Præcordia*, and eſpecially about the rough *Artery*? But truly it is highly improbable, that a nutritious Juyce ſhould be contained in the Coats of the *Trachea* or of the *Bronchia*, which the nerves may ſuck out; nor does it more clearly appear, why more nerves ſhould be deſtinated for the carrying of the alible Juyce to theſe parts of the Abdomen, or thoſe of the Breaſt, than is needful for the muſculous ſtock. But in the mean time, though we deny, that the whole nutritious matter is carried this way and that way by thoſe or the other nerves; yet we think, that within thoſe nervous paſſages an humor doth perpetually abound, which may be for a Vehicle of the animal Spirits, and a Ferment for the nutritious matter: with which going with the nervous humor towards the Inteſtines and to the other ſinks of the Body, it is likely, that the ſuperfluous and excrementitious ſeroſities do often ſlide down together, and ſo are carried out.

But

But it may be well thought, as to the Meſenterick Nerves, and Infoldings in which they are terminated, and the Fibres moſt thickly going out of theſe, that theſe different manner of Veſſels are firſt Chanels, then Storehouſes, and laſtly the laſt Emiſſaries of the animal Spirits. If it ſhould be demanded, for what end ſo great plenty of Spirits ſhould be deſigned for theſe ignobler parts; I ſay, that this is done for the performing the acts of Motion and Senſe there, which are highly neceſſary for the preſerving of life it ſelf. For although local motion, which is always performed by the help of a Muſcle, as of a Spring, is not convenient for the *Viſcera* of the lower Belly; yet inteſtine motions are brought forth by them almoſt continually, and after many faſhions: *viz.* for the ſubduing the Chyle, alſo for the ſeparation of ſome parts and particles from others, both of that, and alſo of the bloody Liquor, and the protruſion of every one towards their deſigned bounds, the Fibres and nervous ſhoots reaching into the Membranes of the *Viſcera* and the Coats of the Veſſels, yea and into the textures of the *Parenchyma*, are variouſly drawn together, to wit, theſe are pulled upwards, thoſe downwards; ſometimes many together, ſometimes apart or ſucceſſively, are wont to be drawn hither and thither. In truth, it is a ſign of the indiſcontinued action of theſe *Viſcera*, that as well in ſleep, and perhaps more than in waking, the Culinary work of Nutrition is performed; and whilſt the Organs of the other Faculties are at reſt, there is no quiet granted to theſe: but that the Meſenterick nerves perpetually grinding in the Mill, are always buſied for the preparing the alible humor and the exporting the ſame towards all parts.

Moreover in theſe parts, to which the aforeſaid Nerves belong, there is found an exquiſite feeling no leſs than a motive Faculty; for whatſoever heterogeneous or hurtful thing, mixed with the Chyle or blood, is brought to any *Viſcera*, preſently the Spirits, inhabiting thoſe parts, being warned of the evil, do greatly tumultuate as it were by entring into a Conſpiracy, that what is hoſtile or troubleſom they might ſhut out. But indeed, becauſe the animal Spirits, flowing by the paſſage of the intercoſtal nerve to the Inteſtines and *Viſcera* akin to them, proceed from the Cerebel; therefore the buſineſſes of either Faculty, to wit, both the ſenſitive and locomotive, foraſmuch as they are performed the Brain unconſulted, and the animal ſcarce knowing it, are not ſo openly taken notice of, and for that reaſon they are accounted of leſs than the ſpontaneous acts of the other parts.

But as to the manner it ſelf or way of the œconomy, whereby the animal Spirits, deſtinated to the *Viſcera* of the lower Belly, are exerciſed, we affirm, That plenty of them flow into all the Meſenterick infoldings by the paſſage of the nerves ſent from the intercoſtal pair; where being heaped up to a fulneſs, as it were in ſo many Storehouſes or places of Receipt, they are kept to be diſtributed from thence into ſeveral parts, as occaſion requires. But that the Spirits flow out of theſe infoldings, not through ſingular and larger branches, (as is done in the Muſcles) but as it were by Troops of Fibres, into their proper tasks, the reaſon is, becauſe here the buſines is performed otherwiſe than in the muſculous ſtock. For where a Muſcle is fixed to the part to be moved, its implanted Fibres perform the whole work of Contraction, or of the motive endeavour; but it ſuffices for the nerve ſtill to convey new ſupplements of Spirits, and as occaſion ſerves, the Inſtincts of the Motion to be performed: but in the Membranes and the *Viſcera*, where Muſcles are wanting, the nervous Fibres themſelves moſt thickly implanted, and diſtributed as it were ſo many little ropes, almoſt into every part of the ſubject, perform the buſineſs of Traction or drawing by themſelves and their own proper endeavour or force partly; and partly ſolicite or ſtir up into motion the Fibres implanted in the *Viſcera* diſpoſed after an uncertain order; which they determinate in their action, and moderate or govern them, as it were ſo many fingers laid upon the ſtrings of a muſical Inſtrument. For although the Membranes and the *Viſcera* themſelves are indued with ſome implanted Fibres; yet theſe are not, as it is in the Muſcles, of one kind and poſition; but in the ſame part ſome are ſtraight, and others oblique or crooked, theſe tend upwards, thoſe downwards, and others are carried round; ſo that divers ſorts of motions ought to be performed in the ſame Membrane or Inward, ſometimes together, ſometimes ſucceſſively or by turns: wherefore diſtinct nerves are required, not only for the ſeveral ſeries of Fibres, but for all the parts of the ſubject, to wit, which may ſtop here a motion begun in that place, and may begin another anew, or may unite one with another. Truly the motion which is performed in the muſculous ſtock ſeems like the rude and more ſimple work of ſome Weaver, where the ſhuttle being always caſt after the ſame manner, the Woof is laid under the Thread or Yarn: but the motions of the Inteſtines and *Viſcera* may be aptly compared to a Texture very much variegated or flouriſhed, for the weaving of whoſe more artificial ſubſtance or making there is made uſe of many hands together, or of a Machine diverſly turning about, and furniſhed with more than a thouſand ſorts of motions.

Concerning the many Meſenterick Nerves, and Shoots, and nervous Fibres which go out of them by bands, we muſt conſider chiefly theſe two things: to wit, what may be the office of each of them for the ſtirring up of motion or ſenſe, either of them, or both together in any part: then ſecondly, what the communication of either of them may be with other nerves, infoldings or bundles of nerves, by reaſon of which a Sympathy or conſent of actions ariſes at once in divers parts. According to theſe two reſpects we will particularly weigh now the ſeveral nervous Veſſels belonging to the *Viſcera* of the lower Belly.

Therefore in the left ſide the ſupreme Meſenterick branch being preſently forked like the figure of the Letter Y, contains in its upper ſhoot the Stomachical infolding, which is alſo the Splenetick, and in the other lower the Renal infolding or that belonging to the Reins. Moreover, about

the knot of diviſion it ſends forth ſome ſhoots to the greateſt infolding of the Meſentery, *Fig.* 11. *F. G.* Hence a reaſon is plain, wherefore there happens ſuch affinity between the Ventricle and the Spleen, and between the Meſentery and the Reins, ſo that the very often and familiar Symptom of Vomiting is both in Splenetick, Colical, and Nephritick people: becauſe when a Convulſion is begun in any part or Inward, which the Meſenterick nerve reſpects, preſently other parts, to which the infoldings or ſhoots of the ſame nerve belong, are drawn into conſent.

From this lower infolding a little bundle of Nerves being carried towards the Stomach, inſerts its Fibres partly in its bottom, and partly ſends them to meet with other Fibres ſent down from the nerve of the Stomach, *Fig.* 11. *n.* The reaſon of the former is, That whereas there are many Coats of the Ventricle, and divers ſeries of Fibres are diſpoſed in them, for the actuating all of which with a due influx of animal Spirits, the Stomachical nerves, derived from the wandring pair, are not ſufficient; it was fit, that for the outward Court as it were or Precinct of this Inward, to wit, for the outmoſt bottom of it, ſome forces of Spirits might be ſupplied from ſome ſtrange Kingdom, to wit, from the aforeſaid nervous infolding of the Abdomen. Inſtead of this, Spirits alſo may ſlide downwards from the ſame Stomachical branch through other Fibres ſent down, and be ſent into this Splenetick infolding. Beſides alſo it is obſerved, That the adventitious nerves aptly conſpire with the former, being of the proper dominion of the Ventricle, and that either are not only inoculated within the confines of the Inward it ſelf, but they run into mutual embraces without it, and as it were joyn hands together.

It ſeems plain, that the nervous Filaments being carried from the aforeſaid infolding to the bottom of the Ventricle, may ſerve there for the performing the acts of Motion and Senſation: but it doth not ſo eaſily appear with what office the other handful of Fibres reaching out from hence into the Spleen is charged (*Fig.* 11. *ζ.*) becauſe this Inward is ſaid to be deſtitute wholly of every animal Faculty. When we did elſewhere inquire into the uſe of the Spleen, we thought good to affirm, That its office was to ſeparate the dregs of the Blood and the acid-ſaline Particles, and whatſoever were of a more fixed nature, and to concoct them more being received into its own boſom, and to convert them into an acid Ferment; by which being again delivered to the blood through the Veins, a ſharpneſs and an aſperity, as alſo an active or fermentative virtue are gotten for its *Latex*. Wherefore the whole ſubſtance of the Spleen conſiſts of a texture of Fibres in the form of a net; to wit, that the Feculencies of the blood migh be more plentifully received, and contained within its ſpongy cavities and thick paſſages. I ſay therefore, that for the fit preſerving and diſpenſing of the Splenetick Ferment, beſides the Arteries which carry matter, and the Veins which continually ſup back ſome portion of the ſame fermented, there ſeems to be need of many nerves alſo, which both by pulling the fibrous texture of the Spleen, might cauſe the melancholick and dark *Fæces*, laid up in it, to be ſhaken together, and ſo by defending it from putrefaction and coagulation, cauſe it to be imbued with an acid and fermentative nature; and alſo that thoſe nerves may ſometimes draw together and conſtrain the blood-carrying Veſſels, ſometimes open and inlarge them; that as occaſion ſerves, the Feculencies of the blood may be ſometimes more plentifully, ſometimes more ſparingly laid aſide out of the Arteries into the Spleen; alſo that more or leſs of the Ferment, preſerved in the Spleen, may be poured out on the blood according to the requirings of the Paſſions or of the natural Inſtinct. No Hypochondriack but doth abundantly perceive, that ſome Splenetick nerves do perform motions; for thoſe great perturbations which are wont to be excited in the left ſide, as when ſometimes Inflations, ſometimes conſtrictions of the inward parts, and ſometimes various concuſſions are perceived with a wandring pain running here and there, they are only Spaſms or Convulſions or wrinklings together, with which the nerves of the Spleen are ordinarily affected. Nor do its nerves, taken with a Convulſivon, ſtir up tumults only in the neighbourhood of the Spleen, but oftentimes further into the Heart it ſelf, yea into the whole Body the effects of their inordinations are carried. I have known an Hypochondriack, who preſently upon the Spleen being diſturbed, ſeemed to have his *Præcordia*, being drawn downwards, to be cruelly preſt and bound together; ſo that being very ſad and dejected in his mind, alſo complaining of an exceeding great ſtraitneſs and conſtriction of his Breaſt, he thought himſelf almoſt dead. The cauſe of which kind of diſtemper was without doubt, that when many Fibres going out of the Splenetick infolding are united with the other Fibres ſent from the fartheſt end of the wandring pair, it eaſily happens, that the former, being diſtempered with the Convulſion, do draw together and pull downwards their yokefellows, and by conſequence the Trunk it ſelf of the wandring pair, from which the nerves are ſent into the *Præcordia*: certainly by the *Sympraxis* or joynt action of either kind of the aforeſaid nerves, *viz.* whereof theſe reſpect the Spleen, thoſe the *Præcordia*, it is effected, that the Trembling Oppreſſion, and other grievous Diſtempers of the Heart, as alſo of the Spleen, ſo ordinarily happen. Further, foraſmuch as the Fermentation of the blood depends on the Spleen, according to the influence of this, that perform its Circulation, ſometimes pleaſantly, ſometimes diſturbedly. Whilſt the Spleen is at quiet, and free from any perturbation, the blood alſo is quietly moved in Hypochondriacal perſons; but if the ſame be moved and exerciſed, (as it is wont to be in any paſſion or violent motion of the Body, or by a Medicine) preſently its nerves being diſtempered with a Convulſion, ſhake it more with reiterated contractions; ſo that the fermentative Feculencies, being ſhaken out of its boſom, flow back more plentifully into the blood, which cauſe its *Latex* preſently to be troubled, and as it were muddy, and ſharpen it with ſo great acrimony and mordacity, that it burns and pricks the Brain and Heart like needles; from whence in Splenetick people beſides that the Reaſon is obſcured, the affections of the Mind, eſpecially Sadneſs, Hatred, and Anger are very much increaſed.

Concern-

Concerning the Splenetick Nerves, by another conjecture, we are yet brought to believe, that they, beſides the exerciſe of the motive Faculty, do both inſtil into the Spleen its own humor, which promotes the fermentative virtue of that Inward; and alſo (becauſe the nerves, as was ſhewn already, convey the Spirits, and ſometimes the humors by either way, *viz.* forward and backward) the ſame implanted in the Spleen, do often imbibe from it an acetous or Vinegar-like humor, and as it were Vitriolick, from whoſe acrimony and notable twitching, they are forced into Convulſions.

But foraſmuch as the nervous Infolding reſpecting the Spleen, communicates more nearly with the Ventricle, Meſentery, Liver, and Kidneys, and more remotely with the *Præcordia* and other parts placed at a diſtance; from hence the cauſe is plain, wherefore not only theſe ſeveral *Viſcera* and parts, by reaſon of the fault of the Spleen, are folded together; but alſo on the contrary, why the Spleen being indiſpoſed by any Diſeaſe, or trouble raiſed up in any of thoſe parts, is wont to be diſturbed: ſo it is not altogether for nothing, that the Symptoms every where infeſting, the cauſe of them being unknown, are aſcribed ordinarily to the Spleen; becauſe it fixes not only its own inordinations in other parts, but alſo ſuffers for their peculiar faults: which notwithſtanding is wrongfully aſcribed to Vapours tranſmitted from this or that part, when the formal reaſon of every Diſtemper of this kind for the moſt part conſiſts in the communication made through the Nerves.

The lower Infolding of the left ſide ſeems to be made for the Kidney placed near, into which chiefly the bundle of its Fibres is carried, *Fig.* 11. ♑. γ. γ. Certainly that theſe nerves, following the emulgent Veſſels, do embrace the ſame, and bind them about with a various and frequent complication; that is ſo made for that end, that by reaſon of the Artery being ſo ſtrained and frequently ſhaken by the drawings of the nerves, the Serum may the more eaſily be precipitated from the blood: wherefore it is obſerved in very great difficulty or danger, when the mind and all the nerves are ſtrained for fear, that a frequent and more plentiful making of water, and that often painful, is wont to be provoked.

The Renal Infolding receives, beſides the Nerve common to it with the upper infolding, another new and peculiar one from the intercoſtal nerve, or rather that coming between from the ſpinal Marrow, *Fig.* 11. β. Hence it is, that the Loyns have a great conſent with the Reins, and ſuffer ſo ordinarily for their Diſtempers with a grievous and largely diffuſive pain. Foraſmuch as this infolding communicates with the greateſt of the Meſentery, the Colick diſtemper and the Nephritick are much akin, and it is often difficult to diſtinguiſh their fits one from the other.

The Meſenterick branch in the right ſide, as well as the left, being forked, contains two infoldings: the upper of theſe (which we call the Hepatick) ſends forth from it ſelf many little bundles of nervous Fibres; the greateſt of which being carried towards the Liver, cloaths the Hepatick Artery as it were with a Net made of Fibres, *Fig.* 11. δ. ο. The moſt Learned *Gliſſon* obſerves, That the Hepatick Artery is beſtowed on the Trunks of the Veſſels, to wit, of the common Cheſt, of the bilary Pore, and of the *Vena Porta*; for the watering of which, and for the actuating them with heat and nouriſhing Juyce, it carries the arterious Blood; to which notwithſtanding for the recarrying, an aſſociate Vein is wholly wanting: wherefore that ought to carry the blood, not with a full and free influx, but by little and little, and always in a conſtant meaſure to thoſe membranaceous parts: for otherwiſe there had been danger, leſt from the bloody *Latex* plentifully ruſhing forward, for that it could not be ſtill remanded preſently through the Veins, an Inflammation ſhould be excited, or leſt from its torrent being tranſfuſed beyond its bands, the courſes of the other rivers in the Liver ſhould be diſturbed. But for that the nerves, like Reins, do bind about the Trunk of the Artery, the inflowing of the blood it ſelf is moderated, and they cauſe it variouſly to be diſpenſed according to the wants of thoſe parts to which it is deſtinated.

From the Troop of Nerves going out towards the Liver, ſome bend down into the *Pancreas*, and others into the *Cholidock* Veſſels, *Duodenum*, and *Pylorus*, and ſow into them thick ſeries of ſhoots, *Fig.* 11. π. π. The office of theſe ſeems to be, to pull together the excretory paſſages of thoſe parts, and to ſhake them for the cauſing Evacuations of the boiling or turging humors upon occaſion. Further, from theſe Fibres being carried upwards, when many others ſent from either Stomachical nerve are united, the reaſon is plain, why from an hawling or pulling made about the Ventricle, the yellow Bile is drawn out of the Gall-cheſt into the *Duodenum*, which being carried from thence into the Ventricle, by reaſon of a Convulſion of that ſame Inteſtine, is caſt up by Vomit: becauſe the Stomachical nerves being irritated by a Medicine, or by any troubleſom thing, for the making an Evacuation above, and for that cauſe drawn from thence upwards, they draw together the nerves belonging to the Liver and the *Cholidock* Veſſels, for that they are tied to them, and bring them into conſent with the ſuperior Spaſm or Convulſion. Hence it happens, that not only the Stomach being firſt tired, draws to it ſelf the Bile by its Convulſion, and allures it into its own boſom; but the Bile alſo of its own accord growing turgid, and ſo being poured out into the *Duodenum*, foraſmuch as it irritates the nerves of this Inteſtine, and then by their conſent, provokes the nervous Veſſels of the Ventricle, it preſently induces a cholerick Vomiting.

The Hepatick Infolding communicates with the Splenetick by Fibres going between either, *Fig.* 11. θ. The reaſon of which ſeems to be, That when one infolding reſpects the end or the right extremity of the Ventricle, and another the left; that a conſent in either and a joynt action may be made towards the Stomach, both communicate between themſelves by nerves, as if *Intermuntii*. Truly it ſeems to come to paſs by the paſſage of theſe nerves, that the *Hypochondriacal* pains oftentimes run from the left ſide

nto the right; to wit, for that a Spaſm or Convulſion begun in the Splenetick infolding, is wont to be carried to the Hepatick.

Between the *Hepatick* Infolding and the greateſt of the *Meſentery*, many Fibres reaching out by bands, are caſt out in the midſt, *Fig.* 11. *p. p.* the office of which is to ſuſtain a certain commerce and Sympathy; to wit, ſuch an one is required, both that the Chyle may be miniſtred from the Inteſtines towards the Liver ſtill in due proportion, alſo that the Bile may opportunely ſlide out from the Gall-bladder into the Inteſtines for the provoking of Excretion. For we are of this Opinion, That the Meſeraick Veins ſucking out a certain portion of the Chyle from the Inteſtines, immediately transfer it through the region of the Liver into the *Vena Cava*, whereby the blood in the aſcending Trunk of the hollow Vein or *Vena Cava*, might be freſhly imbued with nouriſhing Juyce; even as in its deſcending Trunk it is refreſhed, the ſame being poured out through the *Thoracical* Veſſels or thoſe belonging to the *Thorax*. Wherefore it is needful, that there ſhould be a very ſtrict affinity between theſe *Viſcera*; and the rather, becauſe the Bile ought to be poured out from the Gall cheſt to the Inteſtines, not continually, but for ſome uſes, by occaſions and intervals. For the Nerves knowing beſt the wants of either part, warn them both of their mutual duty, and as occaſion ſerves, ſtir them into action.

It is obſerved, That in the right ſide an ample Nerve is ſtretched out between the *Hepatick* and *Renal* infolding, *Fig.* 11. *μ.* So that between theſe infoldings a greater and more immediate conſent is had, than between thoſe pairs of the other ſide. The reaſon of which doth not eaſily appear, unleſs perhaps it ſhould be ſo made for this end, that when from the Reins, in making of water, there is an endeavour of the ſerous Excretion, the *Pylorus* and the *Cholidock* Veſſels being at once drawn downwards, a protruſion of the Chyle and *Fæces* might be provoked towards the lower parts of the Belly. Certainly this connexion of theſe infoldings is chiefly the cauſe, why oftentimes moſt cruel Vomiting uſes to come upon a Fit of the Stone; and that from ſuch a Vomiting the *Cholidock* Veſſels are very much emptied, as if provoked by taking an Emetick.

The greateſt Infolding of the Meſentery being placed in the midſt of the reſt, like the Sun, diſperſes every where round about nervous Fibres like rays, *Fig.* 11. ⊙. and caſts them not only on every one of thoſe infoldings, as if ſo many Planets with a peculiar Aſpect, or *Actinoboliſm* or Irradiation, but alſo it diſtributes them into many Inteſtines, ſanguiferous Veſſels, and other parts lying round about: without doubt upon theſe nervous Filaments, which are carried from this infolding to the Inteſtines, as Lines from the Centre to the Circumference, every action of the Inteſtines, and eſpecially the Periſtaltick motion of the Vermiculation, depends; namely for that theſe Fibres do move ſucceſſively, and ſtill move further every begun action, as it were with a ſpiral or Screw-like progreſs.

That from this Infolding many Fibres and ſhoots going forth, are inſerted into the Trunk of the *Aorta* nigh its deſcending, and that theſe reaching towards the Inteſtines, accompany the Blood-carrying Veſſels, and in ſeveral places climb over them; from hence it may be inferred, That nerves alſo in the Abdomen are like Bridles and Reins caſt on the ſanguiferous Veſſels, which either by ſtraining or pulling them together, may ſometimes retard, ſometimes incite the courſe of the blood according to the needs of the lower *Viſcera*.

From the greateſt Infolding of the *Meſentery* ſome noted Fibres and ſhoots are ſent out into the *Glandula's* of the Womb or the Womens Teſticles, *Fig.* 11. *τ. τ.* Into which alſo other ſhoots from the Trunk of the intercoſtal Nerve, *ibid. v. v.* and others going out of the nerve which comes between this infolding and the loweſt of the Abdomen, do come together, *ibid.* ⸸. ⸸. So that a proviſion of Spirits is carried into thoſe parts from a threefold Store-houſe; which indeed is much larger than is done in the other Sex, when we find ſcarce any nerve to belong to mens Teſticles. Indeed the Womb, beſides that it is a very ſenſible part, ought alſo to be moved diverſly, and in bringing forth a child very ſtrongly: wherefore there are granted to this both more ſtrong implanted Fibres, and alſo Nerves of a various kind and original.

Moſt of the Infoldings of the Abdomen, but eſpecially the loweſt, and that related to it the greateſt of the Meſentery, are oftentimes affected in the Paſſions commonly called Hyſterical, as ſhall be preſently declared. Therefore if at any time ſuch diſtempers proceed from the Womb, the cauſe is manifeſt wherefore the aforeſaid infoldings are drawn into conſent. But we have elſewhere ſhewn, That thoſe Paſſions are merely convulſive, and not ſeldom excited without any fault in the Womb. Further, that Symptom very frequent in thoſe kind of Fits, to wit, in which as it were a Globe is perceived to be carried from the bottom of the Belly, and about the Navel to leap out impetuouſly, which therefore is thought to be an aſcent of the Womb; I ſay, that it is nothing elſe than moſt cruel Convulſions of theſe infoldings. Indeed oftentimes in Women, and ſometimes alſo in Men, I have known when the convulſive Affection hath invaded, that a bulk in the *Hypogaſtrium* hath been ſeen to ariſe, then about the midſt of the *Abdomen* ſo great a ſwelling to follow, that it could not be hindred or preſt down, though ſtrongly attempted by the hands of a ſtrong man. Without doubt, the cauſe of this admirable diſtemper is, that within the nerves of the intercoſtal pair the inflowing animal Spirits, as often as they beign diſorders or convulſive motions, firſt (as it is wont to be) begin to grow hot or to be exploded about the extremities of the nerve, to wit, in the loweſt infolding of the *Abdomen*; which affection of theirs, when creeping upwards it is carried to the greateſt infolding of the Meſentery, ſo that the Spirits inhabiting it are taken with the like inordination, it is no wonder, if that ſwelling up of the middle of the *Abdomen*, and as it were an exploſion of a certain nitroſulphureous matter, ſhould be ſtirred up. For truly it is not probable,

probable, that that Symptom ſhould be excited from the Womb aſcending and being removed from its place, becauſe, beſides this part being fixed in its place and firmly eſtabliſhed with Ligaments, the bulk of it alſo in Virgins is ſo ſmall, ſcarce exceeding the bigneſs of a Walnut, that although it ſhould be carried up into the Belly, it could not produce ſuch a ſwelling. Nor is it more likely, that this ſort of diſtemper is ſtirred up from the Muſcles of the *Abdomen* taken with a Convulſion: for they, however convulſive, draw together themſelves and ſubjected parts upwards or downwards, or of one ſide, but they are not able by any means to bear themſelves aloft, and to lift up on high, with a force, the region of the Navel. But, as we ſuppoſe, the animal Spirits in the greateſt infolding of the Meſentery growing fierce, and becoming apt to be exploded, (as ſuch indeed they are whenever they enter into convulſive motions) they being there gathered round thickly into a Globe, do mainly blow up and lift on high with their effervescency and notable rarefaction that infolding with its whole neighbourhood, and at once drive upward the *Viſcera* lying upon it with a certain vibration or ſhaking. A more full explication of this Symptom belongs to the Pathology of the brain and Nerves.

In the mean time we ſhall take notice, that another certain Diſtemper, *viz.* the *Colical* grief doth belong to the infoldings of the *Abdomen*, and eſpecially to this greateſt of the Meſentery. For it may be thought, that the moſt cruel torments that are wont to be excited in this diſeaſe do come, not from an excrementitious matter ſhut up in the cavities of the Inteſtines, nor always from a ſharp humor impacted in their Coats, but oftner from the nervous Juyce imbued with a certain acrimony, and ſtagnating within this infolding; from whence, by reaſon of a conſent of this with the infoldings both Hepatick and Splenetick, a frequent and cruel Vomiting comes upon theſe pains. But theſe *Pathologick* Speculations being referred to their places, we will follow what we firſt of all inſtituted, the further paſſage of the intercoſtal Nerve, by which we are led to the two leſſer and loweſt Infoldings of the *Abdomen*.

Below the Meſenterick Nerves, out of which the ſuperior Infoldings are made, either deſcending intercoſtal Trunk ſends forth three or four ſingular ſhoots, which are carried into the Ureters, *Fig.* 11. *v. v.* The uſe of theſe ſeems to be, to pull together, and to jog or ſhake thoſe urinary Chanels, that the Serum ſeparated in the Reins, may be the more readily drawn out towards the Bladder. Moreover, if at any time a viſcous or muddy matter doth ſtick to the paſſages of the Ureters, or a more fixed ſtone doth obſtruct their Cavities, they, by the help of the Nerves inſerted here and there in their whole tract, being pulled together and wrinkled, may preſs down and always move forward any bulk or ſubſtance ſtaying in the paſſage.

Nigh the *Vertebræ*, out of which the Crural Nerves begin to go forward, three diſtinct branches brought to either intercoſtal Nerve, are carried from thence into the loweſt hollowneſs of the Belly, where they make the infolding which is the loweſt of the *Abdomen*, *Fig.* 11. ♑. ♌. ♌. ♌. That here ſo many nerves, to wit, ſix large ones joyning together do make but a ſmall infolding, *viz.* a leſſer than is raiſed higher in a ſingle branch of the nerve; the reaſon is, becauſe this infolding is like an Inn, where the infolding Spirits dwell no long time, but it receiving them only in their paſſage, preſently commits them to other infoldings placed here and there above, below and of one ſide, and made for divers offices; for from hence the chief paſſage, and as it were a broad way, leads to the greateſt infolding of the Meſentery; moreover, from hence nerves, diverſly going out, make three other infoldings, which reſpect the parts and ways by which the ſeveral Excretions, to wit, of the Dung, Urine, and Seed are made in the lower Belly.

The firſt Nerve therefore ſent out of this loweſt Infolding into the greateſt of the Meſentery, a little before it reaches to it, imparts two noted ſhoots to the Glandula's of the Womb; but in its aſcent it admits four other branches, as it were ſubſidiary, *viz.* two on either ſide from the intercoſtal pair, *Fig.* 11. χ. ſo that the nerve here ſeems to be the chief means of paſſage of the animal Spirits deſtinated to the greateſt infolding of the Meſentery and to the uterine Glandula's; which paſſage however is carried into the deſigned parts, not immediately; but a compaſs being made, it firſt goes forward beyond its bound, and at length with a certain going back. The reaſon of which is, that the motions of all the Inteſtines, *viz.* the Vermiculations ſhould be directed downwards towards the ſtraight Inteſtine, and alſo that the actions of the Womb ſhould tend thither; therefore 'twas fit, that the animal Spirits ſhould be ſupplied from below whither the motion inclined. For by the like means, this Meſenterick nerve and the two returning nerves, being firſt carried lower, aſcend into their Provinces; to wit, that they may pull together the reſpective parts toward that bound placed below, as it were to a Pully.

Further, for this end, to wit, that the influence of the Spirits actuating ſome Inteſtines, might be derived lower; the other infolding of the Abdomen, to wit, the leaſt, is added immediately to this. Becauſe upon the Nerves being carried from hence about an inch, there grows a ſmall infolding; out of which, one nerve being ſent out into the greateſt infolding of the *Meſentery*, ſtretches it ſelf under the top of the ſtraight Inteſtine and part of the *Colon*. *Fig.* 11. ♀. *α*. And another nerve, deſcending from this infolding, is carried under the loweſt part of the ſame ſtraight Inteſtine, *Fig.* 11. *b*. which alſo, two ſhoots carried from the infoldings placed in the *Pelvis* or Baſon, meet, *Fig.* 11. *d. d*. It will not be hard to declare the uſes of this infolding and its nerves: becauſe all thoſe nervous paſſages are emptied about the offices and motions of the ſtraight Inteſtine. The aſcending nerve directs the Vermiculations of the ſame ſtraight Inteſtine, as alſo of the the lower part of the Colon, and then (the greateſt infolding of the Meſentery mediating) of ſome other Inteſtines to be made downwards; but the deſcending nerve, in oppoſition to the other, drawing the loweſt part of the ſtraight Inteſtine upwards, takes care that the Excrements being

being carried towards the Arſe-hole, may not ſlide out ſuddenly and unexpectedly. Then foraſmuch as two nerves from the two infoldings placed within the Baſon or Tunnel, (which infoldings immediately admitting a noted Vertebral branch, are partakers of the ſpontaneous Function) meet with this deſcending nerve, and are ingraffed into it; it comes to paſs from all of them together, that the Excrements being detained at the doors, when it ſhall be convenient, the Appetite commanding are caſt out. Nature, that it might ſhun filthineſs, is ſo careful, that for the carrying out of the Excrements it conſtitutes nervous Veſſels, with as noted a proviſion, as for the performing any where of the moſt ſplendid offices.

From the loweſt Infolding of the *Abdomen*, two nerves being ſent into the Tunnel, receive there on both ſides a noted Vertebral Nerve; and ſo conſtitute two infoldings, to wit, one in either ſide, *Fig.* 11. *CC.KK.* Theſe infoldings near the doors, placed before the chief excretory paſſages, ſerve for the opening and ſhutting them: a Vertebral branch comes to either as a ſupply; by which it comes to paſs, that beſides the increaſing the forces of the Spirits, their acts flowing from theſe infoldings, become in ſome meaſure ſpontaneous. By what means and for what end, the nerve aſcending from either infolding, is beſtowed on the ſtraight Inteſtine, was ſhewn but now. Moreover, two deſcending on both ſides, are carried into the neck or porch of the Womb, *Fig.* 11. *e. g.* Without doubt, whatever of ſenſe or motion is made about the Venereal acts, is owed to the influence of the Spirits through theſe Nerves. In Men the delightful proviſion of the Genital humor, and in Women the no leſs pleaſant reception of the ſame depends on the action of thoſe nerves. Laſtly, from the ſame infolding another nerve deſcending and broken into certain ſhoots, is diſtributed on both ſides into the Bladder and its Sphincter, *Fig.* 11. *f.* Certainly by theſe nerves the buſineſs of making water is performed, and when at any time the ſame is painful, the troubleſom ſenſe is impreſſed on them. But foraſmuch as the nerves dedicated to the ſeveral Excretions proceed on both ſides from the ſame infolding, therefore the acts of them all are in ſome meaſure alike among themſelves, ſo indeed, that if any excretory paſſage ſhould be weak or ill affected, it ſends forth its charge which it ſhould keep, whether it will or no. This is ſo well known, that there is no need to illuſtrate the matter with inſtances.

Theſe Nerves and Infoldings being ſo made, there is not much buſineſs beſides left for the intercoſtal pair. About the beginning of the *Oſ ſacrum*, both Trunks inclining mutually one to the other, communicate among themſelves by a croſs ſhoot, or two, then they end in very ſmall Fibres, which are diſtributed into the Sphincter of the *Anus*, *Fig.* 11. *q. r. s.* Here the intercoſtal pair is after the ſame manner, as we have obſerved concerning the wandring pair; to wit, either nerve being brought to the end of its courſe, before they enter upon their laſt task, incline themſelves to mutual embraces. Concerning the laſt offices of either pair, this Conformity may be alſo noted; that whenas the *Viſcera* dedicated to Chyliſication, to wit, the Ventricle and Inteſtines, are ſtill continued to the laſt by the ſame paſſage and the ſame perpetual cavity or hollowneſs; the firſt doors of this Cavity, to wit, the Orifices of the Ventricle, are kept by the loweſt branches of the wandring pair joyned among themſelves; but before the laſt door of the ſame, to wit, the *Sphincter* of the *Anus*, the extremities of the intecoſtal pair, alſo before joyned among themſelves, are placed. But to this part, as if it had never provided enough for it, beſides the nerves ſent hither from either infolding next above, and theſe extreme productions of the intercoſtal pair beſtowed on it, a branch alſo and certain fibres from the Vertebral nerve are inſerted, *Fig.* 11. *i. k.* By the acceſs of which it comes to paſs, that the ſhutting and opening of this door-keeping Muſcle becomes ſpontaneous. Truly many nerves, and thoſe of a diverſe kind, are diſtributed into the *Sphincter* of the *Anus*, to wit, becauſe the nutritious Juyce and its ſtinking recrements, like a certain Chymical matter, are digeſted within the Inteſtines, as it were within a *Matrice*; therefore Nature, which beſt underſtands Chymiſtry, is very careful about the well-ſtopping the mouths of the Veſſels.

From the ſame Nerve, *viz.* the laſt Vertebral, out of which a branch diſperſes fibres into the *Sphincter* of the *Anus*, two other Nerves proceed, which are carried into the Yard, *Fig.* 11. *l. m.* The greater of theſe, which is very large and long, is diſtributed into the nervous Body of it; the other leſſer, into its Muſcles. This member, becauſe it receives nerves only from the ſpinal Marrow, according to our Hypotheſis, ought to ſwell up and to be moved only at the ſpontaneous pleaſure of the will: but that oftentimes, by reaſon of the ſwelling up of the Genital ſeed or humor, it is erected and blown up with Spirit, whether one will or no, that is cauſed chiefly for this reaſon, Becauſe from this Vertebral pair from whence the nerves of the Yard ariſe, a nervous proceſs is ſtretched out into the Vertebral pair next above it: in which the infolding, placed in the Tunnel, imparting nerves to the *Proſtatæ*, is radicated, *Fig.* 11. *I. K.* into which infolding alſo a noted nerve from the intercoſtal pair is implanted. When therefore a communication is had between the *Proſtatæ*, which depend much on the intercoſt Nerves and the Yard, (by reaſon of the roots of either being joyned together by the nervous proceſs) it comes to paſs, that the action of this follows the affection of thoſe parts; but thoſe parts, *viz.* the *Proſtatæ*, are apt to be moved, not only by the turgeſcency of the Seed, but alſo by the paſſage of the intercoſtal Nerve are wont to be irritated with too unſeaſonable an action, according to the impreſſions made by the Senſes or the Brian; into the conſent of which preſently the Yard is excited.

Concerning the Nerves which belong to the Teſticles, here is not much to be ſpoken; for we have often ſought in vain for a great company of nervous paſſages in them: I have very diligently ſearched ſometimes in Man, alſo in a Fox, Dog, Calf, and likewiſe in a Boar and Monkey, but could never find belonging to them but one nerve carried from the Vertebral pair, which alſo for the moſt part is beſtowed on the

the Cremaſteral Muſcle, *Fig.*11.*M.* ſo that, although an excellent humor is prepared within thoſe parts, yet it doth not eaſily appear, that its matter is derived thither through the nerves; for we think the Genital humor is no more diſpenſed by the nerves than the nutritious. For truly it ſeems, that the Arteries inſtil a ſpirituous liquor into the Teſticles after the ſame manner as in the Brain; wherefore in their neighbourhood theſe ſanguiferous Veſſels being very much divaricated or ſpread abroad, are turned about into little ſerpentine chanels, whereby they ſubtilize the humor deſtinated to the Teſticles, and inſinuate it, having put off all thickneſs and Feculency, and being truly ſublimated, into their ſubſtance; becauſe there, as within the Cortex of the Brain, the ſpirituous liquor being imbued with a volatile Salt implanted in the part, paſſes into the moſt noble *Clyſſus*, *viz.* the Genital humor. But here is not a place to diſcourſe more largely of the nature and origine of the Seed: yet becauſe it is commonly objected, That the Seed is made of the nervous Juyce and plenty of Spirits fetched from the Brain, and therefore a large expence of it doth induce quickly on the Brain and Nerves a great debility and enervation; I ſay, this comes to paſs, becauſe after great profuſions of the Seed, for the reſtauration of the ſame humor, (of which Nature is more ſolicitous than for the benefit of the individual) preſently greater Tributes of the ſpirituous Liquor are required from the blood to be laid up into the Teſticles: wherefore the Brain is made languid, being defrauded of its due ſtock and afflux of the ſame ſpirituous liquor; and the Spirits influencing it and the nervous *Syſtem*, becauſe they are deficient in the Fountain it ſelf, are very much depauperated and become flagging. Beſides we may add, That the animal Spirits alſo which actuate the *Proſtatæ* coming from the ſpinal Marrow, are conſumed about the Venereal acts very much; ſo that the Loyns are alſo enervated for this reaſon.

CHAP. XXVIII.

Of the Spinal Nerve an Acceſſory of the wandring Pair; alſo of the Nerve of the Diaphragma.

After we have unfolded the Nerves of the wandring and intercoſtal pair, which being Executers of the involuntary Function, are ſtretched out to the *Præcordia* and all the *Viſcera* of the middle and lower Belly, and alſo to ſome other parts: Next to theſe follow ſome other Nerves communicating with the aforeſaid in the beginning, or in the exerciſe of the ſame office, *viz.* the ſpinal Nerve and the Nerve of the Diaphragma; of which we will ſpeak in order.

We have already ſhewn, that the Nerve of the wandring pair in the beginning is made up of numerous Fibres: to which is joyned another noted Nerve ariſing from afar, and being ingraffed with them, goes forth together with them out of the Skull. Concerning this Nerve, becauſe the beginning and diſtribution of it being very irregular, have not as yet been noted by other Anatomiſts, it may ſeem worth our labour to make a little more diligent inquiry. Therefore if we would ſearch into the beginning of this nerve, that is found beginning with a ſharp point in the ſide of the ſpinal Marrow nigh the ſixth or ſeventh *Vertebræ* of the Neck, *Fig.*12.*C.C.* But being increaſed in its aſcent, is no where inſerted into the medullar Trunk, but in its whole tract on both ſides lean on its ſide, to which it is knit by certain admitted Fibres towards the ſuperficies. This ariſing up from the Neck after this manner, and being carried within the Skull, is joyned to the Fibres of the wandring pair, and is ingraffed with them ſeeming to grow together into one Trunk, and goes out with them at the ſame hole from the Skull; which being paſſed through, the ſpinal Nerve preſently departing from the Trunk of the wandring pair, is at length reflected outward, *Fig.*9. ♀.♂. This ſtranger or travelling nerve after a ſhort commerce having left his companion, is carried upon the Muſcles of the Neck, to which it imparts ſome ſhoots, and is inoculated with a certain ſhoot of the tenth pair; but from thence being carried on further, it goes alone by a long paſſage, till it comes to the Scapular Muſcle, on which it is almoſt wholly beſtowed, *Fig.* 9. ♄. This nerve is found conſtantly, not only in Man and four-footed Beaſts, but alſo in Fowls and Fiſhes; and in theſe it ſeems to be deſtinated inſtead of Arms, and for the moving of their wings and fins.

Concerning the uſe of this Nerve, and the reaſon of its irregular beginning, we ſhall conjecture after this manner: Foraſmuch as that is deſtinated for the performing the motions of the Muſcles belonging to the Arms and Neck, therefore it ought to ariſe out of the ſpinal Marrow: but that it is not carried by a direct and near way into its Province, but being carried about by a long compaſs before it enters upon its task, communicates in its beginning with the nerve of the wandring pair; certainly this ſeems to be done, to the end that this Spinal nerve, being carried into the parts of the wandring pair, might perform the acts of the Function only involuntary. And indeed it may be obſerved, That beſides the ſpontaneous motions wherewith the Neck and Arms are wont to be imployed with the previous intention of doing this or that thing, thoſe parts alſo, before any other member, are affected with pathetick and ſudden motions,

ons, according to the force of the Paſſions, the animal not being conſcious of it. For almoſt all living Creatures do not only turn about their necks at any noiſe to behold whatever might cauſe fear; but they being any ways affrighted, in the twinkling of an eye fly away, their feet, wings, fins, or other part anſwerable to them, being ſet into a rapid motion. The Neck and the Arms are pliable or obſervant, not only to fear, but in like manner to the other Paſſions. For brute Animals, as well as Man, being puffed up with pride or anger, (as we have elſewhere intimated) have their Necks ſwollen, and their Creſts lift up: But as to Man, his hands and Arms are ſo obſequious to the Paſſions, and almoſt to all the conceptions of the Brain, that they are continually agitated in the doing of any other thing with various geſtures, whereof we are ignorant or not willing them: we ſcarcely think or ſpeak any thing but at the ſame time the hands are flung out here and there; and whilſt the Tongue heſitates or ſticks, or the words as it were ſtick between the Jaws, the right hand is exerciſed, as if by its geſture it were endeavouring to draw out more ſwiftly the ſenſe of the mind. Truly that theſe parts, to wit, the Hands and Arms, do ſo nearly conſpire with the Affections of the Brain and Heart in their motions in ſome meaſure in all living Creatures, but more eminently in Man, the cauſe ſeems to be this nerv's coming from the ſpinal Marrow to the beginning of the wandring pair, and communicating with its nerves, and receiving from them as it were the note or private mark of the involuntary Function.

So much for the ſpinal Nerve, which alſo like a ſhrub, growing from other ſhrubs, hath no peculiar origine, but having received various fibres, is radicated for the greateſt part in the ſpinal Marrow, and (as hath been ſhewn) partly in the nerve of the wandring pair. Concerning the nerve of the Diaphragma, of which we ſhall ſpeak next) many things occur no leſs worthy remarking. As to its beginning, it may be obſerved, That it ariſes from the brachial nerves with a double or triple root; to wit, two or three ſhoots going out of the aforeſaid nerves, grow together into the ſame Trunk, which is the nerve of the *Diaphragma*. In man its firſt ſhoot, which is alſo the greateſt, is produced out of the ſecond Vertebral nerve; and when the firſt brachial nerve ariſes from the ſame handful of Vertebral nerves going out at this place, the aforeſaid ſhoot is rooted in its origine: wherefore, when in Brutes the firſt brachial nerve ariſes from the fourth or fifth Vertebral, the nerve of the *Diaphragma* alſo begins its riſe far lower: two other ſhoots ariſe out of the ſame ſtocks of the brachial nerves which follow next, *Fig.* 9. ϒ. φ. But the Trunk which is made out of theſe ſhoots goes forward ſingle through the paſſage of the Neck and the cavity of the *Thorax* without any branching forth, even to the *Diaphragma*, *Fig.* 9. χ. where being at laſt ſtretched out into three or four ſhoots, it is inſerted on either ſide to the fleſhy or muſculous part of it: ſo that, becauſe the *Diaphragma* is a Muſcle, and performs both its motions, to wit, *Syſtole* and *Diaſtole* by its own Fibres, the office of either nerve is only to carry bands or forces of animal Spirits requiſite for the indiſcontinued action of that part, and alſo to convey thither the Inſtincts of the Motions variouſly to be performed.

As to the firſt uſe of this Nerve, *viz.* for the paſſage of the animal Spirits, the buſineſs is performed in this Muſcle, as it is in the Heart. The Spirits flowing into the *Diaphragma* by the nerves, receive ſubſidiary Forces, to wit, a ſulphureous Copula from the blood, upon whoſe exploſion being ſtill iterated by turns, and the receiving of new, the action of this perpetual moveable depends. Concerning the Inſtincts of the Motions tranſmitted by the paſſage of this double nerve, we may obſerve, That they are, eſpecially in man, of a double kind: *viz.* either the action of the *Diaphragma* merely natural for the performing of Reſpiration, is continually reciprocated according to the uſes of the Heart and Lungs, and altered many ways in their tenour according their needs; or ſecondly, a certain irregular and unuſual motion of the *Diaphragma* is wont to be excited at the beck of the Appetite, or from the inſtigations of other parts; for the which, whilſt the reſt of the Organs of Reſpiration are compelled to conſpire, the act it ſelf of Reſpiration becomes after a various manner interrupted or unequal.

1. As to the firſt of theſe, *viz.* the unforced motion of this Muſcle, it may be obſerved, That the *Diaphragma*, with the Muſcles of the *Thorax* and the parts of either, conſpire in their motion with the action of the Lungs and Heart: and that between all theſe ſuch a joynt action may be ſuſtained, it is obſerved, That three or four branches are ſent out from the Vertebral nerves, in the branches of which the nerve of the *Diaphragma* is rooted, into the intercoſtal infolding, *Fig.* 9. Θ. and whereas from this infolding the nerves are carried into the Muſcles of the *Thorax*, by this means a communication and conſent of action is effected between theſe and the *Diaphragma*. Therefore the *Diaphragma* drawing with it ſelf the Muſcles of the *Thorax*, by reaſon of other nerves, conſpires with the *Præcordia*. Theſe in man going from the intercoſtal nerve, are already deſcribed; and in Brutes from the lower infolding of the wandring pair a nerve is ſent down into the infolding of the *Thorax*, to which beſides ſo many ſhoots and certain fibres reaching forth into the nerve of the *Diaphragma*, are inſtead of ſuch a commerce.

2. The Animal and irregular motions of the *Diaphragma* proceed from various cauſes and from the divers inſtigation of other parts, which alſo in man become much more ſignal than in brute Animals; becauſe in him the communication is notable by the nerves reaching out from the Cervical infolding of the intercoſtal pair into the nerve of the *Diaphragma*; which kind of infolding and nerves are wanting in Brutes.

As

As to the Species themſelves of irregular motions into which the motion of the *Diaphragma* is wont to be perverted, it may be obſerved, That we are able at our pleaſure to ſtop breathing or reſpiration for ſome ſpace, and preſently to take it or draw it out. In laughing, weeping, and ſinging ſometimes the *Syſtole*, ſometimes the *Diaſtole* becomes ſtronger, and is made frequenter upward or downward with a repeated ſhaking; which ſort of actions of it are made by reaſon of thoſe near commerces had between the nerve of the *Diaphragma* and other reſpective parts of the Breaſt and Face; yea indeed from hence it is effected, (as we have already ſhewn) that man is peculiarly a laughing Creature. Further, (which we have ſhewn elſewhere) from the Sympathy which happens between the parts of the Mouth and Face with the *Diaphragma* by thoſe nerves, a good reaſon of ſneezing may be given, and that Problem of *Ariſtotles* eaſily ſolved, to wit, why men alone, or chiefly before other Creatures, ſneeze, For the act of ſneezing ſeems to be made for this end, that man may not only clear his Noſe, but that all Torpor or heavineſs may be ſhook off for him from the neighbouring Organs of the Senſes, yea and from all the fore-part of the Brain: which thing eaſily ſucceeds, if the Membranes and nervous paſſages beſmearing the Noſtrils and the Sieve-like Bone, like the holes of a Sponge, being ſtrongly wrung forth or ſqueezed together, be forced to ſhed forth their moiſtures; for theſe parts ſo emptied, preſently like a preſſed Sponge, receive other humors, to wit, thoſe coming from the neighbouring parts. In the mean time, that the watry heap ſo laid up about the caverns of the Noſtrils, may be emptied, it ought to be carried away, or wiped out from thence by a vehement blowing of the Air or breath. Wherefore it is obſerved, That whilſt the inward parts of the Noſtrils being very ſenſible, begin to be wrinkled together from ſome ſharp thing pulling or pricking them, and by that means to draw out the watry humor preſently by reaſon of the paſſage from thence by the branches of the fifth pair into the intercoſtal Trunk, and from thence by the paſſage of the nerves which are extended from its Cervical infolding into the nerve of the *Diaphragma*, the conſent of the ſame Action or Convulſion is produced even into the croſs bound or Midriff; ſo that by the ſame Act as it were with which the Noſtrils are wrinkled, the *Diaphragma* alſo with the *Diaſtole* being ſtronger and longer drawn out, is depreſſed, that the Breaſt being dilated as much as may be, the Air may be the more copiouſly inſpired. Then as ſoon as the Spaſm or Convulſion of the Membranes, drawn together within the Noſtrils and fore-part of the Head, begins to remit, preſently the Midriff leaping back with a force, cauſes the inſpired Air to be violently exploded or drivenout, which ſtrongly wipes away and carries forth with it the humor preſſed out within the caverns of the Noſtrils.

We yet ought to inquire concerning the Nerve of the *Diaphragma*, what is the reaſon, that it always proceeds from the Brachial nerves, and why it doth not rather ariſe immediately from the ſpinal Marrow. Truly from hence it ſeems to follow, that the motion of the Arms in ſome ſort reſpects the action of the *Diaphragma*; or on the contrary, that this depends on that. Indeed between theſe two a certain reſpect or habitude happens; which eaſily appears by this Argument: The Arms or fore-Legs in all Creatures are made for labour and hard exerciſe; becauſe by the force of theſe men fight, and perform the moſt hard and laborious things, and Brutes run and aſcend the moſt ſteep places with great pains. But it is very well known, that by too much labour and over-vehement motion of body, the act of Reſpiration is very much increaſed, ſo that the breath almoſt fails, and is oftentimes in danger to be loſt. The reaſon of this is, becauſe by great exerciſe the blood is too much forced into the boſom of the Heart, which, leſt it ſhould ſuffocate it, that it might be emptied into the Lungs, very frequent and difficult Reſpiration is inſtituted. Therefore from hence may be inferred, That the exerciſes of the Body ought to be regulated according to the ſtate of the *Præcordia*; or that the motion of the Arms ſhould obſerve the action of the *Diaphragma*, *viz.* leſt they being ſtirred by a violent motion, cauſe the blood to be driven more into the boſoms of the Heart, than the *Diaphragma* inſtituting a moſt frequent Reſpiration, can draw from thence into the Lungs. That this Rule may be perpetually obſerved of all living Creatures it is ſo provided, that the nerve of the *Diaphragma*, chiefly conducing to Reſpiration, ſhould be tyed, as it were a bridle, to the Brachial nerves, which are the principal in the motion of the Body, and ſo might timely warn theſe, if unmindful of their duty, and as ſoon as breath fails, ſhould command them to deſiſt from further moving the Body. Wherefore we obſerve, when at any time labouring Cattle are urged beyond their ſtrength in labour or motion, oftentimes either ſome deadly hurt of the heart follows, or elſe ſome uncurable diſeaſe of the *Diaphragma*; for by ſuch immoderate labour, either the Beaſt languiſhing quickly dyes, when it is commonly ſaid, that his heart is broke; or elſe the tone of the *Diaphragma* being wholly broken, Reſpiration ever after becomes painful and difficult: which is wont to happen ordinarily to Horſes, who are driven into too rapid a courſe with a full Belly.

CHAP. XXIX.

Of the Reaſon of the difference that happens between the Nerves of the wandring and Intercoſtal Pair in Man and brute Beaſts; alſo of the other Pairs of the Nerves ariſing both within the Skull, and from the Spinal Marrow: alſo ſomething of the Blood-carrying Veſſels which belong to the Spinal Marrow.

THus far we have deſcribed all the Nerves ſtretching out to the *Præcordia* and *Viſcera*, alſo to moſt of the other parts, which are the Organs of the involuntary Function, according to the manner by which they are wrought in man; and we have ſhewn their Offices and Uſes, and the Reaſons of the moſt noted appearances in all. Before we proceed to the other Conjugations of the Nerves, it behoves us to ſhew with what difference the aforeſaid Nerves are found in brute Beaſts, and for what end ſuch a difference is ordained.

It was already intimated, That the Trunk of the wandring pair in four-footed Beaſts doth ſend forth to the Heart and its Appendix more nervous Veſſels than in Man. The reaſon of which is obvious; becauſe the Cardiack nerves in Brutes proceed almoſt only from this pair, and ſcarce at all from the intercoſtal; wherefore when they are only of one orgination, therefore more are required, all which notwithſtanding are much fewer than the ſame are in Man from a double ſtock, *viz.* being carried from both the Nerves: foraſmuch as Beaſts want prudence, and are not much obnoxious to various and divers Paſſions, therefore there was no need that the Spirits ſhould be derived from the Head into the *Præcordia* by a double paſſage, *viz.* that one ſhould be required for the exerciſe of the vital Function, and the other for the reciprocating impreſſions of the Affections; but that it may ſuffice, that all thoſe deſtinated to every one of their offices, may be carried ſtill in the ſame path.

In moſt Brutes the intercoſtal Nerve goes alone from the Ganglioform infolding of it almoſt without any branching to its infolding of the *Thorax*: in which paſſage however it is not always after the ſame manner in all; for in ſome it is carried ſingle and apart from the Trunk of the wandring pair, nor doth it communicate with it in its whole journey, unleſs a little higher by a ſhoot ſent down from the Ganglioform infolding: but in many the intercoſtal Nerve paſſes preſently from its Ganglioform infolding into the neighbouring infolding of the wandring pair, *Fig.* 10. *C.* where, when both nerves ſeem to cloſe together, from thence both being involved under the ſame common incloſure, as it were one Trunk, they are carried together till it comes over againſt the firſt Rib, and there an infolding being made, the intercoſtal nerve, departing from the wandring pair, is carried into the infolding of the *Thorax*; and the other nerve alſo is ſtretched between this and that infolding: which nerves, when one is carried under the other above the Artery of the Chanel-bone, making as it were an handle, ſtraiten its Trunk, *Fig* 10. *g.*

Although the intercoſtal Nerve is carried from the Throat to the top of the *Thorax* under the ſame ſheath with the Trunk of the wandring pair, yet it is not united to it; but they remain diſtinct ſtill both of them in the whole tract, and the Membrane being diſſected, they eaſily ſeparate one from the other, unleſs they be knit together by ſome fibrils ſent from one another in ſome places: but foraſmuch as by this means the intercoſtal nerve being joyned to the Trunk of the wandring pair, goes under its cover, it ſeems to be ſo made only for its ſafety and better paſſage: wherefore in ſome perhaps where the intercoſtal Trunk is greater, or the courſe of its paſſage ſhorter, where ſuch a ſafeguard is not needful, it deſcends alone. We have ſeen this Nerve covered with the ſafeguard of the wandring pair of one ſide, and in the other to have gone out by it ſelf alone.

Whether the intercoſtal Nerve departs from the lower Infolding of the wandring pair or not, however a branch is ſtretched out between this infolding and that of the *Thorax* in many, perhaps in all brute Beaſts; which in its paſſage binds about the Vertebral Artery, whereby the *Sympraxis* or joynt Action between the *Præcordia* and the exterior Organs of Reſpiration is ſuſtained: yea from this lower infolding of the wandring pair ſometimes we have obſerved a ſhoot and fibres to be carried to the beginning of the Brachial branch, in which the nerve of the *Diaphragma* is rooted; alſo ſometimes, though rarely, we may have ſeen ſome ſhoots ſent from the infolding of the *Thorax* towards the Heart and its Appendix. In a Monkey above this infolding of the *Thorax*, as we have intimated before, were ſome ſhoots and ſmall branches reaching from the intercoſtal nerve towards the *Præcordia*.

We

We may take notice concerning thoſe Nerves below the *Præcordia*, diſtributed every where into the Ventricle and the lower *Viſcera*, that there is ſcarce any difference of them in Man and Beaſts. The nerve of the *Diaphragma* is placed lower in four-footed beaſts: the reaſon of which is, becauſe the Brachial nerves, out of which that ought to proceed, ariſe lower; to wit, becauſe Brutes have longer necks, as if deſtinated to the yoke. Theſe things being thus premiſed concerning the difference of the Nerves in either Species, it remains that we paſs on to the unfolding the remaining pairs of them.

Therefore of thoſe ariſing within the Skull, the ninth pair is made up of many Fibres alſo in its beginning, (as was ſhewed before) out of which being gathered together, one Trunk being made is carried towards the Tongue, through whoſe whole ſubſtance, to wit, from the bottom to the top, having paſſed, it diſperſes in its whole paſſage ſmall ſhoots on either ſide, *Fig.* 9. ☉. So that nothing is more obvious than that this nerve performs the motions of the Tongue requiſite for the articulation of Sounds, as the nerves of the fifth pair ſpread into this member, ſerve for the diſtinguiſhing of Taſtes; for the exerciſe of either Faculty, *viz.* both motive and ſenſitive, the texture of Tongue being notedly fibrous, hath the virtue of a double Organ; therefore by the two nerves, beſides the ſupplements of Spirits, are carried both the Inſtincts of the Motion and the ſenſible Impreſſions.

That the aforeſaid Nerves of the ninth pair may more eaſily perform the motions of the Tongue, it ſends forth downward one ſhoot before the entrance of the Tongue, which is united with a ſhoot from the tenth pair meeting it deſtinated to the *Sternothyroeidal* Muſcle; and the other little branch of the ninth Conjugation is diſtributed into the Muſcles of the Bone *Hyoides*, *Fig.* 9. ⊙.⊙. In truth theſe ſhoots being ſent down as ſo many little ropes, conduce to the moving of the Muſcles, which are fixed to the bottom of the Tongue, which Muſcles being placed as ſo many Props to the Tongue, do facilitate its motion.

The Nerve of the tenth pair, although it may ſeem to ariſe within the Skull with many little Fibres alſo, yet being ſent down from thence into the bony Cloiſters of the *Spine*, not ariſing but within the firſt and ſecond *Vertebræ*, it is carried without. Preſently after its entrance it ſends forth two nerves into the infolding of the intercoſtal nerve; for what end hath been already ſhewn: But its chief Trunk ſpreading downwards, and receiving a ſhoot produced from the ninth pair, is beſtowed on the *Sternothyroeidal* Muſcle. Moreover, this nerve reflects branches outwards, which are diſtributed into the Muſcles of the Neck reaching out towards the hinder part of the Head; ſo this pair, as if it were only of the number or rank of the Vertebral nerves, imparts ſome branches to the intercoſtal nerve, and all the other ſhoots and branches of it ſerve for the performing of the motions of the Muſcles of the Neck, *Fig.* 9. *H.* ✳.□.△.

So much for the Nerves ariſing within the Skull, which (as was ſhewn) having their being from the parts of the Brain or Cerebel, are deſtinated to the offices of the ſpontaneous or the involuntary Function, and are chiefly diſtributed into the Organs of the Senſes or the *Viſcera* of the vital and natural Faculty. There remain many other Conjugations of Nerves, the roots or beginnings of which conſiſt in the ſpinal Marrow, which is only the exterior production of the oblong Marrow. Theſe ſpinal Nerves, beſides ſome branches that they beſtow on the intercoſtal pair, are imployed almoſt wholly on the muſculous ſtock, and the office of them is to carry outwardly the forces of the Spirits and the Inſtincts of the Motions to be performed, and to convey inwardly the impreſſions of ſenſible things. Foraſmuch as the ſpinal Marrow ſeems to be derived from the Brain, and is as it were a broad and high road produced or leading from the ſame, without any paths or tracts inſerted to it from the Cerebel, therefore the animal Spirits flowing within its nerves, do almoſt wholly execute the Acts of the ſpontaneous Function.

To deſcribe all the ſeveral pairs of the ſpinal Nerves, and to rehearſe all their branchings, and to unfold the uſes and actions of them, would be a work of an immenſe labour and trouble: and as this *Neurologie* cannot be learned nor underſtood without an exact knowledge of the Muſcles, we may juſtly here forbear entring upon its particular inſtitution: but it may ſuffice concerning theſe nerves and their medullar beginning, that we adverti ſe only in general what things may occur moſt notable and chiefly worth taking notice of.

As to the Nerves therefore produced out of the ſpinal Marrow, it may be obſerved, That in both ſides of it, nigh the outward margine or brim, four or five Fibres ariſe in the ſuperior brim, and as many in the inferior: either maniple or handful paſs through with diſtinct Fibres the *Pia Mater*, or the loweſt Coat ſpinal Marrow, which is as it were the common ſheath of them all; but afterwards the Fibres paſſing through the third Membrane of either margine, (for three cloath the ſpinal Marrow) they joyn together, and having cloathed themſelves with a Coat gotten from the ſecond Membrane, they become as it were one Trunk; which Trunk going out at the ſpace between the knot of the *Vertebræ*, is again divided into many nerves deſtinated to ſeveral parts. After this manner in the whole tract of the ſpinal Marrow, the Vertebral nerves have their birth; but in thoſe places where the *Brachial* and the *Crural* nerves go out, both the thickneſs and the breadth of the ſpinal Marrow are increaſed, and alſo the handfuls or bands of the Fibres are larger. All theſe are well repreſented in *Fig.* 12.

The Brachial Nerves are not only far greater than the Vertebrals, ſo that they appear as it were large and broad nervous chords; but that they may conſpire together, and ſerve for the ſtrong motions of the Arms, or the fore-Legs of Beaſts, it is obſerved, That very many of them are knit together by the croſs nervous Proceſſes. Theſe Proceſſes in four-footed Beaſts (the fore-Legs of whom are deſtinated for un-

wearіable pains and difficult labour) are produced croſs-ways after a curious manner, as may be diſcerned, *Fig.* 10. *l.l.* The uſe of theſe ſeems to ſuſtain not only the conſent of action in many nerves together, but alſo their mutual ſtrength; that ſome bands of Spirits might awaken or ſtir up others, and for the exerciſing ſtrongly the locomotive force, they might mutually ſupport and relieve one another. And not much unlike this, the buſineſs is about the Crural Nerves, where nervous cords ſignally large, being produced from the Junctures of the *Vertebræ*, whilſt they deſcend towards the Thigh, they which are above receive in their whole tract the nervous Proceſſes which are ſent out ſtill from thoſe below, *Fig.* 11. *p.p.p.*

We may yet take notice farther concerning the ſpinal Marrow, that as it ſends out Nerves by bands, and as it were by troops, in an orderly ſeries and military order; ſo its ſanguiferous Veſſels are diſpoſed with no leſs ſignal artifice. For thoſe which are carried in the ſuperficies of the ſpinal Marrow, and the Arteries, Veins, and other Sanguiducts, which are nigh its compaſs, do contain ſome things more rare and highly worth the noting.

In the firſt place we may obſerve, That the blood-carrying Veſſels do cloath the whole ſubſtance or frame of the ſpinal Marrow, as well as the oblong Marrow with a thick ſeries of ſhoots; which may be made more manifeſt to any one, if firſt of all Ink were injected into the Vertebral Artery; for from ſuch an injection often repeated, it will eaſily appear, that the infoldings of the Veſſels do cover as it were in the ſhape of a Net, the upper tract of the Marrow. But by what means theſe Veſſels proceed on both ſides from the Trunk of the Vertebral Artery, and alſo the blood-carrying Veins, which are deſtinated to the whole ſpinal Marrow, and the inferior portion of its arterious paſſages, doth not ſo plainly appear; becauſe the bony Cloiſters of the *Vertebræ* are not broken through without much labour, eſpecially in grown up living Creatures; and in that work the beginnings and branchings out of very many Veſſels are wont to be blotted out: But that we might more accurately ſearch into theſe hid things, we made the diſſections of ſeveral *Embryons*, in which we were able to diſſect more narrowly into all the receſſes of the Bones: further, that all the tracts and branchings out of them might be the better perceived in all the Veſſels, we did caſt in divers coloured Liquors. And we had our deſired wiſh: for preſently we found with much admiration, that thoſe kind of Veſſels, *viz.* Arteries, Boſoms, and Veins, which reſpect the Head, belong alſo to the ſpinal Marrow with no leſs a noted diſpoſition of proviſion.

When we did diſſect the Heads apart from the Spine, we did think, according to the Opinion of the Vulgar, that the Vertebral Arteries did belong only to the Head: and when there did appear in the cut off Trunk of the oblong Marrow three arterious branches (as they are deſcribed above in the firſt and ſecond Table) therefore in the Explication of either Figure we have affirmed the Vertebral Artery to be carried with a triple branch into the hinder part of the Head. But the Vertebral Artery pays to the ſuperior part of the Spine as great Tributes of Blood as to the Head it ſelf; and that middle arterious branch, which is marked in the firſt Figure with the Letter T, in the ſecond with S, doth not aſcend into the Head, but deſcends from that concourſe of Vertebral Arteries towards the Spine, and conveys downwards from the common flowing together of the blood there made by many Arteries, the *Latex* for the watring top of the ſpinal Marrow. Wherefore in this place it ſeems convenient, that we do not only correct that errour of ours, but that we deliver an exact deſcription of all Veſſels which are deſtinated to the Spine, *viz.* which contain many wonderful things. As therefore theſe Veſſels are of a threefold kind, *viz.* Arteries, Boſoms, and Veins, we will expoſe each of them particularly; and firſt concerning the Arteries we ſay.

The Arteries which carry the Blood towards the Spine, are diſpoſed after one manner above the Heart, and after another below it. As to the firſt, whereas the Trunk of the *Aorta* being there cleft preſently into many branches, departs from the Region of the Spine, therefore the Vertebral Artery is produced on both ſides from its axillary branches, which aſcending ſtraight into the hinder part of the Head, ſends forth a branch into the meeting together of every *Vertebræ*: But below the Heart, foraſmuch as the *Aorta*, in its whole deſcent, lyeth on the Spine, two Arteries are received into the Spine from its bottom nigh its *Internodia* or ſpaces between the knots of the *Vertebræ*; ſo that if the Trunk of the *Aorta* be cut open long-ways, there will appear a ſeries of double holes through its whole tract, after a moſt curious manner, as in the head of a Lamprey.

The arterious Branches which are carried both above and below the Heart towards the Spine, becoming preſently forked, beſtow one ſhoot on the neighbouring Muſcles, and another they inſert into the Junctures of the *Vertebræ*; which being carried within the bony den, is cleft preſently into three branches, two of which are beſtowed on the medullar Trunk, and the other on the Membrane compaſſing about the bony den before, *Tab.* 13. *Fig.* 3. *a.b.c.d.e.*

As to the ſhoots deſtinated to the medullar Trunk, they preſently tending two ways, and meeting with either maniple or band of nervous Fibres, aſcend towards their beginnings; and ſo one little Artery having got to the ſuperficies of the hinder Marrow, diſtributes into it hairy Veſſels: but the other arterious ſhoot, which is the greater and chiefeſt, as ſoon as it attains the margin of the former Marrow, is carried from thence by an oblique paſſage into the middle fiſſure or cleft of it, where meeting with a ſhoot of the pair of the other ſide, it is united to the ſame, and from that joyning together the arterious Trunk, as it were a common paſſage, and made up of either Vertebral ſhoot, deſcends into that cleft by the open ſpace of one of the *Vertebræ*, and in that ſhort paſſage both diſpenſes little Arteries on either ſide,

ſide, and alſo inſerts them leaning on the *Pia Mater* more deeply betwixt the ſides of the Marrow: and ſo whereas in the whole tract of the Marrow, the chief Trunk of every Artery is carried into the middle cleft, it ſeems at firſt ſight, as if the ſame arterious Trunk were carried under the whole ſubſtance of the Marrow from the head to the tail, *Tab.* 13 *Fig.* 1. Further, as by a concourſe of ſeveral ſhoots of either ſide, the ſpinal Artery deſcends above the cleft of the Marrow; ſo where the Trunks of the Vertebral Arteries joyn together (which happens to be done ſometime in the hinder part of the Head above the oblong Marrow, and often in the Neck above the ſpinal) an arterious branch ſomewhat bigger than the reſt is ſtretched out downwards. This formerly (as we mentioned but now) we miſtook for the third aſcending branch of the Vertebral Artery. But I have often taken notice, that in Brutes, where the Vertebral Arteries have met together with an acute Angle above the medullar Trunk, they are preſently, departing one from another, ſtretched out directly to either brim of the Marrow, from whence immediately being bent back, they are carried again into a mutual meeting, ſo that between their two joynings together is made the figure *Rhomboides*, as it is in *Tab.* 13. *Fig.* 1. *C.* The reaſon of which without doubt is this; to wit, that the more rapid courſe of the blood going towards the Head might be hindred by its flood being a little ſpace divided.

The third Brancy of either Vertebral Artery being carried into the anterior Cavity of the bony Den, and being preſently made forked, tends to the right and left, and is on both ſides inoculated to the next ſhoot of the ſame ſide and by the croſs proceſs, they of either ſide are united after the ſame manner; and ſo all the Arteries of this cenſe or rank receive one another mutually, as it were links of a chain, in the whole tract of the Spine, and are continued in the ſame bending paſſage. If Ink be caſt into the Trunk of the Vertebral Artery and moſt of the hollowneſſes of the *Aorta*, all theſe Arteries dyed with the ſame, will appear a pleaſant ſpectale, like Net-work, as may be ſeen *Tab.* 13. *Fig.* 3.

The top of this arterious Infolding being carried into the Skull, inſerts two ſhoots ſent forth ſtraight into the wonderful Net, and imparts two others going out ſide-ways on both ſides to the *Dura Mater*; the lower end of the ſame reaching to the *Os Sacrum*, ends in very ſmall Veſſels which ſerve for the Membrane of the Bone.

If it ſhould be asked, For what end theſe Arteries being concatenated with ſuch frequent ingraffings are diſpoſed within the Back-bone: This ſeems to be ſo ordained for three uſes: *viz.* Firſt, Theſe Veſſels (as alſo the paſſages of the Boſoms) are divaricated after this manner with repeated compaſſing about, that a conſtant heat from the blood being ſo turned about, as it were into frequent Whirlpools, might be ſupplied about the compaſs of the ſpinal Marrow, as it were by a *Balneum Mariæ*; even ſuch a manner of office as the *Choroeidal* infolding performs within the infolding of the Brain. Secondly, Care is taken by this means, leſt the blood deſtinated for the ſpinal Marrow, might flow thither too plentifully, or might be defective in its due influx; for the blood being about to flow into the medullar ſtock plentifully, is diverted from the little branches *c.d.* into theſe Emiſſaries *e.f.* and in its defect the ſubſidiary proviſion being called out of the middle infolding through the chanel *e.* into the Veſſels *c.d.* is derived into the ſame medullar Trunk. Thirdly, The uſe of this arterious infolding ſeems to be, that the blood may be diſtributed from its paſſages into the Membranes, *viz.* which is carried every where from them through the Capillary Veſſels; the reliques of which alſo are ſupped back by the little chanels ſent out of the boſoms. Further, from this Store-houſe, if neceſſity urges, a certain proviſion is had for the wants of the Brain; wherefore from hence the ſmall Veſſels end in the wonderful Net.

So much for the Arteries diſtributed about the *Spine* or Back-bone; the Veſſels of the ſecond ſort are the Boſoms which come between the Arteries and the Veins for the uſe of the ſpinal Marrow no leſs than of the Head it ſelf, and are here ordained with a more curious implication. But the reaſon why boſoms are required to theſe more noble parts, and ſcarce to any in the whole Body beſides, is this, to wit, that about theſe bodies all manner of extravaſation, or any ſtagnation of the blood, might be hindered: but ſometimes the Veins are not ſufficiently emptied, that they may preſently receive from the Arteries the depoſited blood, and ſo may prohibit any flowing out of it; wherefore the boſoms, as more fit receivers, are deſtinated to that office, for that their receptacles are larger and ſoon emptied; and for that reaſon they may more conveniently derive the blood from either medullar ſubſtance, leſt it ſhould overflow it in the Head or Spine.

As to the Figure of the Vertebral Boſom, its paſſages being conform to the arterious infolding, are put under it in the whole tract of the Spine: for after a like manner, in either boſom, which is extended within the cavity of the bony Den, from the hinder pair of the Head to the *Os Sacrum*, there is one receiving Veſſel, by whoſe twofold chanels preſently the blood is brought back from either ſuperficies of the Marrow into the boſom, and another carrying back, by whoſe paſſage the ſame is exported into the Veins. Moreover, in many Animals (though not in all) the boſoms on either ſide ſeem to be knit together upon the knots between the *Vertebræ* by the croſs proceſſes, and ſo communicate between themſelves: either boſom in its top is contiuued into the lateral boſoms of the Head; further, from it on both ſides a paſſage lyes open into the Jugular Vein and into the Vertebral, *Tab.* 13. *Fig.* 4.

What the uſe of the aforeſaid Boſom is in general was but now intimated; to wit, that the blood depoſited from the Arteries in the ſpinal Marrow, might be preſently emptied from thence, and be retained within the more large Cavities of the Boſoms, till it may be transferred into the Veins being made more emptied: But the reaſon of the divers ſorts of implications, and the frequent ingraffings which is found

about

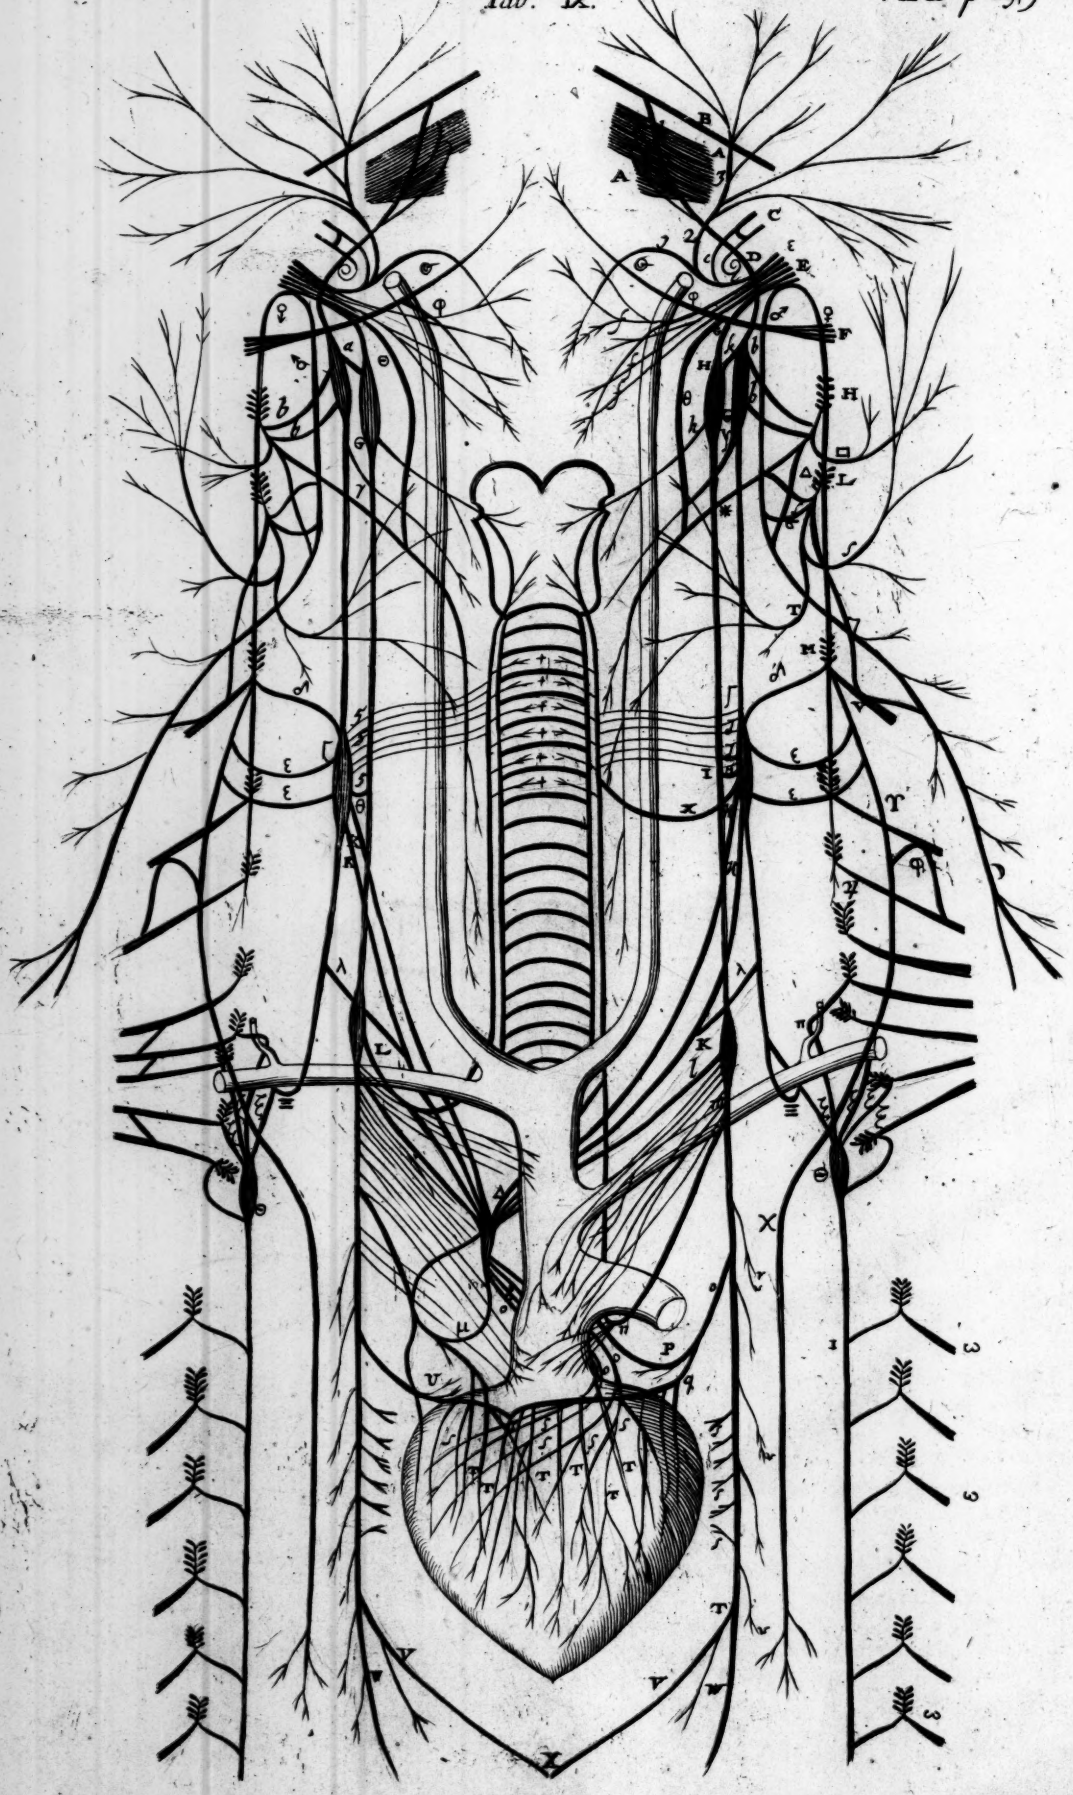
about their little chanels, ſeems to be, that the blood, if by chance it being plentifully heaped up within ſome part of the boſom, ſhould there ſtagnate, or be apt to regurgitate into the Marrow, it might be drawn out by thoſe frequent Emiſſaries here or there into the middle or oppoſite ſide: after a like manner it is with the boſoms about the Spine, as when a Country-man digs his ground frequent croſs Furrows for the draining away any ſuperfluous moiſture.

There remains another uſe of the Vertebral Boſoms, of which we made mention before, to wit, that the blood nigh the medullar Body, being brought through their variouſly intorted Meanders, (like the arterious infoldings) might yield heat requiſite for the ſwift paſſage of the animal Spirits, as it were a *Balneum Mariæ*. That the bending tracts and complications of the Boſoms may be the better ſeen, a certain tincture may be caſt into the Vertebral Veins; and preſently that invading the paſſages of the boſoms and marking them, will exhibit the appearance of a long Ladder with many little labels hanging to it.

Yea at length by thoſe little roundles we are led to the third kind of Spinal Veſſels, which are the Veins, into which all the boſoms immediately convey their burden, whereby they being continually emptied, may be ſtill able to receive freſh blood: wherefore the venous branch is ſtretched out by the ſeveral joyntings of the *Vertebræ* into the boſom, which preſently carries away the blood laid up in it, and to be reduced towards the Heart. The Veins deſigned to this office, after the example of the Arteries, are diſpoſed after one manner above the Heart, and after another below it. As to the firſt, a branch going from the Trunk of the *Vena Cava* below the Chanel-bone, or the firſt little Rib of the Breaſt, accompanies the Vertebral Artery, and aſcending by the holes of the Proceſſes between the ſeveral *Vertebræ*, inſerts a little branch to the Boſom, *Tab.* 13. *Fig.* 2. *b.b.b.* Then the top of this Vein being carried towards the hinder part of the Head, is continued into the Trunk of the Boſom, and opened by the other paſſage into the Jugular Vein. But further, as if theſe communications were not yet ſufficient for the draining away the blood, tranſverſe branches alſo are ſtretched out between both Veins, *Tab.* 13. *Fig.* 2. *i.i.i.* So manifold diverting places appear, by which it is enough and more than enough provided, leſt the blood might flow back towards the medullar Trunk upon any occaſion. Below the Heart, becauſe the Trunk of the *Vena Cava* cannot, as the *Aorta*, immediately lean upon the Spine, and carry ſhoots ſtraight to the ſame, therefore it ſends forth a Vein without a Companion, out of whoſe Trunk forked or twofold branches being ſent forth, go forwards both to the Muſcles of both ſides and to the Spine it ſelf. Below the Kidneys, ſeeing there is a ſpace granted for the *Vena Cana* to be carried nigh the Spine, the *Azygos* Vein ends, and from the Trunk of the greater Vein, as from that of the Artery, the Veſſels belonging to the Loyns immediately proceed.

Theſe things being lately obſerved concerning the blood-carrying Veſſels belonging to the Spine and the hinder part of the Head, and here inſerted in the place of an Appendix, ought to be referred to the other Doctrine of this kind, delivered above in the eighth Chapter. In the mean time, that we may return to our purpoſe, to wit, what remains of *Neurologie*, there is not much more to be met with worthy note concerning the Nerves: For they, as to the greater and chief Ramifications, are almoſt conſtantly both in Man and brute Beaſts, after the manner we have deſcribed them. Sometime it happens, although very rarely, concerning the divarications of the ſmalleſt Shoots and Fibres, that there is ſome variety: but as to the primary Veſſels, and thoſe drawn from them, the Configuration of every pair of Nerves is ſtill the ſame or alike in all. It now remains, that the Theory of the Nerves, hitherto drawn in words, and ſo only objected to the Underſtanding, may alſo be ſhewn to the Senſe, which will make it clearer. Wherefore we have taken care, that the ingraven Delineations of the wandring and intercoſtal pair of Nerves, and alſo of others which are of chief note, and of the Spinal Marrow it ſelf be plainly exhibited. The Figures of theſe, although taken from a dead Example, yet after many Diſſections and a frequent comparing them together according to their ſeveral parts, they are deſcribed as if from the life; the Lineaments of which with *Characteriſtical* Notes, that they may be the better and more diſtinctly perceived, and a large draught of every Figure, equal almoſt to the Scheme of Nerves in their animated Body, we have cauſed to be cut: further, becauſe the Contents of either ſide and of the Cavity between, cannot be at once deſcribed in their proper ſituation; therefore here it is ſuppoſed, That the *Spine*, with the oblong Marrow, or the whole medullar Stock, cut in the midſt is rolled out, and both ſides of it, with the pairs of the Nerves ariſing in the whole Tract, is turned outward.

The



The Ninth Table.

Shews the beginnings of the fifth and sixth pair of Nerves, and the Roots of the Intercostal Nerve proceeding from them; moreover, the Origines and Branchings out of the same Intercostal Nerve and the wandring Pair, and of the accessory Nerve produced out of the Spine to the wandring Pair carried to the Region of the Ventricle. Besides, here are represented the beginnings and distributions of the seventh, ninth, tenth Pair of Nerves, and of the Nerve of the Diaphragma; also the beginnings of the Vertebral Nerves in their whole Tract from the Region of the Nerves inserted in the *Præcordia* and *Viscera* are described, and their Communications with the former. All this whole following Table shews how it is found in Man different from other living Creatures.

A. *The Nerve of the fifth Pair with its two Branches* A. A. *the upper of which tending straight forwards, distributes shoots into the muscles of the Eyes and Face, into the Nose, Palate, and the upper part of the whole Mouth; moreover, it reflects two shoots* a. a. *which are the two roots of the intercostal Nerve: the other lower Branches of the fifth Pair tending downwards, is dispersed into the lower Jaw and all its parts.*

a.a. *Two shoots sent down from the upper Branch of the fifth Pair, which meeting together with the other shoot* b. *reflected from the Nerve of the sixth pair, constitute the Trunk of the Intercostal Trunk* D.

B. *The Nerve of the sixth pair tending straight forwards into the muscles of the Eyes, out of whose Trunk a shoot* b. *which is the third root of the intercostal Nerve, is reflected.*

b. *The third root of the intercostal Nerve.*

C. *The Original of the hearing Nerves or of the seventh pair with its double Proces,* viz. *soft and hard.*

c. *The softer Branch of it which is wholly distributed into the inward part of the Ear,* viz. *into the muscle lifting up the hammer, and into the shell.*

c. *The harder Branch of it, which arising whole without the Skull, and being inoculated with the shoot of the eighth pair* c. *constitutes with it a single Nerve, which presently is divided into many shoots: of which,*

1. *is bestowed on the muscles of the tongue and of the bone* Hyoides.
2. *Again into more shoots, the upper of which*
3. *Into the muscles of the Face and Mouth.*
4. *Into the muscles of the Eye-lids and Forehead.*
5. *Into the muscles of the Ear.*

D. *The trunk of the intercostal Nerve consisting of the three aforesaid Roots about to pass into the Ganglioform infolding: which infolding of the intercostal Nerve, brough without the Skull, seems to be the highest knot.*

E. *The Original of the Nerve of the wandring or eighth pair consisting of many Fibres, with which the Nerve* 9. *arising out of the Spine, joyns, and being inoculated with them, passes together through the Skull, which being passed, it departs again, and having made a communication with some neighbouring Nerves, is bestowed on the muscles of the Shoulders and Back.*

e. *A shoot of the eighth Pair meeting with the auditory Nerve.*

f.f.f. *Other shoots of the wandring Pair going into the muscles of the Neck.*

G. *The principal Branch of the same Pair being lost or drowned in the Ganglioform infolding being near.*

H. *The upper Ganglioform infolding of the wandring Pair which admits a shoot* k. *out of another near infolding of the intercostal Nerve.*

h. *A branch out of the aforesaid infolding of the wandring Pair going into the muscles of the* Larynx, *a noted shoot of which entring into the Shield-like Cartilage, meets with the returning Nerve, and is united to the same*

i. *A shoot sent from the cervical Infolding of the intercostal Nerve into the Trunk of the wandring Pair.*

K. *The lower infolding of the wandring Pair from which many Nerves proceed for the Heart and its Appendix.*

l. *A noted shoot sent to the Cardiack infolding.*

m. *Nervous Fibres distributed into the* Pericardium *and the Vessels hanging to the Heart.*

n. *The left returning Nerve which being reflected from compassing about the descending Trunk of the* Aorta *upwards towards the Scutiform Cartilage, imparts in its ascent many shoots* **** *to the rough Artery, and at length meets with a shoot* h. *sent from the Ganglioform infolding. This returning back from the knot of reflection, sends some shoots towards the Heart.*

L. *The returning Nerve in the right ſide, which being reflected much higher, binds about the axillary Artery.*

O. *A noted branch ſent down from the Trunk of the wandring pair in the left ſide towards the Heart, one ſhoot of which preſently becoming forked, compaſſes about the Trunk of the Pneumonick Vein; the other attaining the hinder region of the Heart, is diſperſed into many ſhoots which cover over its ſuperficies: a like Cardiack branch ſent out of the Trunk of the other ſide, meet with this.*

p. *The ſhoot of the aforeſaid branch going about the Pneumonick Vein.*

q. *Another branch of the ſame imparting to the Heart many ſhoots which cover over its hinder ſuperficies, turned back beyond their proper ſituation.*

r.r.r. *Small ſhoots ſent out of the Trunk of the wandring pair which are inſerted by a long tract to the* Oeſophagus.

S.S.S. *Many ſhoots cut off, the branchings of which being diſtributed into the ſubſtance of the Lungs, variouſly ſtraiten and bind about the blood-carrying Veſſels.*

T.T.T. *The Trunk of the wandring pair divided into two branches,* viz. *the exterior and the interior, either of which inclining towards the like branches on the other ſide, are united to the ſame, and after a mutual communication conſtitute the two Stomachical branches,* viz. *the upper and the lower.*

V.V. *The inward branches, which being united in* X, *conſtitute the beginning of the lower Stomachical branch.*

W.W. *The outward branches, which being united in the Figure to be added to this, make the upper Stomachial branch.*

X. *The joyning together of the inward branches.*

F. *The beginning of the Nerve of the ninth pair with many fibres, out of which being united, a Trunk being made is carried towards the tongue; but in its progreſs ſends out two ſhoots.*

Θ.Θ. *The firſt ſhoot tending downward, and united to a branch of the tenth pair, is beſtowed on the* Sterno-thyroeidal *Muſcle.*

⊙.⊙. *The ſecond ſhoot on the Muſcles of the Bone* Hyoides.

⊛. *The Trunk of this Nerve paſſing into the body of the tongue.*

G. *The upper Ganglioform infolding of the intercoſtal Nerve, which is the higheſt knot of this Nerve, being come out of the Skull.*

α. *A ſhoot out of this infolding ſent into the neighbouring infolding of the wandring pair.*

b.b. *Two nervous Proceſſes by which this infolding communicates with the Nerve of the tenth pair.*

γ. *A ſhoot ſent down into the* Sphincter *of the throat.*

Γ. *The middle or Cervical infolding, which being proper to man, is placed nigh the middle of the neck in the Trunk of the intercoſtal Nerve.*

δ. *A noted branch out of the ſecond Vertebral pair going into this infolding, whereby this communicates with the Nerve of the* Diaphragma *in its firſt root.*

ε.ε. *Two branches from the ſame infolding into the Trunk of the Nerve of the* Diaphragma.

ζ.ζ. *Many nervous fibres coming from the Cervical infolding into the returning Nerve and into the Blood-carrying Veſſels, and are alſo ſowed into the Trunks of the* Trachea *and the* Oeſophagus.

θ. *A ſhoot from the ſame into the Trunk of the wandring pair.*

χ. *Another ſignal ſhoot into the returning Nerve.*

ν.ν. *Two ſignal ſhoots ſent down towards the Heart, which another branch* λ. *follows, ariſing a little lower: theſe being carried downwards between the* Aorta *and the Pneumonick Artery, meeting with the like branches of the other ſide, conſtitute the Cardiack infolding,* Δ. *out of which the chief Nerves proceed which are beſtowed on the Heart.*

λ. *A branch proceeding a little lower from the intercoſtal Trunk, which is deſtinated with the former to the Cardiack infolding.*

Δ. *The aforeſaid Cardiack infolding.*

μ. *The handle going from the ſame, which binds about the Pneumonick Artery.*

ν. *The lower handle binding the pneumonick Vein.*

Ξ. *The intercoſtal Nerve demerſed into the cavity of the* Thorax, *where it binds the axilary Artery.*

ξ.ξ.ξ.ξ. *The four Vertebral Nerves ſent down into the infolding of the* Thorax, *the upper of which binds the Vertebral Artery.*

ο.ο.ο. *Three noted branches ſent down from the Cardiack infolding, which cover the anterior region of the Heart, as the Nerves* p. q. *going from the Trunk of the wandring pair, impart branchings to its hinder part.*

π. *The Vertebral Artery bound about by the Vertebral Nerve.*

ς.ς.ς. *Nervous ſhoots covering the anterior region of the Heart.*

τ.τ.τ *Shoots and nervous Fibres diſtributed to its hinder part.*

Θ. *The lower Infolding, called properly the Intercoſtal or Thoracical, into which, beſides the intercoſtal Nerve, four Vertebrals are inſerted: the uppermoſt of theſe in its deſcent binds about the Vertebral Artery.*

I. *The intercoſtal Nerve deſcending nigh the roots of the ſides through the cavity of the* Thorax, *where in its whole progreſs it admits a branch from between the ſeveral knots of the* Vertebræ.

H. *The Nerve of the tenth pair, consisting of many fibres in the beginning, arises between the first and second* Vertebræ, *where presently it sends forth two nervous processes* b. b. *into the upper infolding of the intercostal Nerve.*

* *A branch of it, which being united to a shoot of the ninth pair, is bestowed into the* Sternothyroeidal *Muscle immediately lying on the rough Artery.*

□. *A shoot reflected into the posterior muscles of the Neck.*

△. *A shoot into the pathetick Spinal Nerve.*

* * * *Shoots from the chief branch of the same Nerve into the* Sternothyroeidal *Muscle.*

L. *The original of the chief Vertebral Nerve, which in this, as in all other Vertebrals, consists of many Fibres, one band of which going out of the lower margine of the Spinal Marrow, and another from the upper, meeting, go together into one Trunk, which is presently divided into nerves distributed many ways.*

ϱ. *A shoot from this Nerve into the branch of the tenth pair.*

ϵ. *Another shoot into the Spinal Pathetick.*

c. *A noted shoot sent forth upwards into the muscles of the Neck and Ears.*

T. *A shoot from the crooked Nerve into the muscles of the Neck.*

7. *A Nerve from this pair into the first brachial nerve, out of which the nerve of the Diaphragma hath its highest root.*

M. *The beginning of the second Vertebral, out of which the upper Brachial branch proceeds, and in which the nerve of the Diaphragma is first rooted. This Brachial nerve in four-footed Beasts arises near the fourth or fifth* Vertebræ, *and so the root of the Diaphragma is placed lower.*

V. *The Vertebral branch destinated to the Arm.*

I. *The Nerve of the Diaphragma, a shoot of whose root δ. comes to the Cervical infolding, and a little lower two other branches from the same infolding ϵ.ϵ. are reached out into its Trunk. This communication is proper to man.*

Φ. *The other root of the Diaphragma from the second and third Brachial nerve.*

χ. *The lower Trunk of the nerve of the Diaphragma being removed out of its place, which in its proper situation, passing through the cavity of the* Thorax *without any communication, goes straight forward to the Diaphragma, where being stretched out into three shoots, it is inserted into its musculous part.*

ϯ.ϯ.ϯ.ϯ. *The other Brachial nerves, out of whose roots nerves go into the intercostal Infolding.*

ω.ω.ω.ω. *The beginnings of the Vertebral nerves, from the several roots of which a branch is carried into the intercostal nerve.*

Ψ.Ψ. *The last beginning of the Spinal accessory Nerve, going to the wandring pair, beginning with a sharp point.*

♀. *The trunk of the same Nerve ascending, which in its whole ascent, going through the side of the Spinal Marrow, passes through the midst of the beginnings of the Vertebral nerves, and receives Fibres from the stock of the Marrow.*

♂. *The trunk of the same Nerve descending, which departing from the wandring pair, is reflected outwards, and after having had communications with the nerves of the ninth and tenth pairs, it is bestowed wholly on the muscles of the Shoulder.*

☽. *The lower process of the same Nerve.*

The Tenth Table.

Shews the beginnings and Branchings out of the ſame Nerves which were deſcribed in the former Table, as ſome of them are found in brute Beaſts otherwiſe than in Man.

A. *The trunk of the intercoſtal Nerve going out of the Skull.*
B. *The upper Ganglioform infolding ſpringing out of the trunk of the intercoſtal nerve.*
C. *The intercoſtal nerve ariſing out of the aforeſaid proper infolding, and ſent down into the other neighbouring infolding of the wandring pair.*
D. *A ſhoot from the upper infolding into the Sphincter of the throat.*
E. *Both the Nerves included in the ſame ſheath, as if they were the ſame trunk, deſcend towards the* Thorax: *out of which trunk appearing in this place, a branch is ſent out into the returning Nerve.*
F. *The lower infolding in the trunk of the wandring pair, or rather conſiſting in the common ſheath of either nerve.*
f. *A ſhoot out of this infolding into the Brachial branch coming between, in which branch the nerve of the Diaphragma hath its root.*
G. *The intercoſtal Nerve departing from the ſame infoldings, and going under the axillar Artery, is inſerted into the infolding of the* Thorax.
g. *Another Branch going between the two infoldings, and going above the axillary Artery, ſo that theſe two nerves having made an handle, bind about the Artery.*
H. *A noted ſhoot out of the aforeſaid infolding of the wandring pair into the Cardiack infolding.*
i.i i.i. *From thence many nervous Fibres are ſent down into the Veſſels belonging to the Heart, and into the Pericardium.*
k.k.k.k. *The greater Brachial nerves which are produced a little lower in Brute animals, than in Man: and therefore the nerve of the Diaphragma ariſes lower.*
L.L.L. *The Brachial nerves mutually cutting one another by the croſs proceſſes, communicate among themſelves.*
M. *The Nerve of the Diaphragma conſiſting of three roots, when in Man they are only two.*
1. *The firſt root of the ſame Nerve.*
2. *Its ſecond Root.*
3. *Its third Root, which communicates mediately with the infolding of the wandring pair,* viz. *by the trunk of the Brachial branch, to which it is fixed.*
n. *A Nerve carried from the ſecond Brachial branch into the intercoſtal infolding, which binds about in its paſſage the Vertebral Artery.*
N. *Shoots and ſuckers ſent down from both knots of the returning nerve towards the Heart and its Appendix.*

The other Nerves and their Branchings out are as in the other Figure, which ſhews the pattern of them in Man.

The Eleventh Table.

Shews the lower Branchings out of the wandring and the Intercoſtal Pair, diſtributed to the Ventricle and the *Viſcera* of the Abdomen; alſo the beginning of the Vertebral Nerves, which are placed over againſt the former, and are ingraffed into ſome of them. The Figure of theſe in Man and in four-footed Beaſts is almoſt alike, ſo that this Table may be common for both.

A. *The lower Stomachical Branch which is made up out of the internal branches of each wandring pair, being united together, and covering the bottom of the Ventricle, diſperſes ſhoots on every ſide in the whole tract.*

B. *The upper Stomachical Branch which is made out of the external branches of the wandring pair, on either ſide united together, and creeps through the top of the Ventricle.*

C. *The Coalition or joyning together of the Branches.*

D. *The nervous Infolding out of the Fibres of both the Stomachical nerves, being united together nigh the Orifice, and as it were woven into a Net.*

a.a. *The ends of both the Stomachical nerves which there meet with the nerves of the Liver, and communicate with them*

E.E. *The Intercoſtal nerve deſcending on either ſide nigh the roots of the Ribs, and in its whole deſcent receiving a branch from the ſeveral Vertebral nerves ε.ε.*

F. *A branch going out of the Nerve of the left intercoſtal ſide, and ſent down towards the Meſenterick infoldings.*

G. *The ſame Meſenterick nerve becoming forked, ſends out the greater branch into the infolding, which is the Stomachical and Splenetick, and the leſſer into that belonging to the Reins.*

H. *The like Meſenterick branch going out of the intercoſtal nerve on the right ſide, and inclining towards the Meſenterick infolding.*

I. *The greater Branch of this nerve becoming in like manner twofold, the greater branch going into the Hepatick and the leſſer into the Renal infolding, or that belonging to the Kidney.*

♄. *The chief Meſenterick Infolding of the left ſide, which is alſo the Stomachical and Lienary, or belonging to the Spleen; out of which many little bundles of Nerves or numerous Conjugations are ſent ot many ways.*

♅. *The Renal Meſenterick Infolding of the left ſide, into which, beſides the Meſenterick ſhoot,*

β.β. *Two other Nerves are carried immediately out of the intercoſtal nerve.*

γ.γ.γ. *From this Infolding, planted near the Bilary Cheſt, many Nerves and Fibres are ſent into the Kidney.*

δ.δ. *Nerves and Fibres by which this infolding communicates with the greateſt infolding of the Meſentery.*

ζ. *The chief bundle of Nerves tending out of the former infolding ♄. into the Spleen, which it having reached, reflects from thence certain Fibres into the bottom of the Ventricle.*

Π. *The ſecond Conjugation of the Nerves from the aforeſaid infolding into the bottom of the Belly, whoſe Fibres communicate with the ſhoots and fibres of the lower Stomachical nerve.*

θ. *The third Conjugation of Nerves between this infolding and the neighbouring Hepatick ♂.*

ι. *The fourth Conjugation of the Nerves between this and the greateſt infolding of the Meſenterick ⊖.*

♀. *The Renal Meſenterick Infolding of the right ſide, into which (as in its fellow) beſides the Meſenterick branch.*

K.K. *two nerves are produced from the intercoſtal nerve.*

λ. *The Nerves and Fibres between this infolding and the greateſt of the Meſenterick.*

μ. *A noted Branch between this infolding and the neighbouring Hepatick.*

ν. *A noted Company of Nerves and Fibres from this infolding into the Kidney, which climb over the emulgent Veſſels, and variouſly bind them about.*

♂. *The ſuperior Meſenterick Infolding of the right ſide.*

ο. *A great Conjugation of Nerves out of this Infolding into the Liver and Gall-Cheſt, out of which alſo many ſhoots are diſtributed into the Pylorus and Pancreas. The Nerves and Fibres of this, in its aſcent towards the Liver, cover the Hepatick Artery, by making as it were a little Net, and almoſt hide its Trunk. The ſhoots of theſe meet with the tops of the Stomachical nerve α.α.*

π.π, *Shoots diſtributed about the Pylorus.*

P.p. *Other ſhoots diſperſed into the Pancreas.*

ρ. *Nerves reaching out between this Infolding and the greateſt of the Meſentery. This infolding communicates with the neighbouring Renal by μ. and with the Stomachical by θ.*

⊖. *The greateſt Meſenterick infolding out of which a mighty bundle of Nerves ..... ariſing under the great Glandula of the Meſenterick, from thence is diſperſed on every ſide about into many ſhoots and branches, and they are diſtributed into all the Inteſtines, except the ſtraight Inteſtine. I. *The greater Branch of this nerve becoming in like manner twofold, the greater branch going into the Hepatick, and the leſſer into the Renal infolding, or that belonging to the Kidney.*

♄. *The chief Meſenterick Infolding of the left ſide, which is alſo the Stomachical and Lienary, or belonging to the Spleen; out of which many little bundles of Nerves or numerous Conjugations are ſent out many ways.*

♆. *The Renal Meſenterick Infolding of the left ſide, into which, beſides the Meſenterick ſhoot,*

β.β. *Two other Nerves are carried immediately out of the intercoſtal nerve.*

γ.γ.γ. *From this Infolding, planted near the Bilary Cheſt, many Nerves and Fibres are ſent into the Kidney.*

δ.δ. *Nerves and Fibres by which this infolding communicates with the greateſt infolding of the Meſentery.*

ζ. *The chief bundle of Nerves tending out of the former infolding ♄. into the Spleen, which it having reached, reflects from thence certain Fibres into the bottom of the Ventricle.*

Π. *The ſecond Conjugation of the Nerves from the aforeſaid infolding into the bottom of the Belly, whoſe Fibres communicate with the ſhoots and fibres of the lower Stomachical nerve.*

θ. *The third Conjugation of Nerves between this infolding and the neighbouring Hepatick ♂.*

ι. *The fourth Conjugation of the Nerves between this and the greateſt infolding of the Meſenteriek ☉.*

♃. *The Renal Meſenterick Infolding of the right ſide, into which (as in its fellow) beſides the Meſenterick branch.*

K.K. *two nerves are produced from the intercoſtal nerve.*

λ. *The Nerves and Fibres between this infolding and the greateſt of the Meſenterick.*

μ. *A noted Branch between this infolding and the neighbouring Hepatick.*

ν. *A noted Company of Nerves and Fibres from this infolding into the Kidney, which climb over the emulgent Veſſels, and variouſly bind them about.*

♂. *The ſuperior Meſenterick Infolding of the right ſide.*

ο. *A great Conjugation of Nerves out of this Infolding into the Liver and Gall-Cheſt, out of which alſo many ſhoots are diſtributed into the Pylorus and Pancreas. The Nerves and Fibres of this, in its aſcent towards the Liver, cover the Hepatick Artery, by making as it were a little Net, and almoſt hide its Trunk. The ſhoots of theſe meet with the tops of the Stomachical nerve α.α.*

π.π, *Shoots diſtributed about the Pylorus.*

P.p. *Other ſhoots diſperſed into the Pancreas.*

ς. *Nerves reaching out between this Infolding and the greateſt of the Meſentery. This infolding communicates with the neighbouring Renal by μ. and with the Stomachical by θ.*

☉. *The greateſt Meſenterick infolding out of which a mighty bundle of Nerves ..... ariſing under the great Glandula of the Meſenterick, from thence is diſperſed on every ſide about into many ſhoots and branches, and they are diſtributed into all the Inteſtines, except the ſtraight Inteſtine. The Nerves and Fibres*

reaching out on every ſide, are knit to the Meſenterick Arteries and Veins in its whole compaſs, and variouſly ſtrain and bind them about.

τ.τ. Nervous ſhoots from this Infolding into the Womens teſticles, or the uterine Glandula's, which meet with the branches of the Vertebral nerves of the twentieth and one and twentieth pair ſent into the ſame parts, and are inoculated with them.

v.v. The Vertebral branches into the Womens teſticles.

☽. The loweſt Infolding of the Meſentery placed much below the former, and having for its beginning three nerves on either ſide ariſing lower from the Intercoſtals.

ϱ.ϱ.ϱ. Three Nerves on either ſide ſent down from the intercoſtal nerve into the loweſt infolding of the Meſentery.

χ.χ. A Nerve ſtretched out of that Infolding directly into the greateſt infolding of the Meſentery, which in its paſſage receives on both ſides ſome ſhoots from the intercoſtal nerve, viz. 4.4. 5. 5. 5. and it ſelf ſends two ſhoots into the Womens teſticles.

ϟ.ϟ. Two branches from the aforeſaid Nerve into the Women teſticles.

♀. Another ſmall Infolding ſtanding a little above this loweſt.

ω. A nervous Proceſs reaching out of the aforeſaid loweſt Infolding into the neighbouring very little infolding.

a. From the leaſt Infolding ♀. a noted nerve being carried into the greateſt infolding of the Meſentery, which in its whole aſcent ſtretches under the ſtraight Inteſtine and part of the Colon, and inſerts frequent ſhoots into them.

b. Another Branch ſent from the ſame Infolding downward, which ſtretches under the lower part of the ſame ſtraight Inteſtine, and imparts to it frequent ſhoots.

C.C. Two Nerves ſent downward from the loweſt infolding of the Meſentery ☽, which being ſent down into the Baſon about the loweſt cavity of the Belly, enter the two infoldings there, K.K. viz. one placed in either ſide.

K.K. A double Infolding placed within the Baſon, whoſe nerves provide for the ſeveral excretions there made, viz. of the Urine, Dung, and Seed; theſe ſend out nerves d.d. towards the loweſt Meſenterick infolding.

d.d. A nerve aſcending from the aforeſaid Infolding on either ſide, nigh the ſides of the ſtraight Inteſtine, inſerts ſhoots into it; which double infolding, another nerve deſcending (b) from the leaſt infolding, meets with.

ε.ε. Two Nerves from the ſame Infolding into the Womb.

f. A nerve from the ſame Infolding into the Bladder.

g. A nerve into the Glandules Proſtatæ.

h. A nerve out of the Root of the eight and twentieth Vertebral pair into the muſcles of the Anus.

i. The nine and twentieth Vertebral pair, from which

k. goes a Nerve into the Sphincter, and the other muſcles of the Anus.

l. A noted nerve on both ſides from that pair into the Yard.

m. Another ſhorter Branch into the muſcles of the Yard.

L.L. The intercoſtal nerve below the Reins.

m. A little nerve from the Vertebral branch into the Cremaſteral muſcle of a Mans Teſticles.

n. The one and twentieth Vertebral pair, the beginning of which being placed behind the Kidneys, lyes hid. From this Nerve very many ſhoots are ſent out on both ſides into the teſticles of the female Sex, which meet with other Meſenterick ſhoots, diſtributed to the ſame part.

o. A Nerve from the two and twentieth Vertebral pair, out of which alſo are ſome ſhoots ſent into the Womens teſticles.

p.p.p.p.p.p.p.p.p. Nerves deſtinated for the thigh, of which thoſe that ariſe higher, receive in their deſcent branches from the nerves ariſing lower.

q. The intercoſtal Nerves inclining mutually one to the other, near the beginning of the Os Sacrum, communicate by the croſs Proceſs ⊸.

r. Another croſs Proceſs within the crookedneſs of the Os Sacrum knitting together the two intercoſtal nerves.

s. Both the intercoſtal Nerves ending in moſt ſmall fibres, which Fibres are diſtributed into the very Sphincter of the Anus.

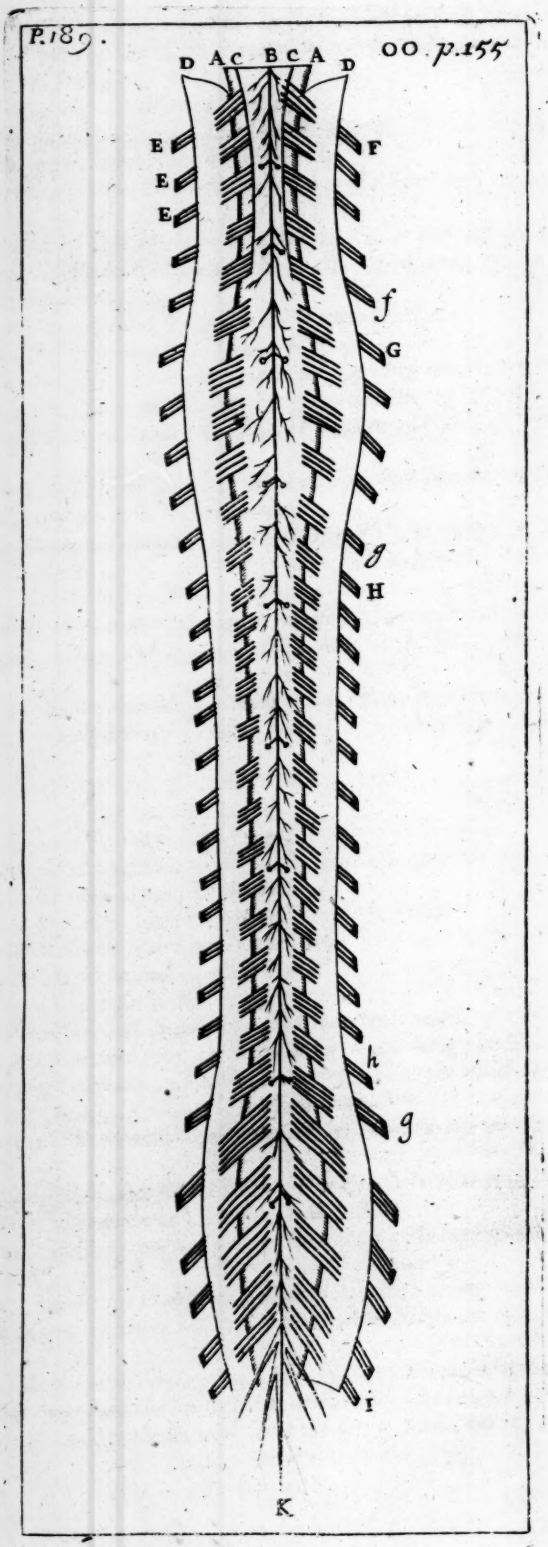
t. A Nerve from the twenty fourth Vertebral pair, which is carried into the inguinal Glandula's or of the Groyn.

v.v.v. &c. Shoots ſent down from the intercoſtal Nerve on both ſides into the body of the Ureters.

x. A Nerve which is deſtinated to the Teſticles and the Cremaſteral Muſcle, cut off where it goes out of the Abdomen.

P. 189.

OO. p. 155



The Twelfth Table.

Shews the Spinal Marrow whole taken out of its bony Den, and half taken from the Membrane cloathing it, being diſſected, that the beginnings and productions of all the Vertebral Nerves might be ſeen together.

A.A. *The top of the Spinal Marrow, where it is cut off from its cleaving to the oblong Marrow.*
B. *The Spinal Artery ſeen to deſcend through the whole Marrow, which however is made up of Arteries, brought into it from between the ſeveral joyntings of the* Vertebræ.
CC. *The Spinal Nerve coming from the fifth or ſixth* Vertebræ *of the Neck to the beginning of the wandring pair.*
D.D. *Portions of the Membrane cloathing the Marrow diſſected and rolled off.*
E.E.E. *The Spinal Nerves ſent out of the upper margine of the Marrow by bands, with which the like bundles alſo being carried from the lower margine, meet and joyn together all into one Trunk within the junctures of the* Vertebræ*: then being ſeparated again without them, they are carried into their reſpective Provinces.*
F. f. *Nerves brought forth within the region of the Neck.*
G. g. *Nerves deſtinated for the Shoulder and Arm, where both the Marrow is larger, and the bundles of the Nerves are greater.*
H.h. *Nerves going out about the Back and Loyns: where both the body of the Marrow is again ſmaller, and the little bundles of the nerves are a little ſlenderer.*
I.i. *Nerves deſtinated for the thighs, where alſo the medullar Body and the little bundles of the Nerves are again larger.*
K. *Nerves going out of the* Os Sacrum.

The Thirteenth Table.

FIGURE I.

Shews the branchings forth of the Vertebral Artery reaching out on both ſides into the ſuperiour part of the Spinal Marrow, and into the hinder Region of the oblong Marrow.

A.A. *The Region of the poſterior oblong Marrow.*
B. *The common paſſage made from both the Vertebral Arteries united together.*
C. *The Rhomboidal Figure, which in Brutes a double coalition of the Vertebral Arteries deſcribes.*
D. *The firſt joyning together of the Vertebral Arteries above the Spinal Marrow, from which place the Spinal Artery deſcends.*
E. *The Spinal Artery.*
F.F. *Two Vertebral Arteries carried from the axillary branches.*
G. *The Spinal Marrow.*
f.f.f.f. &c. *Arterious ſhoots into the muſcles of the Neck.*
g g.gg. *Shoots ſent in the Spinal Marrow which joyn together from either ſide in the Spinal Marrow nigh the ſeveral joynings of the* Vertebræ.
h.h.h.h. *Arterious ſhoots, which following the chanels of the Boſoms, make the arterious Infolding, as it is deſcribed in the third Figure.*
f.f. *Two Arteries ſent down from the* Aorta *into the Spine.*

FIGURE II.

Shews the Vertebral Veins which are Companions to the aboveſaid Arteries; alſo the upper portion of the Vertebral Boſom and the communications of either among themſelves and lateral Boſoms of the Head, and between the Jugular Veins

A. *The third Boſom of the Head cut off, where it paſſes into its lateral Boſoms.*
B.B. *The lateral Boſoms of the Head.*
C.C. *The round Den where the lateral Boſom goes on both ſides into the Jugular Vein.*
D.D. *The Jugular Vein.*
E. *The upper joynt of the Vertebral Boſoms.*
F.F. *The Vertebral Boſom on either ſide within the Skull brought through, and there paſſing into the lateral Boſom.*
G.G. *The Trunk of either Vertebral Vein brought from the* Vena Cava, *and there beginning.*
H.H. *Either Trunk of the Vertebral Boſom there cut off, which lower is continued through the whole paſſage of the Spine.*
h.h.h.h.h.h. *The joynings together on both ſides within the Commiſſures of the* Vertebræ *between the Vertebral Vein and Vertebral Boſom.*
i.i.i.i. *The Veinous paſſages, which reaching out before without the* Vertebræ, *are carried from the Vein of one ſide to its fellow of the other ſide.*
1.1. *The communication of all the Boſoms and Veins in the top of the Spine.*
k.k. *The Veinous paſſage from the concourſe of the Boſoms and Veins on both ſides into the Jugular Vein.*
l.l.l.l. &c. *The joynings together of the Boſoms of either ſide near the* Internodia *of the* Vertebræ.
m.m.m.m. &c. *The paſſages of the Veins carrying back the Blood from the Spinal Marrow into the Boſoms.*
n.n.n.n. &c. *The Chanels of the Veins carrying back the Blood from the muſcles of the Neck.*

FIGURE III.

Shews the Spinal Artery which is produced within the bony Den nigh the more inward Superficies of the Marrow, from the hinder part of the Head to the *Os Sacrum*, in the ſhape of a Net-work purl.

a.a.a.a. *Arterious ſhoots ſent towards the Spine from the Vertebral Artery aſcending between the holes of the Spinal Proceſſes.*
b.b.b.b. &c. *Arterious ſhoots ſent from the* Aorta *towards the Spine.*
c.c.c.c. &c. *An Arterious ſhoot reaching out of every of the aforeſaid ſhoots into the poſterior Marrow.*
d.d.d.d.&c. *Another ſhoot reaching out of every of the aforeſaid ſhoots into the anterior Marrow.*
e.e.e.e. &c. *Every the aforeſaid Arterious ſhoots, as ſoon as carried into the bony Den becoming forked, ſend forth a little branch into either part, which on both ſides communicates with the next branch of the ſame ſide, and by the croſs Proceſs with the fellow-branch of the other ſide.*
f.f.f.f. *The joynings together of the Arteries of either ſide by the croſs ſhoot.*
g.g. *The Arterious ſhoots going out of the* Os Sacrum.
h.h. *Arterious ſhoots into the* Meninga *of the hinder part of the Head.*
i.i. *Arterious ſhoots going out of the Skull with the Nerves of the ſeventh pair.*
k.k. *Shoots reaching out into the wonderful Net, which in their progreſs are ingraffed mutually among themſelves, and alſo with the Arteries Carotides.*

FIGURE

Fig. I.

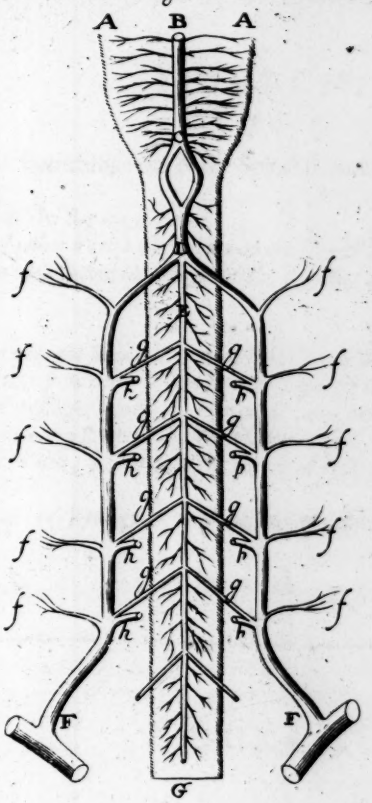


Fig. III.

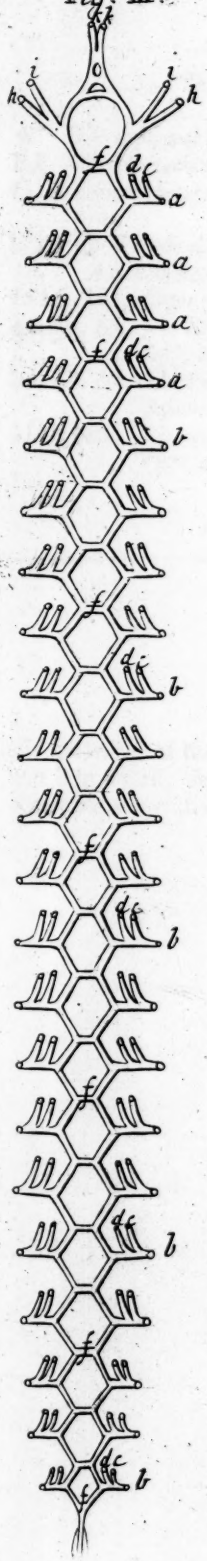

Fig. IV

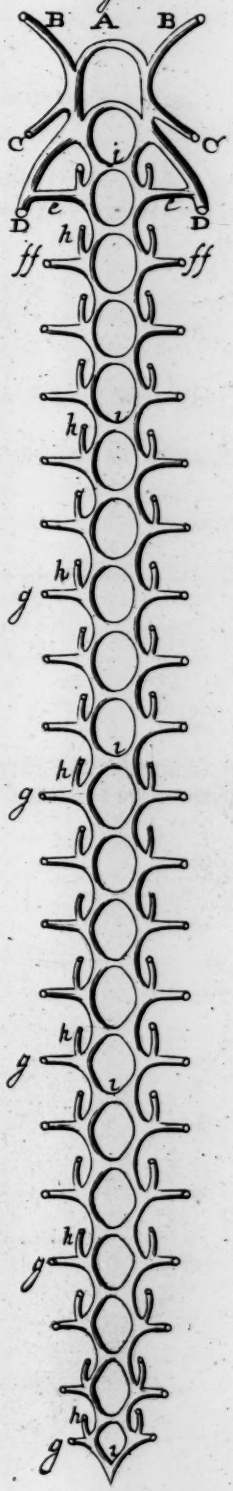

Fig. V

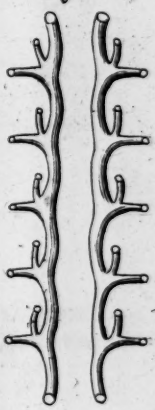

Fig. II.

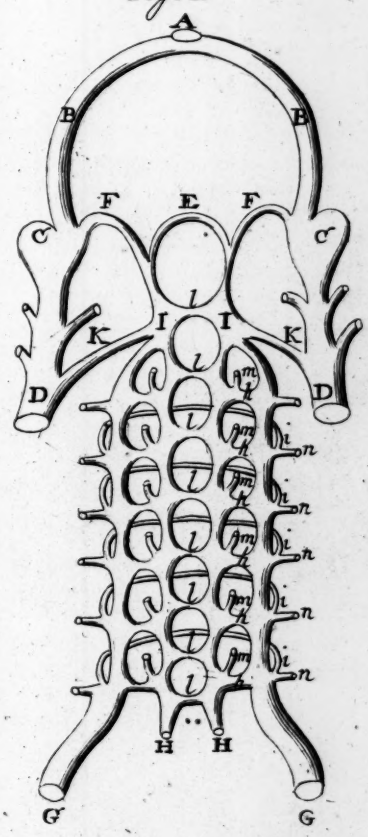

FIGURE IV.

Shews the Branchings out of the Spinal Boſom in its whole paſſage.

A. *The uppermoſt joyning of the Boſoms of either.*
B.B. *Chanels reaching out of either Vertebral Boſom into the lateral Boſoms of the Head.*
C.C. *Chanels brought from the common concourſe of the Boſoms, and the Vertebral Veins into the Jugular Veins.*
D.D. *The Vertebral Veins.*
e.e. *A communication between the Spinal Boſom and the Vertebral Vein.*
f.f.f.f. *The paſſages of the Veins from either Boſom into the Trunk of the Vertebral Vein.*
g.g.g.g. &c. *The like Venous paſſages which are continued lower into the branches of the Vein* Azygos, *and laſtly into the lumbary ſhoots of the* Vena Cava.
h.h.h.h. &c. *The Pipes of the Veins, which receiving the blood from the Spinal Marrow carry it back into the Boſoms.*
i.i.i.i. &c. *The commiſſures or joynings of the Boſoms of either ſide nigh the ſeveral joyntings of the* Vertebræ.

FIGURE V.

Shews the Image of the Spinal Boſom in a Dog, which hath not joynings together in its whole paſſage, as it is in a Calf, Sheep, Hog, and many others, but only in the loweſt and uppermoſt part, where it communicates with it ſelf by three or four croſs Proceſſes.

The

THE CONCLUSION.

THUS much for the Anatomy of the Brain and Cerebel, and of their Appendix, both Medullar and Nervous, and of the Uſes and Offices of all the ſeveral parts, of which we have largely treated. There yet remains, after we have viewed, not only the outward Courts and Porches of this Fabrick, as it were of a certain Kingly Palace, but alſo its intimate Receſſes and private Chambers, that we next inquire into, what the Lady or Inhibitant of this Princely place may be, in what part ſhe doth chiefly reſide, and by what Rule and Government ſhe diſpoſes and orders her Family. Then we ought to take notice, what defects and irregularities happen to it, or to its parts and powers; then to what injuries of changes or Diſeaſes this Building or Houſe, to wit, the Brain and nervous Stock, may be obnoxious. For indeed I am as it were bound, by reaſon of the Work it ſelf, and the promiſe I made before, that for the Crown of the Work, a certain Theory of the Soul of Brutes ſhould be added after the naked Anatomical Obſervations and Hiſtories of Living Creatures, and of their animated Parts. Truly it is but juſt and equal, that we enter upon this Diſcourſe of the Soul, and that other task of *Pathologie*, to wit, that the Aſperities and hard ſenſe of our already inſtitued *Anatomy* may be ſweetned with thoſe kind of more pleaſant Speculations, as it were cloathing the Skeleton with fleſh; and that the Reader being wearied by a long and troubleſom Journey, may be a little refreſhed and recreated. For in truth, whatſoever of our Work is performed without form or beauty, may ſeem as the Foundation of a Building only placed on the Ground, in which no elegancy or neatneſs doth ſhine, but that all things appear rude, and as yet built of rough and unpoliſhed ſtones. A ſuperſtructure indeed may be promiſed to be put upon this Foundation, perhaps fair and beautiful, whereby the minds of the Beholders may be pleaſed and inſtructed. But truly this kind of work may be too hard and great to be performed by our weakneſs; neither doth it become me to proceed in my undertakings, before theſe have undergone the Cenſure and chance to which they are ſubject. For I fear, leſt this Foundation, but now laid, ſhould become too weak and feeble for the ſuſtaining an higher Fabrick, at leaſt until this hath for ſome time undergone the tryal, by lying open to winds and ſtorms.

FINIS.

AN

ESSAY

ON THE

PATHOLOGY

OF THE

BRAIN

AND

Nervous System

IN THE

Convulsive Diseases

As Treated of

Being the Work of THOMAS WILLIS, of Civil-Law in Oxford, Doctor in Physick, and Naturall Philosophy in that Famous Academy.

Translated out of Latine into English, By S. P.

LONDON.

Printed by A. M. and R. R. for T. Dring, J. Adgar, and C. Harper;

The Authors Epiſtle Dedicatory,

To the Moſt Reverend Father in Chriſt, His Grace, Gilbert, *by Divine Providence Archbiſhop of* Canterbury, *Primate and Metropolitan of all* England, *and One of His Sacred Majeſties moſt Honourable Privy Council.*

IT is ſo Ordained by the Laws, moſt Noble Prelate, that whatſoever ſhall happen to be built upon any ones ground, it ſhall be his own by right of acceſſion. Since therefore, to that work which I lately attempted, concerning the Gifts and Nature of the Senſitive Soul, as alſo the Affections of the Brain and Nervous ſtock, and the various Diſeaſes which belong to them, I had placed the Anatomy of the humane Head for a foundation; it was altogether neceſſary (this Treatiſe being Dedicated to your Grace) that whatſoever building ſhould be raiſed on that Foundation, ſhould truly and rightly be ſaid to be yours: And ſo indeed, we continue the fault we had ſometimes Committed; and it becomes not only a ſtep, but what is more, an oligation to the following Crime; that at length, we ſeem rather to perform a Duty, the name of a fault being loſt, than to become Criminal.

But in the mean time, this matter in which I buſie my ſelf, may not be ſaid to be unfit for your Knowledge, or to be diſagreeing to the buſineſs of the Church, over which you moſt happily preſide; For both thoſe Epilepticks which are to be met with here, precipitating themſelves into the water or the fire, and thoſe whoſe members variouſly contracted and diſtorted with Spaſms or Convulſions, and thoſe whoſe whole Bodies ſo bent, that they could not ſtand upright; by and by, as if by Inſpiration of the Divil, they are agitated with Stupendious leapings, and other wonderful geſticulations: Theſe, I ſay, and many other Sick men whom I here every where deſcribe, ſeem not much to differ from thoſe whom we read of in the Evangeliſts to be cured by our Lord Jeſus Chriſt; and although ſuch be to be cured, however contumations and rebellious they are, the Phyſitian, however Skilful he be, ought always to implore the help of the Heavenly Power, to be aſſiſting to him, being above all the Strength of Medicines. Therefore, and by right the Diſeaſe by the Ancients called

Holy

Holy of the word *Theoria*, and the reſt of our Pathology, as if it contained in it a certain Divinity, explicates the Diſeaſe to be cured no leſs with prayers and faſtings, than with Medicines, and therefore ſhould deſire greatly to call upon the Authority of Holy men, and to be helped by the Power of your Sanctity.

Beſides, it is no new thing that there ſhould be an Entrance into the Church thorow the Spittle; for that it appears, our Saviour to have uſed almoſt this method, who would for the moſt part, that the health of the Soul, ſhould take its beginning from the reſtored health of the Body. And truly, as the Stupid *Diliriums* of Melancholicks, the Caniniſh madneſs, and others ſprung from an infirm Brain, have driven ſome, both from the Communion of Saints, and from the Society of men, if theſe had been profligated by the help of our Art, it would not be deſpair'd of but that the men ſhould not only, growing well, have left both at once their Diſeaſes and Errors, but alſo ſhould have become wiſe.

It remains, that I Supplicate the Great God, That he will render to his Church, the peace he has happily given to the Commonwealth, that he may take away the darkneſs from the eyes of the miſerable people, that he may withdraw the fury from their minds; and for a pledge and advantage of ſo great a benefit, that he may long keep ſafe and in health, your Grace, the mighty Pillar and Glory of the Reformed Religion, which is Cordially deſired by,

Your Graces moſt humble

and Devoted Servant,

T. W.

OF

Of Convulſive Diſeaſes.

CHAPTER I.

Of Spaſms or Convulſive Motions in General.

IN handling the Convulſive Diſtempers, many Phyſitians diſtinguiſh between the *Spaſme* or *Convulſion*, and *Convulſive Motion*; by the firſt they underſtand a conſtant Contraction, whereby the Member becomes ſtiff and inflexible; by the Second, ſwift motions, and Concuſſions, which, coming between, ceaſe, and return alternaetly: But neither thoſe who have obſerved theſe notes of difference, nor other Authors, have taken notice that they are continual: for that by the words *Spaſme*, and *Convulſion*, they often deſign a certain Spaſmodick or Convulſive Affection; wherefore to diſtinguiſh it better, we will call the former diſtemper with *Cardan*, Tetanon, a continual Convulſive Cramp; but the other *Spaſme*, or a *Convulſive motion in general.*

But that the irregular Nature and Cauſes of Convulſive motion, might more rightly have been made known, it ſhould firſt have been declared, after what manner the regular motive function is effected in an animated body: but the more full Conſideration of this, becauſe it belongs to the Phyſiologie, or Reaſoning of the Nature of the Brain, and Nervous ſtock, it is deferred to another Diſcourſe: For the preſent, we will ſignifie in a word, as much as ſhall ſerve for the elucidation of the matter propoſed. That the animal Spirits are the next inſtrument of regular motion, and that their Action, or moving force, conſiſts only, in that they being more thickly heaped up together, in the motive part, and there ſpreading themſelves in a more large ſpace, they blow it up, and intumeſie it; which for that reaſon, being contracted, as to its length, draws to it ſelf the part hanging to it. In our deſcription of the Nerves already publiſhed, we have ſhown this kind of motion to be twofold, to wit, Spontaneous, and meerly natural, the Inſtinct of this is derived from the Cerebel, but of that from the brain, but both through the pipes of the Nerves, as it were the channels, both to the muſcles, and alſo to the fibres, interwoven with the membrains, and other motive parts of the *Parenchyma*, or inwards; Laſtly, in all theſe, the various actions are ſo expeditiouſly effected, which either natural neceſſity, or the rule of the will requires, by that only means, that there is an intimate Conjunction, and communication of Duty, and moſt ſwift Commerce, between the animal Spirits, which conſtitute the *Hypoſtaſis* of the ſenſitive Soul, within the foreſaid parts, diſpoſed, or fitted by a continued *Series*. But there is this notable difference between the motion of a muſcle, and that performed by other parts; for in theſe the action is moſt often circumſcribed within the bounds of the motive body, ſo as its membranes only, or one part of the inward moves another, and conſequently this is moved of its neighbour: But in the muſculous ſtock, uſually the moving part is placed in one member, and to be moved of another next it (although within ſome muſculous part, as the Heart and *Diaphragma*, they properly for the moſt part move themſelves only) hence the Membranes and inwards, are ſaid to have as it were an inteſtine and vermicular Motion; ſuch as whereever it is begun, the Spirits there more thickly gather together, and ſpreading themſelves forth, they firſt intumifie this part, then going forward another, and ſo farther, till at laſt they draw the hindermoſt parts, and by this means transfer an intumifaction, and therefore a motion, from one place to another; almoſt after the ſame manner as worms, and other creeping creatures make their progreſſion. But to this motive function of the Membranes and Inwards, if it be frequent or undiſcontinued, plenty of ſpirits are required, which notwithſtanding execute their task calmly enough, without tumult or great force: And indeed it is to be obſerved, that the Animal Spirits flow not more ſparingly into the Membraneous Inwards, than into the Muſcles; as it appears from the more exquiſite ſenſe of thoſe parts, and by the manifold inſertion of Nerves within them, and the diverſity of divarication, through the foldings and *fibres*, altho in the mean time the muſcles are watered with a more plentiful influx of Blood: But as to the motion, performed in the muſculous ſtock, the heaping together, and rarefaction of the Spirits, through the whole jointing of the mo-

How the regular Motion is Effected.

Its beginning twofold.

The Subject alſo twofold.

tive part, suddenly and unfolded, are performed with such force, and strength, as the attraction of the muscle, in its motive endeavour, may exceed the force of a pully or windlace; and when this force only depends on the expansion or rarefaction of the Spirits, seated in the motive part, we conceive it to be no otherwise, but that the Spirits so expansed or stretched forth, as it were fired, after the manner of gunpowder, to be explodedor thrown out. But we may suppose, that to the spirituous Saline particles, of the spirits inhabiting the interwoven *fibres* in the muscle, other nitrous sulphureous particles, of a diverse kind, do come, and grow intimately with them, from the arterous blood, flowing every where within the same *fibres*: Then as often as the particles of either kinde, as *Nitre* and *Sulphur* combined together, by reason of the instinct of motion brought through the nerves, are moved, as an inkindling of fire, forthwith on the other side bursting forth, or being exploded, they suddenly blow up the Muscle, and from thence cause a most strong drawing together; for indeed it seems to be ordained for this end, that the Muscles are imbrewed much more plentifully with the arterous blood, than the membraneous inwards; to wit, that the Elastick coupling of the spirits, being consumed, and perpetually falling off, through the very often, and sometimes continual motion, might be by that means supplied, from the fresh sanguineous juice: in the mean time, that the spirits themselves, being supplied in a smaller quantity, through the small nerves, might even like old Soldiers continue longer in the same station, and follow their manifold coupling or labour. How else are labouring beasts supplied with a sufficient stock of spirits, for so much labour; whilst they exercise almost all their muscles, by a swift course for many hours, yea sometimes a whole day? or who can believe that a little handful of spirits brought through the small branches of the wandring and Intercostal pairs of the Nerves to the heart, can be able by their own strength to effect that its so strong and indiscontinued motion? Indeed it seems, that of necessity there must come to them from the blood perpetually, auxiliarie aid, and those afterwards to be always exploded. For this reason certainly, the motive virtue, both of the Heart, and the rest of the Muscles, becomes more strong and Elastick, above any mechanick Organ: to wit, for as much as the animal spirits, acting every where in the musculous stock, get to themselves an explosive *Copula.*

The Motion of a Muscle is a certain explosion of the spirits.

If any one shall be displeased at the word *Explosion*, not yet used in Philosophy or Medicine, so that this Spasmodick Pathologie, standing on this *basis*, may seem only *ignoti per ignotius explicatio*, an explication of unknown things by more unknown things; it will be easie to shew the effect of this kind of notion, and very many examples and Instances both concerning natural and artificial things, from the Analogie of whose motions, in an animated body, both regularly and irregularly performed, most apt reasons are to be taken. For besides the mixtures of *Nitre* with *Sulphur*, with *Tartar*, and with *Antimony*, all which are fired with a thundring noise; also *Aurum fulminans* or *fulminant Gold*, and a Composition of salt of *Tartar*, with *Nitre* and *Sulphur*, without any actual fire, being only thoroughly heated, are exploded with a vehement Crash; also to this may be referred, many Liquors, which being mixed together, or poured upon some certain bodies, cause or stir up violent motions, and plainly explosive: The spirit of *Nitre*, and the Liquor of congealed *Antimony*, being poured on one another, or either of them thrown upon the filings of Iron, cause a great *Ebullition*, with heat and black Smoke. It is commonly known, what heat or effervescency, and force plainly explosive, arise from fixed Salts melted together, and from acetous or sharp salt of every kind, mixed with one another: Nor is the effect of Explosion less seen, when a liquor imbrued with a volatile Salt, as the spirit of Harts-horn, or of blood, is put to a saline, either fixed or acetous *Stagma*, or sulphureous *Nitre*, to wit, the particles being vehemently stricken one against another, leap up with a force, and on every side are carried forth, a great way; which without doubt, if they were restrained within the space of any body, as the fibres of a Muscle, they would suddenly intumifie it, and so would constitute an instrument of local motion. Concerning this thing, we have more fully discoursed already in our *Neurologie*, or Tract of the Nerves, and perchance we may yet publish the explication of this more fully and more acurately some other time.

In the mean time that this opinion may not be thought altogether new, and that I have exposed it as a child of my own brain, that had no other Patron, I will here shew you the assertion of the famous *Gassendus*, which as it openly favours our Hypothesis, and in some sort gave an occasion of it; so, perhaps it will give to it some Authority. *Therefore this Rational man, weighing in his mind, how much that force or strength might be, with which not only the Arm, or Thigh, but the whole animal Machine, is moved, govern'd, lifted up, and carried up and down: He adds, Who can easily comprehend that small thing, whatsoever it is, within the body of an Elephant, whether we conceive it to be a soul, or spirit, or any other beginning of motion, that it should be able to agitate such a bulk, and to cause*

cause it to perform a swift and regular dance? and so much the more, for that, when as that small thing within that body, no longer flourishes, there is need of somuch outward strength to remove it never so little from its place: but indeed, the same fiery nature of the soul, serves within the body, by its own mobility, the same thing in proportion, that a little flame of Gun-powder does in a Cannon: whilst that it not only drives forth the Bullet, with so much force, but also drives back the whole Machine with so great strength. But indeed he says as to the spirits, which (like exploded Gun-podwer) cause the agitation, it is doubtful whether it be they which come from the brain, or those in the little tendons as it were of kin to them, or springing from them, that are thought to do it: But altho either of them concur, yet they seem to be more presently destinated to this office, which are those of the same kin or off-spring in the Tendons. There needs no more, it is declared, that the motive function depends on the *Elastick Copula*, of the animal spirits, and its decision or abating. But from this being supposed, (which indeed we may suppose with very great probability) it easily follows, that the convulsive motions proceed from the like cause: For whosoever shall consider the sudden puffings up, the violent and strong Contractions in the members and affected parts, yea, sometimes the most impetuous concussions, and violent throws of the whole body, can conceive no less, than that very many heaps of the animal spirits are exploded, or thrust out, even as lightning breaking forth from a Cloud. Further from hence it may be Argued by a reciprocal Argument, that because the Spasmodick motions are explosive, that therefore the regular are also produced by the explosion of Spirits: But after what manner, and by what means, and from what causes, the animal spirits being exploded, or thrust forth, produce Spasmodick Affections, shall be our present business, a little more largely and plainly to demonstrate, however difficult and abstruse the matter seems to be.

The Conjunct Cause of Spasms.

We will not here stand to recite many opinions of others, concerning the Nature and causes of a Spasm, or Convulsion; that which was most common, and long famous among the Ancients, that this distemper was only produced from repletion or inanition, or from fulness or emptiness, (however, besides the authority of *Hipocrates*, for the establishing of this, an example is brought, of a Skin, or the strings of Lutes, which are wont to be contracted, being either filled with a moist, or emptied by too dry an air) easily falls of it self; because it seems to suppose (that which is credible to none by Experience, the fragility of a *Nerve*) to wit, that the *Nerves* themselves, after what manner so ever *abreviated*, and contracted, are able with a certain force to draw to them the Muscles. If that it shall be said, that the repletion or inanition, ought to be understood, in respect of the solid parts, which were wont to be drawn together; it may be observed to the contrary, when as the Muscles and Nervous stock are very much watered with a watery humor, as in an *Anasarca*, or are plainly destitute of the same, as in the consumption, or Mirasmus; yet no convulsive motions are for that reason excited: among the moderns, very many have determined irritation of the Nervous parts to be the cause of Convulsion; taking their Conjecture from thence as I suppose; for that by ocular inspection it appears from the Vellication it self, and by the only touch of the Nerves, that spasms are induced: And indeed we have clearly observed in the dissection of a living whelp, that the knife being put upon the naked ends of the spinal Nerves, presently both themselves, and the Bodies of the Muscles in which they were inserted, were hauled: neither is it unusual, that spasms are excited almost in every man, by the punctures of the Nerves and Tendons. I remember by reason of an Ulcer in the arms of a certain man, that the Tendons of the Muscles were laid open, which when touched by the Surgeons Instrument, caused in the Patient a certain rigor through his whole body, and forthwith a Concussion arising, made him to quake for a good space. But in truth, albeit we grant the irritations of the Nervous parts, not seldom to serve the turn of the evident cause; and further that sometimes this solitary cause produces more light and transient spasms; nevertheless, that the more grievous paroxisms of this Disease, and their frequent repetitions by turns may be duly unfolded, it behoves us to investigate, or search out other and deeper causes, to wit, the conjunct and procatartick Cause.

Not repletion or fulness, or inanition or Emptiness.

Forasmuch as spasms never happen but in a living Body, where the Nervous parts are blown up, and grow turgid with the animal Spirit, we may readily conjecture that those animal Spirits themselves are as in regular motion, so also in the Convulsive, the next Instrument of Action: to wit, so long as they are imbued with a fit and moderate explosive *Copula*, and are moved to that striking forth, only by the command of the Appetite, or instinct of nature, they bring forth motions altogether regular; but if the same Spirits get to themselves an heterogeneous *Copula*, and too much Elastick, or if they are snatched into their Actions more impetuously and vehemently than they should be; they even like unbridled Horses, pricked forward with Spurs, leap forth inordinately, or throw off, or explode violently their *Copula*, altho genuine and natural: and so

There is a double Cauſe, and two kinds of Spaſms. Irritation.

they carry away the containing parts, as it were a Chariot tied to them, together with themſelves, with a fierce and perverſe motion.

When therefore, as aforeſaid, the Convulſive motions are chiefly ſtirred up for two Cauſes, hence as many *Species* of them are ordained. For firſt, it happens that a Convulſion is induced without a procatartick Cauſe, or heterogeneous *Copula*, firſt acquired only from a ſolitary evident cauſe: For ſo a vehement paſſion, impreſſed on the brain, a diſſolution of the parts, hapning ſomewhere in the Nervous ſtock, a ſpaſmodick paſſion is ſuddenly brought upon ſome, whoſe brain and Nerves are of a more weak conſtitution: for that the animal ſpirits do trouble the containing parts, the improportionate Object flying from them, and by ſtriking vehemently their *Copula*, though very agreeing, it blows them up, and ſo they pull others annexed to them: Spaſms being after this manner excited, becauſe the natural *Copula* of the ſpirits in them is ſtricken more vehemently, they are after a manner exploſive, which notwithſtanding, quickly leave off, and very often paſs away with moving of the Viſcera, or Members; only with a trembling, and ſome horror, into a fainting of the ſpirits. But Secondly, Convulſions, whoſe paroxiſms are more grievous, and ſtay longer, or are oftener repeated, ſeem altogether to depend on a procatartick cauſe, or a previous diſpoſition, and to ariſe from ſome other conjunct cauſe, beſides Irritation. And therefore in this caſe we

A preternatural exploſive Copula.

ſuppoſe, that the heterogeneous, and greatly exploſive particles, do increaſe with the ſpirits, acting in this or that region of the Body: then from this wicked Combination, and reſtleſs Colliſion of this kind of matter, and the ſpirits frequent and vehement exploſions being brought forth, the ſpaſmodick Paroxiſms are induced.

But beſides the Elaſtick *Copula*, which every where happens to the ſpirits, from the arterous Blood, and from whoſe orderly exploſion the motive force is performed, according to the Book of the Appetite, or inſtinct of Nature, in all the Nervous parts; (as we have elſewhere declared) alſo ſometimes other kind of little bodies, of a fierce nature, or rather like *Gun-powder* or *Nitre*, come to the ſpirits, and intimately adhere to them, when frequent and ſuddain divorces of this matter, from the Embraces of the ſpirits, happen from the mutual ſtriking together of the particles, the containing Bodies are variouſly blown up, and ſo are thrown into Convulſive motions. In truth, as often as the Spaſmodick Affection becomes habitual, that the Convulſive Paroxiſms ariſe not rarely on their own accord, and without any evident cauſe, but ſtill on every light occaſion; the procatartick cauſe of ſuch a Diſeaſe, conſiſts in the evil diſpoſition of ſuch a ſort of animal ſpirits: For neither is the Serous filth, or other leſs ſharp humours, although depoſited in the very ventricles of the Brain, or about the origine of the Nerves, ſufficient to ſtir up ſuch a ſickneſs: For that I have ſeen in the heads of dead people, oftentimes the middle part of the Brain, and the very beginnings of the Nerves, wholly covered with a limpid water, who, whilſt they were alive, had neither the Epilepſie, nor Convulſive Motions: But to the producing of theſe motions, very active Bodies are required, ſuch as are Saline, and Sulphureous, which being combined with the ſpirits, and then on a ſudden breaking from them, they imitate the combinations and violent exploſions of particular Minerals. For indeed, if in regular and ordinary motion (as we have intimated) the Muſcles cannot get a motive force, and elaſtick ſtrength, unleſs a certain exploſion of the animal ſpirits be ſuppoſed, certainly much more lawfully may we aſſert, that epileptick fits, and other admirable Convulſions, which ſtill happen to be excited, complications of the ſame ſpirits, with other very fierce particles, and vehement eliſions, or ſtrikings of theſe one againſt another, are required. But, as to this kind of Spaſmodic *Copula*, becauſe it differs from the natural and ordinary, which we have elſewhere ſhewn to be in regular motion, and to be ſupplied from the blood; it behoves us to inquire from whence it comes, and by what means and in what places it is wont to get to the ſpirits.

As to the firſt, it is to be obſerved, that Spaſmodick exploſions do every way happen, in the Muſcles, to which only they are limited, which effect the regular motion; but alſo in the Membranes, to wit, the Ventricle, Meſenterie, and other parts almoſt without blood: beſides, that the exploſions themſelves, in the Convulſive Affection, though they are excited contrary to the will of the Appetite, and the manner of Nature, are far more vehement, and do longer continue, than in the irregular motion: out of which it ſeems to be manifeſt, that the Exploſive Spaſmodick *Copula*, doth come from ſome other place than the Effectrice of Legular motion: And indeed, it is probable, that that flows not, as this, from the arterous blood, running every where among the Muſculous *fibres*, but deſcends from the Brain, with the Liquor watering the Nerves, and ſo is heaped up, about their beginnings, middle, proceſſes, enfoldings, and Extremities, as it were the Mine of the Convulſive Diſeaſe. Indeed nothing

The exploſive Spaſmodic Copula, *not immediately from the Blood, but from the Brain.*

appears

appears more evident, than that the Spasmodick Disease doth most often arise by reason of the evil first fixed in the Brain, and from thence is transmitted into various parts of the Nervous System: for it happens from hence, that a vehement Passion, as of Fear, or Anger, or of Sadness of spirit, affecting the inhabitants of the *Encephalon*, the passion called Hysteric, and Hypochondriac, doth so often arise: Further, that in the evil Crises of Fevers, when the adust recrements of the blood are transfer'd into the head, Convulsions do generally succeed. Moreover, and this is the reason, why the Vertigo, the inflation of the head, torper of the mind, and other accidents of the Supreme Region, are wont to be the *proæmium* of Spasms presently following in the Inwards, and not seldom in the whole Body. Wherefore it is not to be doubted, but that the heterogeneous and explosive particles, are instilled from the Blood, together with the Nervous juice, into the Brain; which afterwards being thrust forth into the Nervous stock, do there grow to the spirits, and with them bring on a Convulsive disposition. In truth, the Spasmodick distempers, which are either universal, or at least occupy many parts of the Body at once, arise for the most part, by this only means. But in the mean time, we will not deny but that particular Spasms, which contain themselves within certain places, the dead being no ways affected, are induced sometimes by other means. For if the Nerves imbibe their humour from either end, to wit, the root, and the extream fragments, (which both the learned *Glisson* maintains to be most likely, and by us is shewed in our Neurologie, not without great probabillity) it may be from hence inferr'd, that the Spasmodick particles are brought inwardly, not only from the beginning of the Nerves, but somewhat also by their extremities: Therefore that perhaps appears clear and plain enough, that from the Spleen being evilly affected, Spasms arising about its Region, do not seldom affect the *Hypochondria* and *Præcordia*. I have known some, from a Tumour or Ulcer existing in the Mesenterie, Womb, and other inwards, were wont to have Convulsions both in the grieved part, and also all about it; the reason of which seems to be no other, than that the heterogeneous particles being more plentifully heaped up in the affected place, creeping also into the Nervous *fibres*, planted nigh thereunto, supply them with matter for Convulsive motions like to fired Gun-powder: But indeed, Spasms arising from such a cause, are not wont to diffuse themselves far about, nor always to ascend to the Head.

Sometimes received from the ends of the Nerves.

These things being thus premised, concerning the inward and next cause of the Spasmodic Distemper, which we affirm to arise chiefly, and most often from the head it self, and in some respect also from the extremities of the Nerves; it now remains, that we more particularly declare, the various remoter Causes in either kind, and the manifold provision of this Disease. The Convulsive Disease therefore, for the most part, takes its Original from the head: to wit, as often as the heterogeneous and explosive particles, being diffused from the Blood into the Brain, or its medullarie Appendix, are afterwards derived to the Nervous stock, and there grow together with the spirits: But this happens to come to pass from various causes: for there are very many ways and means whereby the Morbifick matter is admitted into the head, and very many also, whereby it is deduced into this or that region of the Nervous System; and according to the various Translations of this kind of morbifick matter, the divers kinds of Convulsive motions are constituted.

The more remote causes of Spasms.

Therefore, that the Heterogeneous and Spasmodic particles are admitted into the Encephalon, it is to be imputed to the fault both of the Blood sending, and of the Brain receiving it.

1. The morbifick matter is heaped up within the Head, by the default both of the blood sending.

1. When the Blood pours upon the Head the Morbifick matter, either all its whole mass is depraved, as it frequenly happens in malignant Fevers, also in the Scorbutick, Cacochymick, and chiefly in an Originally corrupt Distemper; or the Blood of it self innocent and incorrupt, receives elsewhere Malignant little bodies, and afterwards fixes them on the brain; so in great impurities of the Inwards, and chiefly when any parts are affected with an Inflamation, or virulent Ulcer, or hurtful Ferment; for from such Mines the taint of the Disease, the noxious particles, bubble up into the Blood, and afterwards, in its passage, are laid up in the Brain: So, by that reason the Spleen, Womb, and other Inwards, being evilly affected, Convulsive Diseases are excited, which notwithstanding, depend more immediately upon the Brain, receiving the corruption of those parts, through the commerce of the Blood.

And also of the Brain receiving it.

2. But in the second place, the Blood however vitious it should be, and impregnated with the Morbid seed, it could not easily leave its Infection on the head, unless there were some fault in the constitution of the Brain, and its Appendix; as long as these parts are well made, and are full of vigour, they defend themselves, and what belongs to them; and the doors being shut, they admit nothing but an unmixt spirituous Liquor,

quor destinated for their use: but if either the passages and pores of the Brain are too lax, or the door keeping spirits leave, or are called off from their watches, and Heterogeneous and Morbific matter creeps in together with the Nervous juice, and unfolds its malignity in the animal government. As to the evil disposition of the Brain it self, it is sometimes hereditary: So those sprung from Parents obnoxious to the Epilepsie, or Convulsions, are themselves for the most part prone to the same Distempers: and indeed, the constitution of the Brain may several ways become vitious from the birth: for either its temperature is more moist, or more dry than it should be, or it may be faulty by the excess or defect of either quality. Sometimes the pores are more lax, or its consistency is too soft, or too hard: and also the Conformation of the parts of the Brain, and its Appendix, may be after an undue manner; But sometimes, the disposition of the Brain and Nerves, originally whole and firm, is vitiated by accident, and acquires a Morbid inclination: long Intemperance may enervate these parts: as also Malignant Fevers, and Chronical Diseases, very much debilitate them: besides outward accidents, as the excess of heat or cold; an Ulcer or a blow oftentimes perverts their Crases, and renders them more incident to the impressions of Diseases. But as to the constitution or irregularities of the animal spirits, by reason of which, the Heterogeneous and Spasmodic particles enter the Brain without any repulse, and more easily cleave to it; it is to be observed, that the animal spirits are in some more tender, and easily dissipable from their very birth; so that indeed they are not able to suffer any thing very strong or vehement to be brought to the sense or imagination, but straight they fly into confusions: For this reason, women more than men, and some of them more than others, are obnoxious to the passions called Histerick. Further, sometimes a violent Passion impresses on the spirits, though moderately firm, this kind of dissipation and inordination, so that afterwards they are able to suffer nothing strongly, or to resist any injury: So it often happens, that Morbid impressions are affixed on the animal *regimen*, by sudden fear, or great sadness, which can hardly ever after be blotted out: for from hence Women often contract first the Diseases named the *Mother*, or from the *Womb*; and Men the *Hypochondriack*, and are for the most part still subject to them.

The evil disposition of the brain is either hereditary,

Or acquired.

From these things it appears, after what manner, and for what causes, the Spasmodic Matter is wont to be admitted into the Head: now let us see next what is done with it afterwards; if that this matter brought to the Brain, induces the Convulsive Distempers, either not always, or not altogether after the same manner.

2. *How the Morbific matter being admitted within the head is disposed.*

1. It sometimes happens, that the Heterogeneous and Explosive Particles are admitted into the Brain, which notwithstanding are again exterminated without any great hurt, and before they enter into the Nervous stock: for that the Veins and Lympheducts, or water-carrying Vessels, often sup up what is superfluous, and an enemy to the animal dominion, and convey it forth of doors, or dispose of it into Emunctuaries, or Sinks. Whilst such a Matter is for a little while agitated in the Brain, its Particles being affixed to some of its Spirits, and at length striking against them, cause the *Virtego*, and the swimming in the head; but because they enter not into the passages of the Nerves, Spasmodic Distempers do not follow.

Sometimes it is carried back again from the brain.

2. When the Morbifick Matter is admitted within the Head, and not presently from thence sent back, oftentimes it produces not its evil, till it is inserted into the stock of the Nerves; for the animal Spirits within the Brain, being as yet strong, and having got a more free space, they evade the embraces of every Heterogeneous *Copula*; which indeed they are not able to do within the strait channels of the Nerves: Besides, the Morbifick Matter it self, if it cannot be sent away out of the Brain by the excretory Vessels, it is by and by sent forth to the System of the Nerves, as the more ignoble part; but if in spite of the force of the superior faculties, such a matter stays long within the Brain, it much infects the spirits that inhabit it, and induces the *Epilepsie*, as shall be more particularly shewed hereafter: but more often, the hurtful matter is thrown on the Nervous stock, from the Brain, without much harm to it; but this happens to come to pass not always after the same way.

Sometimes it is thrust out into the Nervous stock.

Remaining in the brain causes the falling-sickness.

For truly, the Heterogeneous Particles, being mixed with the Nervous Liquor, and fallen towards the beginnings of the Nerves, do not indifferently enter all of them together, or these, or those, as chance shall guide them, but they are directed to the passages of some before others, and that not without some Reason. For we observe, that the Convulsive Symptoms do chuse for the most part one place in Children, another in riper years, and a different one in more tender, than in the more robust.

The Spasmodic matter being fallen on the nervous stock

In

In Children, who are not yet accustomed to the Affections of the Heart, and exercise of the outward members (whereby the Morbifick cause may be further carried from the brain) the Spasmodic matter runs more often into those neareſt Nerves, *viz.* the third, fifth, and sixth pares; wherefore, their faces and mouths, and those parts are chiefly handled: and it is rare and unusual for them to have their *viscera*, and *præcordia*, lifted up, or affected, with an inordinate motion, as in those of riper years: on the contrary, in men of more advanced years, by its approach to the intercostals, and the Nerves of the wandring pare, it being more open to those of the spinal marrow, which those Nerves respect, are wont to be more frequently pulled: but yet with this difference, that in the more tender, and those who are very delicate, and subject to passions, and who by reason of the passions of the mind, have very often their *præcordia* and *viscera* disturbed, the Spasmodic matter more readily enters the more open passages of the interior Nerves, and therefore they are rendred more obnoxious to Spasms, stirred up in the *Abdomen* and the *Thorax*: for hence it is that Women are molested with the Passions called Hysterical, and some men with the *Hypochondriack*; as shall be more largely declared hereafter, when we come to treat particularly of these Distempers.

Afflict the fore-parts of the Nerves in Children.

Otherwise in those of riper years.

When the Spasmodic matter falls upon the heads of some Nerves, or remaining there, it creates only a giddiness, and lighter *Spasms*, and leapings of those parts to which these Nerves belong, or being slidden more deeply into the pipes of the Nerves, it brings forth more cruel Convulsive Paroxisms: but the same being dilated into the Nervous processes, is disposed through one or more of the branches of the stock or trunk, sometimes all, and sometimes only those more open than the rest, and by degrees cleave to the spirits, both within those Nerves, as also to those planted within the hanging *Fibres*: so that it is after the same manner, and there is the like preparation in the disposition to Convulsive *Paroxisms*, as if grains of Gun-powder were laid in a long train to be fired successively: The spirits after this manner imbred with an Heterogeneous *Copula*, are lodged within the *Fibres*, interwoven with the Membranes and Muscles, but chiefly within the Nervous foldings; and when they grieved with too great plenitude, or troubled on any other occasion, are compelled to shake off their *Copula*, the Particles striking and leaping one against another, hugely blow up the containing parts; and so excite a motive force, contrary to the commands and laws of the Appetite and Nature: Besides, the spirits once stirred up to the performing Convulsive motions, begin their Explosions from the one or the other extremity of the Nervous System; but for the most part at the end. But they who are first exploded snatch or take with them their neighbours, also prediſposed like a fiery train; and so they propagate the begun affection, with a long continued *series* of Spasms, from one end to the other: For a Convulsion begun in the bottom of the belly, or at the foot, or hand, creeps by degrees to the upper parts, and for the most part to the head it self: and the same Distemper when it begins in the brain (as in the Epilepsie) is derived in like manner thence downwards, to the remote Viscera, and also to the exterior Members and Limbs.

After what manner it disturbs the spirits, whilst it stays near the beginning of the Nerves, or being fallen more deeply into their passages.

The spirits enter into explosions, by reason of plenitude or irritation.

The Morbifick matter, flowing in the heads of the Nerves, produces divers kinds of convulsions, according to their various plenty and dispensation; For first of all, it is to be observed, that the whole passages of the Nervous System, or of some of its parts, through the abundant and exuberant matter, are sometimes possessed, so that the animal spirits both flowing in, and there implanted, being full of an Heterogeneous *Copula*, and a perpetual supplement of it, are urged into continual Spasms. I have known some who have had all the Muscles and Tendons through their whole Body afflicted with contractions and leapings without intermission: I have known others whose Thighs, Arms, and other Members, were perpetually forced into various bendings and distortions: and also others I have seen, who of necessity were compelled to leap and run up and down, and to beat the ground with their feet and hands; and if they did not, they fell into cruel Convulsions of the *Viscera* and *Præcordia*. 2. If the Explosive and Heterogeneous Particles be combined with the spirits in a lesser plenty, they stick to them without tumult or perturbation, until, after some time, both Particles leaping again one from another, and from their striking one another, raise up Convulsive Paroxisms; which sort of Paroxisms are periodical, and are repeated exactly at certain hours; which happens by reason of the Morbifick matters being dayly poured upon the Nervous stock, with an equal dimension; and therefore about the same space of time it is also daily heaped up to an explosive plenitude; or they are wandring and uncertain in others, for that the Heterogeneous Particles are poured in with a lesser company, and so arise not to an explosive fulness under a long time; when in the mean time, the more full heaping of them together, and their explosion,

The Spasmodic matter causes Convulsions, either continued, or periodical, or by fits.

are

are wont to happen sometimes more often, and sometimes more seldom, by reason of several occasions, or evident causes: hence it comes to pass, that the Spasmodic Distemper is sometimes altogether attributed to the evident cause; when indeed, if a more remote Convulsive cause had not gone before, such a cause had stirr'd up none.

The evident causes of Spasms.

Therefore, that we may say something of the evident causes of Convulsions, we have already observed, if they be more vehement, and happen to a weak and tender constitution of brain and nervous stock, they are sometimes solitary, or of themselves cause Convulsive Passions: but as often as the Spasmodic Distemper is heavier, and being made habitual is wont to return oftener, though the evident cause be manifest, and bears the blame of the effect, nevertheless it is to be suspected that a procatartick, or more remote cause exists, and is the more strong efficient, though it lies hid within: for unless the spirits are imbued with an Heterogeneous *Copula*, they would not be so easily nor so often driven into involuntary and preternatural Explosions.

The Evident Cause twofold viz. Filling and Irritateing.

We meet with a double order or *Classes* of Evident causes; for either they are of that sort which increases the procatartick or more remote, and brings it sooner to an explosive fulness, as are an ill manner of living, and errors in the six *non*-naturals, which by infecting the blood, and nervous juice, heap up to a Saturity, in greater plenty, on the Spirits heterogeneous particles, and by that means do the sooner procure Spasmodick accessions. Or 2dly, The evident cause is said to be, whatever stirs and irritates suddenly the spirits, that they presently fall into explosions, and whatever it be, that causes them to strike off their *Copula*, and of this sort there are very many accidents, that provoke the spirits, planted now within the Head, and now within the nervous System, to convulsive motions by a divers instinct (as is wont in the regular motions) which motions are either direct or reflected.

The irritating cause stirs up Spasms, direct, or reflected.

1. Of the former kind chiefly are violent perturbations of the mind, wherewith the spirits of the brain being agitated and confused, they excite others lying within the nervous stock, and often prædisposed to irregular explosions; so a vehement fear, anger, or sadness, do not only introduce epileptical and hysterical fits, to those that are disturbed in their health, but sometimes cause to divers others, palpitation, and trembling of the heart, and also horrid convulsions of the members and limbs. 2. As to the other kind of evident cause, to wit, whereby Spasms are excited by a reflected Act, this indeed comes to pass not unfrequently, as often as any heavy trouble, with an irritation of the *fibres* and spirits, happens any where to the nervous stock: for that this trouble being by and by communicated to the chief fountains of the Spirits, to wit, the brain or Cerebell, from thence inordinate and violent motions, against the will of the mind, that is convulsive, being begun, they are returned back, for so either worms, physick, or sharp humours, cruelly hauling the coats of the Intestines, cause spasms in those parts, and not seldom in the outward members.

So much for the several kinds of causes, the conjunct, procatartick, and evident, whereby convulsive Diseases, becoming habitual, and are wont to be repeated with more grievous Paroxisms, do arise: But as we have assigned another species of this Disease, where the Paroxisms depend on an evident solitary cause, or at most only from irritation, the Spirits being not yet præoccupied with an explosive *Copula*: it is now next to be inquired into, by what and how many ways this may come to pass. Concerning this in general, it is affirmed, that the Spasmodick fits produced by mere irritation, are either lighter and quickly passing away, or more grievous, and not seldom deadly, as when poyson is taken, or when they come upon an overpurging medicine. Moreover it is noted, when the morbifick, or irritative matter falls upon the tales themselves, or the foldings of the Nerves, that it also not rarely becomes explosive, and so Spasms produced also from mere irritation (as we have already noted) are certain explosions; these being thus premised, we will dispatch the business in hand.

The irritaiing Cause distinguished, as to the places affected, as to the subjects.

The places affected are the beginnings the extremities, and the middle processes, and foldings of the Nerves.

The irritation of the nervous parts, which is wont to cause convulsive motions, happens in various places, and from various matters, which are incongruous and inimical to the spirits, and *fibres*. As to the things, enemies to the Nature of the spirits, you may observe, besides poysons, and the excess of cangible qualities, which are inflicted from without; many things which are begot within us, *viz.* the various recrements of the blood, and nervous juice, feverish taints, preternatural salt, or sulphureous humors, yea worms, the stone, with many other things, to be infestous to the nervous stock, and ordinarily to stir up Spasmodick irritations. As to the places affected, or the seat of the irritative matter; although this brings hurt in any part of the nervous System, yet for the most part, it is wont to become most infestous, when it is fixed near the beginnings or the ends of the nervous System, or about the middle processes of the Nerves, and especially in their foldings: Besides, such a matter, which irritating the Spirits, is wont to have the place of an evident cause, doth not seldom become, as we hinted but now,

the

the means of a more remote cause, forasmuch as the heterogeneous particles, being sent from it, enter into the nervous fibres, and being combined with the Spirits, renders them more apt and ready to be exploded.

How the irritating Cause affects the origine of the Nerves.

1. Therefore, it sometimes happens, that malignant humours, and infestous to the nervous stock, being poured out from the blood, on the region of the brain, and from thence being dilated to the hinder region of the Head, do fall upon the *origine* of the nerves: where, if the little skin, which cloaths the oblong pith, be broken, they fall into the naked trunks of the nerves, and enter deeply into their fibres; wherefore indeed, *Convulsive motions* arise, not only in the neighbouring parts of the head, but sometimes in very remote, and not rarely in the whole Nervous System: This is generally observed in evil Crises of feavers, the morbifick matter being translated to the head; also in cephallic Distempers, being brought to the worst and deadly state. Truly when I have opened the heads of those who died by this means, I found in all of them the hinder region of the oblong pith, immers'd with a sharp and salt *Serum*.

How the extremities of the Nerves.

2. As the interior extremity, or original of the System, so not rarely the exterior, or the end, from a vellication or hauling there made, begets Spasms or Convulsive motions, and transfers them on every side: that this is done ordinarily in the outward members, the prickings of the Tendons and Nerves do testifie. No less are Spasms wont to be excited every way about, from a vellication or pulling made in the *Viscera*, when at any time Medicines, or sharp humors, also Worms lying in the Ventricle or Intestines, pull the membraneous part, and so impress a troublesome sense on the chief sensories; presently from thence, by reason of the firing of the spirits, *Convulsive motions* torment now the affected parts, and now indifferently any other parts; for oftentimes Spasms, from the more grievous hurt of some inwards, do not only imploy the affected parts, and their neighbours, but also the Muscles of the Face and Mouth, and are likewise transfer'd to the exterior members. The stone impacted in the Uriters, causes not only cruel contractions in that passage, but in all its neighbourhood. Moreover, some Hysterick and other Hypochondriack symptoms, are sometimes induced by this means; forasmuch as by a vellication made in the Membranes of some *Viscera*, thence the Spasm is returned back.

How the middle processes and foldings.

3. The irritative matter, which is wont to be the evident cause of Spasms, sometimes occupies the middle processes of the Nerves, and therefore the parts, sometimes above, sometimes beneath its seat, are incited to Convulsive motions: This appears plain enough in the foldings of the Nerves; for when the sharp recrements of the Nervous juice, are laid up in them, they do not rarely create Spasms, through the whole neighbourhood: by this means the Collick or Histerick Distemper, is often seen to be begot or excited, there being no fault in those inwards, only from the humors deposited in the foldings of the mesenterie, as we will shew hereafter, when we come to treat of those particular Distempers. In like manner, by reason that the ganglioform foldings being stopped up with a sharp and irritative humor, perfocation or choaking in the Throat, and various contractions of the *Præcordia* are caused. Besides, Spasmodick Distempers do not seldom depend upon a sharp humor within the whole trunks of the Nerves, and filling the passages of the Nervous Bodies. We have seen some troubled with admirable and perpetual Convulsions, so that they have been forced (as we have already mentioned) to run about, to leap, to fling about, and distort their members, to strike the ground with their feet and hands, and to exercise other strange gestures, even as if they had been bewitch'd; the genuine cause of which kind of passion, seems to consist in this, that the juice watering the Nervous stock, being most sharp, like stygian water, and being become degenerate from its due *Crasis*, doth irritate continually, and as it were possess with a certain madness, the spirits therein flowing and implanted.

The differences of Spasms in respect of their origine.

From these things which we have discoursed about the various causes of Convulsions, their manifold *Species* and differences are made manifest. For first, we have made known, that Spasmodick Passions are most often derived in respect of their *origine*; for the head, being affected; or the Morbific matter flowing into the beginnings of the Nerves: yet sometimes, though more rarely, they depend upon such a matter creeping into the extremities of the Nerves.

Of their causes.

2. As to the production of the Disease and Symptoms, we observe the same sometimes to be produced from a solitary evident cause, as a sudden and vehement Passion: but indeed more often to require a more remote, or procatartick cause, or previous disposition: moreover, the causes sometimes so to interfere, that the procatartick also may supply the place of the evident cause; and also on the contrary, that this may serve in the place of the other.

3. As to the extenſion of the Diſeaſe, the Convulſive Diſtemper may be diſtinguiſhed into *Univerſal*, becauſe the ſpirits actuating the whole nervous Syſtem almoſt, and the *Encephalon* it ſelf, are ſucceſſively exploded; and *particular*, in which the ſpirits within ſome private region of the animal Kingdom are diſturbed.

Of the extent of the Diſeaſe. 1. The former is meant when the animal ſpirits are irritated within their firſt fountains, to wit, the pith of the brain and cerebel, from whence their violent exploſions happen; wherefore every internal function of the Soul, to wit, the ſenſe and imagination, is obſcured, and its exterior locomotive faculty perverted: This kind of univerſal Spaſmodic Diſtemper, in which, beſides the Spaſms of the Limbs and *Viſcera*, the interior powers of the Soul ſuffer an Eclipſe, is again twofold, to wit, either primarie, which begins at the Head, and ariſes; foraſmuch as the ſpirits inhabiting that place, being imbued with nitro-ſulphureous Particles, are firſt exploded, and there inkindling, ſnatches or takes hold of the reſt, flowing in both the medulary and nervous *appendix*, and there ſtirs up Convulſive exploſions, as may be diſcerned in the Epilepſie.

2. Or this univerſal Paſſion, cauſing inſenſibility, is ſecondary, to wit, which being begun ſomewhere in the nervous ſtock; from thence plenty of ſpirits being ſucceſſively affected, becoming like the undulation or moving of waters, is at length carried to the head it ſelf: this often happens in Paroxiſms called Hyſterical, in which, by reaſon of the Spaſm begun at firſt in the bottom of the belly, or ſome intumeſcency or riſing up in the *Abdomen*, then the ſame ſpreading higher, with the ſame effect, through the pipes of the Nerves, the Ventricle, and by and by the *Præcordia*, are drawn together, and at length the Spaſm forceably ruſhing to the Head, the Patients fall down, and all Knowledg is taken from them; and laſtly, the Diſeaſe being reflected into other Nerves, Convulſive motions of the exterior members ſucceed.

2. But as to the particular Spaſm, in whoſe fit the ſick continue well in mind, this indeed is diſtinguiſhed into various differences. As to the ſeat of the matter, which happens about the beginnings, extremties, or middle proceſſes of the Nerves (as we have ſhewn) there ariſes a difference: For even as this Morbifick matter, beſieging the beginnings of the Nerves, is fixed about the head, middle, or end of the oblong pith, it therefore happeneth that ſometimes only the parts of the face, or mouth, ſometimes the *Viſcera* of the lower or middle belly; and again, ſometimes chiefly the outward limbs are hauled together.

Of the duration of the Fit. Further, a Convulſion, as to the duration of the fit, and its magnitude, uſes to be diſtinguiſhed into a continual and intermitting: The former, as we have already hinted, is called *Tenaſmus*, or a permanent contraction; as when one part, or more, being contracted or diſtorted with a conſtant ſtretching, are detained for ſome time in the ſame preternatural poſture; ſo when the Muſcles, or a Member, ſuppoſe the Eye, Lips, Cheeks, are diſtorted from their right poſition, nor cannot eaſily be preſently reduced: the cauſe of which is ſometimes a reſolution, or Palſie in ſome other Muſcles, which when they are looſened, the oppoſite do too ſtrongly act, and draw forcibly the whole part towards themſelves, which ought to ſtand as it were betwixt them, in an equal ballance: but ſometimes ſuch a permanent contraction is excited, by reaſon of the Tendons being ſtopped with an impacted ſerous humor which become for that cauſe ſtiff: this kind of Diſtemper becomes very familiar in the Scurvey, that the ſick ſometimes are not able to extend any Member or Joynt, but they are contracted round like a Globe. Sometimes the Tendons in the back, by reaſon of ſuch a courſe of humor, draw the bones out of their due ſituation, and cauſe a gibbouſneſs, or bending out of the Body. The *Tenaſme* is wont to be diſtinguiſhed into univerſal; of which there are three kinds, to wit, *Tenſion* forward, *Tenſion* backwards, and *Tenaſmus* properly ſo called; and peculiar or particular, which chiefly reſpects ſome certain Member or joynt: we will ſpeak of theſe diſtinctly hereafter.

2. The intermitting Convulſion is either ſhort and momentary, which is acted by frequent turns, and as it were by little leaps, as is to be obſerved in the quaking and ſhaking of the Tendons in horror, which are to be diſtinguiſhed between with a frequent alternation of motion and reſt: or the leapings of the Spaſms, and their intervals, are drawn out longer: ſo it is uſual for Convulſive Paroxiſms, when they are repeated, to endure for ſome time, and to leave off again; but ſuch periods are now certain, or come to certain ſet hours, now rare and incertain, and happen after a divers manner, and as various occaſions are given. There are other differences of this Diſtemper, which will be better illuſtrated hereafter, when we ſhall ſpeak particularly of each kind of Convulſions.

CHAP.

CHAPTER II.

Of the Epilepſie.

THus far we have treated of the nature, cauſes, and differences of Spaſms or Convulſions in general, according to a clean, new, and unuſual *Hypotheſis*; but (as I think) agreeable enough with Reaſon: our next buſineſs is, to explain particularly the chief kinds of that Diſtemper; amongſt which the *Epilepſie* eaſily deſerves the preheminence, and the conſideration of it ought to proceed by a certain right of method and order; for that this Diſeaſe having as it were got a large Empire in the human body, exerciſes its Tyranny not only in the whole *Encephalon*, but for the moſt part in all the parts of the Nervous Syſtem at once: wherefore by the Ancients it was called *Morbus Herculeus*, or the *Herculean Diſeaſe*, from the cruelty of the Diſtemper, and from the manner of the violent fits, as if ſent as it were by ſome Divinity, being ſo amazing; *Morbus Sacer*, or the Holy Diſeaſe; to which may be added, the conjecture of a certain Divine of our own Country, of no ſmall note, *to wit*, that many who were taken to be *Dæmonaicks*, or poſſeſſed with the Devil in the *New Teſtament*, were only Epilepticks; and that they called the cure of this Diſeaſe by our Saviour Jeſus Chriſt, an ejection or exorciſm of the evil ſpirit: In truth, in this Diſtemper, no marks at all of the Morbifick matter appears, or are ſo very obſcure, that we may have deſervedly ſuſpected it to be an inſpiration of an evil ſpirit; at leaſt it is probably, that as often as the Devil is permitted to afflict miſerable Mortals with his deluſions, he is not able to draw more cruel Arrows from any other Quiver, or to ſhew Miracles by any better Witch than by the aſſaults of this monſtrous Diſeaſe.

As the ſymptoms of the *Epilepſie* are very ſtupendious, ſo their cauſes, and the formal reaſon of the Diſeaſe it ſelf, are moſt difficult to be unfolded. For indeed, the buſineſs is variouſly controverted among Authors, both concerning the part affected, and alſo the manner of its being affected: many place its ſeat in the Brain, or its Ventricles; others in the meninges, or thin skins enwrapping the brain; and ſome again in the middle, or loweſt belly; but by what right ſhall be inquired into anon: In the mean time, laying aſide the Opinions of others, that the true ſpeculation of this Diſeaſe may be found out by the clew of right reaſoning, we will firſt of all endeavour to give you its deſcription, together with the whole ſenſe of its *Phænomenas*. Secondly, theſe things being rightly weighed, to find out the ſubject of the Diſeaſe, and its chiefly affected parts. Thirdly and laſtly, To add the means and manner whereby this Diſeaſe is begotten, with the true cauſes of its ſymptoms.

The deſcription of the Epilepſie, or the hiſtory of the Diſeaſe.

In the firſt place, As to the Idea of the Diſeaſe, the Epileptick fit or aſſault ſeems to be only an univerſal and more cruel Convulſion, to wit, in which the ſpirits inhabiting the Brain, being firſt irregularly moved, and as it were confuſed, all the reſt dwelling in both the medulary and nervous appendix of the *Encephalon*, begin at once Convulſive motions, or inordinate contractions, and continue them for ſome ſpace, with frequent leapings or palpitations: The acceſſion of the Diſeaſe comes upon them at unawares, and oppreſſes the ſick, not the leaſt thinking of it; and in the twink of an Eye caſts them on the ground, deprived of ſenſe and underſtanding; for that they do not only fall, but are flung down with a certain force, ſo that oft-times the part firſt ſtriken againſt the Earth, or other adjacent bodies, is hurt with a bruiſe or wound; being laſt done, there comes upon them a gnaſhing of Teeth, with a foam at the Mouth alſo, oftentimes the ſhaking of the Head, and a frequent knocking it againſt the ground, the Arms and Thighs, yea, the hinder part of the Neck and Back either become preſently ſlit, or elſe they are diſtorted hither and thither, with various bendings; ſome cruelly beat their Breaſts; others ſtrongly thruſt out their Arms and Thighs, and fling them, and ſometimes the whole Body, impetuouſly here and there; many have their *Præcordia* and *Hypochondria*, and alſo all their lower Belly ſwelled and blown up very much: after ſome time, ſometimes ſhorter, ſometimes longer, theſe ſymptoms, the Tragedy being as it were acted, ceaſe on a ſudden, and then the ſick come to themſelves, and recover their ſenſes: but after the fit there remains an aking in the Head, with a dulneſs and hebitude of the ſenſes, and not ſeldom a turning or giddineſs.

The *Epileptick Paroxiſms* are wont to return ſometimes at ſet times of the day, month, or year; and moſt commonly at the greater returns of the Year or Tropicks, or at the oppoſite aſpects, or conjunctions of the Sun, or Moon, they are wont more certainly to return, and to afflict more grievouſly: ſometimes their comings or acceſſions are uncertain, and wandring according to the occaſion and variety of evident cauſes: there are alſo Fits or Paroxiſms, now more light, which quickly paſs away, ſo that the ſick are ſcarce thrown to the ground, nor are carried into diſorder or inſenſibility; now more grievous, whereby they when taken lie ſenſleſs the ſpace of an hour or more, and are tormented with horrid ſymptoms, as if poſſeſſed with the Devil: Sometimes tho more rarely, ſome foregoing ſigns of the Fit, warn them of their falling into it; as an heavineſs of the Head, a brightneſs of the Eyes, a tingling of the Ears: ſometimes a Spaſm or Cramp proceeds in ſome exterior part, as in the Arm, or Thigh, or elſe in the Back, or *Hypochondria*, which aſcending from thence like a cold Air, and creeping towards the Head, ſeems to bring on their falling down. Boys and young Men are found to be more obnoxious to this Diſeaſe than old Men, or Men of mature age: who ever are once ſtruck down by its fit, unleſs they be cured by the help of Medicines, they will hardly be altogether free from the infection of it all their Life after; the more often the Fits are, the more grievous they become; which as they frequently return, become more cruel, and enervate the uſe of the memory, imagination, and reaſon, and then the ſtrength and force of the whole animal function, until its Oeconomy being greatly perverted, the vital function at length decays, and by degrees is aboliſhed. The weapons and wicked preparation of this Diſeaſe, being after this manner laid open, we will next make an inquiry in what part it fixes its ſeat, or what is its next ſubject.

The ſubject or the ſeat of the Diſeaſe is inquired into.

The acceſſion of the Epilepſie, and the manner of invaſion, ſeem plainly to declare, that its primary ſeat, or part chiefly affected, is contained ſomewhere within the Head; but that a Paroxiſm ſometimes begins in the remote parts, and from thence aſcends towards the Head, which indeed ſeems only to be ſo, and happens by accident, when in the mean time the Morbifick cauſe ſubſiſts about the *Encephalon* it ſelf, (as ſhall be anon declared:) but that from the firſt aſſault of the Diſeaſe, preſently a ſtrange inſenſibility and diſorder, with contractions almoſt of all the Members and *Viſcera* ſucceeds, it is a manifeſt ſign that the whole joynting of the *Encephalon*, and the original of all the Nerves, are poſſeſſed with the Morbific cauſe: But truly, although it ſeem moſt difficult to unfold where this cauſe or morbifick matter ſubſiſts chiefly; for, neither is it probable that the ſame is diffuſed thorow all the parts of the Brain, yet it neither appears in what ſingular place this being fixed ſhould draw all the other parts ſo ſuddenly into a conſent of its evil.

Some affirm it the meninges or thin skins of the Brain; other the pith or middle part of the Brain.

Among the various opinions of Authors about this matter, there are two that ſeem more probable than the reſt, and challenge an aſſent with an equal likelineſs to Truth. One of which aſſerts the very middle of the brain; and the other the meninges, or the thin skins encompaſſing or cloathing it, to be the primary ſeat of the Epilepſie: The reaſon of the former is founded in this, that where the fountain of the animal ſpirits, and the original of the ſenſitive ſoul it ſelf conſiſts, there ought to be placed the cauſe of this Diſeaſe; certainly when the chief faculties are firſt hurt, all the reſt eaſily participate of the ſame evil: But in truth, though I may grant in the Apoplexy, and the *deliquium* or fainting of the ſpirits, that it is ſo, yet it follows not in a Convulſion (of which kind of Diſtemper the *Epilepſie* is) that all the *Fibres* and Nerves ſhould be pulled together, becauſe the middle part of the brain is firſt pulled: for that this, as it is a moiſt and fluid ſubſtance, and wanting of ſenſe and motion, ſeems not capable of contraction, or the Spaſmodic Diſtemper: wherefore others thinking the brain and every part of it, free from the blame of this Diſeaſe, caſt it altogether on the meninges: affirming, that the membranes, cloathing the brain, and chiefly their proceſſes, ſpread upon the clefts of the brain, and *Cerebel*, as they are hauled by the morbifick matter, do conceive or beget Spaſms or horrid Convulſions, and then that from the Meninges themſelves ſo contracted and brought together, the included brain is greatly compreſſed and bound together, ſo that its pores and paſſages being bound up, the great amazing diſorder and inſenſibility is induced, and alſo the trunks of the Nerves, to which either meninge or skin is faſtened, being brought into a conſent with them, enter alſo into Convulſive motions: And indeed after this manner the formal reaſon of the Epilepſie may perhaps ſeem to be unfolded; but truly when I conſider further of the matter, I think we may differ from this opinion, becauſe it does not appear by what courſe, or for what cauſe, the falling down being at hand, theſe meninges ſhould beget ſuch horrid Spaſms. Nay, it neither appears, how from them, however Convulſive they be, the Epileptick Paroxiſm ſhould be induced.

As

As to the former, it ſeems an impoſſible thing, for the meninges to be ſo contracted, as to their whole Concavities, that being bound more ſtrictly together, like a purſe, they ſhould on every ſide pull together their contents, and draw them into a narrower ſpace: for that the *Dura Mater* ſticks moſt firmly to very many places of the skull, yea, and the *Pia Mater* is tied to it, near the proceſſes of the hollow turnings, by a mutual knitting of the membranes, and every where beſides with a continuity of Veſſels: hence it eaſily appears, either that membrane, as to the greateſt part of it, is immovable, ſo that they cannot fall into ſo univerſal Spaſms: but in reſpect of leſſer Spaſms, as when a certain portion of this or that meninge, or both together, is pulled, indeed we grant ſuch may happen: for I have often heard thoſe troubled with great headach to complain extreamly of a great conſtriction of the parts, lying under the ſide of the skull; ſometimes on the right, ſometimes on the left, and yet from thence no aſſault of falling down has followed: Further as thoſe membranes being notably hurt, do cauſe great vellications or haulings, yet upon it there is not wont to be an Epileptick fit to follow: for I have known, from an Impoſthume in the *Dura Mater*, when being broken and that the ſtinking matter had knawn the more tender meninges, and ſhell of the Brain, that the ſick hath fallen into an amazedneſs, and at length into a deadly Apoplexy, who notwithſtanding in the whole courſe of the Diſeaſe, was free from any Epileptical Symptom. Alſo I remember, I have ſeen one, who had the *Dura Mater* very much torn by the Inſtrument of an unskilful Surgion, and another that by a wound, had that with part of his skull taken away, ſo that a portion of the brain ſwelled forth, and yet to neither of them any Epilectical paſſion hapned; wherefore neither is it likely that the blood or humours, or (if any ſhall ſo argue) the vapours, compacted within thoſe meninges, can bring in any greater evil than either a ſtroke or wound inflicted on them, or filthy matter there poured out: Beſides, thoſe who are more lightly troubled with the *Epilepſie*, ſo that they ſcarce fall down, and have their minds free through the whole aſſault of the diſeaſe, would perceive the membranes to be ſo contracted, and the globe of the brain to be more ſtraitly thruſt together, if there had bin any ſuch kind of affection; but they on the contrary ſeem to have the brain as it were inflamed, and to be ſenſible, that the ſpirits leap forth, and are as it were exploſed, with a certain fierceneſs.

It is affirmed, that the meninges are not firſt of all affected.

The ſpirits inhabiting the middle of the brain are the primary Subject of the diſeaſe.

As indeed, I think it is very likely ſo, that the Epileptick Paroxiſm is ſtirred up from a certain ſudden rarefication, and exploſion of the animal ſpirits, inhabiting the brain, which are in truth the firſt and immediate ſubject of this Diſeaſe; to wit, whereby the Brain it ſelf is inflated, and rendred ſo inſenſible, and the nerves hanging thereto, alſo put into Convulſions: For hence it comes to paſs that the acceſſion of this Diſeaſe begins ſo on a ſudden, and determines perfectly without any great proviſion or remains of the morbifick matter; becauſe the Infection is not brought ſo much to the ſolid parts, as to the ſpirits themſelves.

We have already ſhown by what means, the heterogeneous and exploſive *Copula*, conſiſting as it ſems of *nitro ſulphureous* particles, cleaving to the ſpirituous particles of the animal Spirits, and laſtly, being ſmitten and exploſed by them by reaſon of plenitude or irritation produces Convulſive Symptoms: But altho this kind of Spaſmodick *Copula*, is firſt diſtilled from the blood into the brain, yet for the moſt part it does not take hold of the ſpirits there, or at leaſt it ſtays not long with them in that place: but rather being thruſt from thence towards the nervous *Appendix*, cauſes particular and reſpective Spaſms, near the places affected: But ſometimes if the ſpaſmodick matter be more plentiful and ſtrong, and the conſtitution of the brain weak, the heterogeneous *Copula*, being fixed to the Spirits, not only in the nervous ſtock, but alſo to thoſe planted within the *Encephalon* it ſelf cauſes the epilectick diſpoſition; and the exploſive particles of the Spirits, and this *Copula* knocking one againſt another, ſtir up the falling fit. For indeed, ſince the aſſault of the *Epilepſie* urging the inſenſibility, and great diſorder, is for the moſt part the firſt Symptom, and all the pathognomick, it may be concluded that the Animal Spirits lying within the middle of the Brain it ſelf, are affected before others; and that therefore that part is the principal ſeat of the diſeaſe: Then, foraſmuch as the falling of the ſick, or caſting to the ground, and ſpaſms of the members and *Viſcera* moſt often follow that Inſenſibility great diſorder, or leaping forth of the ſpirits, it follows that the animal Spirits alſo inhabiting the Nervous Syſtem, are imbrued with the ſame exploſive *Copula*, and are drawn into conſent with thoſe inhabiting the brain it ſelf, and are excited by them, to exploſions purely inordinate; altho ſometimes (by the whole *ſeries* of Spirits, planted both in the brain and nervous ſtock, being like a long train of gunpowder, prediſpoſed to exploſions) an exterior Spaſm, beginning a great way off, perhaps in ſome member or inward, may afterwards be carried to the Brain, as ſhall be more fully ſhown hereafter. In the mean time, it is concluded, that the region of the Brain it ſelf is always the primary ſeat of this

The *Epileptick Paroxiſms* are wont to return ſometimes at ſet times of the day, month, or year; and moſt commonly at the greater returns of the Year or Tropicks, or at the oppoſite aſpects, or conjunctions of the Sun, or Moon, they are wont more certainly to return, and to afflict more grievouſly: ſometimes their comings or acceſſions are uncertain, and wandring according to the occaſion and variety of evident cauſes: there are alſo Fits or Paroxiſms, now more light, which quickly paſs away, ſo that the ſick are ſcarce thrown to the ground, nor are carried into diſorder or inſenſibility; now more grievous, whereby they when taken lie ſenſleſs the ſpace of an hour or more, and are tormented with horrid ſymptoms, as if poſſeſſed with the Devil: Sometimes tho more rarely, ſome foregoing ſigns of the Fit, warn them of their falling into it; as an heavineſs of the Head, a brightneſs of the Eyes, a tingling of the Ears: ſometimes a Spaſm or Cramp proceeds in ſome exterior part, as in the Arm, or Thigh, or elſe in the Back, or *Hypochondria*, which aſcending from thence like a cold Air, and creeping towards the Head, ſeems to bring on their falling down. Boys and young Men are found to be more obnoxious to this Diſeaſe than old Men, or Men of mature age: who ever are once ſtruck down by its fit, unleſs they be cured by the help of Medicines, they will hardly be altogether free from the infection of it all their Life after; the more often the Fits are, the more grievous they become; which as they frequently return, become more cruel, and enervate the uſe of the memory, imagination, and reaſon, and then the ſtrength and force of the whole animal function, until its Oeconomy being greatly perverted, the vital function at length decays, and by degrees is aboliſhed. The weapons and wicked preparation of this Diſeaſe, being after this manner laid open, we will next make an inquiry in what part it fixes its ſeat, or what is its next ſubject.

The ſubject or the ſeat of the Diſeaſe is inquired into.

The acceſſion of the Epilepſie, and the manner of invaſion, ſeem plainly to declare, that its primary ſeat, or part chiefly affected, is contained ſomewhere within the Head; but that a Paroxiſm ſometimes begins in the remote parts, and from thence aſcends towards the Head, which indeed ſeems only to be ſo, and happens by accident, when in the mean time the Morbifick cauſe ſubſiſts about the *Encephalon* it ſelf, (as ſhall be anon declared:) but that from the firſt aſſault of the Diſeaſe, preſently a ſtrange inſenſibility and diſorder, with contractions almoſt of all the Members and *Viſcera* ſucceeds, it is a manifeſt ſign that the whole joynting of the *Encephalon*, and the original of all the Nerves, are poſſeſſed with the Morbific cauſe: But truly, although it ſeem moſt difficult to unfold where this cauſe or morbifick matter ſubſiſts chiefly; for, neither is it probable that the ſame is diffuſed thorow all the parts of the Brain, yet it neither appears in what ſingular place this being fixed ſhould draw all the other parts ſo ſuddenly into a conſent of its evil.

Some affirm it the meninges or thin skins of the Brain; other the pith or middle part of the Brain.

Among the various opinions of Authors about this matter, there are two that ſeem more probable than the reſt, and challenge an aſſent with an equal likelineſs to Truth. One of which aſſerts the very middle of the brain; and the other the meninges, or the thin skins encompaſſing or cloathing it, to be the primary ſeat of the Epilepſie: The reaſon of the former is founded in this, that where the fountain of the animal ſpirits, and the original of the ſenſitive ſoul it ſelf conſiſts, there ought to be placed the cauſe of this Diſeaſe; certainly when the chief faculties are firſt hurt, all the reſt eaſily participate of the ſame evil: But in truth, though I may grant in the Apoplexy, and the *deliquium* or fainting of the ſpirits, that it is ſo, yet it follows not in a Convulſion (of which kind of Diſtemper the *Epilepſie* is) that all the *Fibres* and Nerves ſhould be pulled together, becauſe the middle part of the brain is firſt pulled: for that this, as it is a moiſt and fluid ſubſtance, and wanting of ſenſe and motion, ſeems not capable of contraction, or the Spaſmodic Diſtemper: wherefore others thinking the brain and every part of it, free from the blame of this Diſeaſe, caſt it altogether on the meninges: affirming, that the membranes, cloathing the brain, and chiefly their proceſſes, ſpread upon the clefts of the brain, and *Ceribel*, as they are hauled by the morbifick matter, do conceive or beget Spaſms or horrid Convulſions, and then that from the Meninges themſelves ſo contracted and brought together, the included brain is greatly compreſſed and bound together, ſo that its pores and paſſages being bound up, the great amazing diſorder and inſenſibility is induced, and alſo the trunks of the Nerves, to which either meninge or skin is faſtened, being brought into a conſent with them, enter alſo into Convulſive motions: And indeed after this manner the formal reaſon of the Epilepſie may perhaps ſeem to be unfolded; but truly when I conſider further of the matter, I think we may differ from this opinion, becauſe it does not appear by what courſe, or for what cauſe, the falling down being at hand, theſe meninges ſhould beget ſuch horrid Spaſms. Nay, it neither appears, how from them, however Convulſive they be, the Epileptick Paroxiſm ſhould be induced.

As

As to the former, it ſeems an impoſſible thing, for the meninges to be ſo contracted, as to their whole Concavities, that being bound more ſtrictly together, like a purſe, they ſhould on every ſide pull together their contents, and draw them into a narrower ſpace: for that the *Dura Mater* ſticks moſt firmly to very many places of the skull, yea, and the *Pia Mater* is tied to it, near the proceſſes of the hollow turnings, by a mutual knitting of the membranes, and every where beſides with a continuity of Veſſels: hence it eaſily appears, either that membrane, as to the greateſt part of it, is immovable, ſo that they cannot fall into ſo univerſal Spaſms: but in reſpect of leſſer Spaſms, as when a certain portion of this or that meninge, or both together, is pulled, indeed we grant ſuch may happen: for I have often heard thoſe troubled with great headach to complain extreamly of a great conſtriction of the parts, lying under the ſide of the skull; ſometimes on the right, ſometimes on the left, and yet from thence no aſſault of falling down has followed: Further as thoſe membranes being notably hurt, do cauſe great vellications or haulings, yet upon it there is not wont to be an Epileptick fit to follow; for I have known, from an Impoſthume in the *Dura Mater*, when being broken and that the ſtinking matter had knawn the more tender meninges, and ſhell of the Brain, that the ſick hath fallen into an amazedneſs, and at length into a deadly Apoplexy, who notwithſtanding in the whole courſe of the Diſeaſe, was free from any Epileptical Symptom. Alſo I remember, I have ſeen one, who had the *Dura Mater* very much torn by the Inſtrument of an unskilful Surgion, and another that by a wound, had that with part of his skull taken away, ſo that a portion of the brain ſwelled forth, and yet to neither of them any Epilectical paſſion hapned; wherefore neither is it likely that the blood or humours, or (if any ſhall ſo argue) the vapours, compacted within thoſe meninges, can bring in any greater evil than either a ſtroke or wound inflicted on them, or filthy matter there poured out: Beſides, thoſe who are more lightly troubled with the *Epilepſie*, ſo that they ſcarce fall down, and have their minds free through the whole aſſault of the diſeaſe, would perceive the membranes to be ſo contracted, and the globe of the brain to be more ſtraitly thruſt together, if there had bin any ſuch kind of affection; but they on the contrary ſeem to have the brain as it were inflamed, and to be ſenſible, that the ſpirits leap forth, and are as it were exploſed, with a certain fierceneſs.

It is affirmed, that the meninges are not firſt of all affected.

The ſpirits inhabiting the middle of the brain are the primary Subject of the diſeaſe.

As indeed, I think it is very likely ſo, that the Epileptick Paroxiſm is ſtirred up from a certain ſudden rarefication, and exploſion of the animal ſpirits, inhabiting the brain, which are in truth the firſt and immediate ſubject of this Diſeaſe; to wit, whereby the Brain it ſelf is inflated, and rendred ſo inſenſible, and the nerves hanging thereto, alſo put into Convulſions: For hence it comes to paſs that the acceſſion of this Diſeaſe begins ſo on a ſudden, and determines perfectly without any great proviſion or remains of the morbifick matter; becauſe the Infection is not brought ſo much to the ſolid parts, as to the ſpirits themſelves.

We have already ſhown by what means, the heterogeneous and exploſive *Copula*, conſiſting as it ſems of *nitro ſulphureous* particles, cleaving to the ſpirituous particles of the animal Spirits, and laſtly, being ſmitten and exploſed by them by reaſon of plenitude or irritation produces Convulſive Symptoms: But altho this kind of Spaſmodick *Copula*, is firſt diſtilled from the blood into the brain, yet for the moſt part it does not take hold of the ſpirits there, or at leaſt it ſtays not long with them in that place: but rather being thruſt from thence towards the nervous *Appendix*, cauſes particular and reſpective Spaſms, near the places affected: But ſometimes if the ſpaſmodick matter be more plentiful and ſtrong, and the conſtitution of the brain weak, the heterogeneous *Copula*, being fixed to the Spirits, not only in the nervous ſtock, but alſo to thoſe planted within the *Encephalon* it ſelf cauſes the epilectick diſpoſition; and the exploſive particles of the Spirits, and this *Copula* knocking one againſt another, ſtir up the falling fit. For indeed, ſince the aſſault of the *Epilepſie* urging the inſenſibility, and great diſorder, is for the moſt part the firſt Symptom, and all the pathognomick, it may be concluded that the Animal Spirits lying within the middle of the Brain it ſelf, are affected before others; and that therefore that part is the principal ſeat of the diſeaſe: Then, foraſmuch as the falling of the ſick, or caſting to the ground, and ſpaſms of the members and *Viſcera* moſt often follow that Inſenſibility great diſorder, or leaping forth of the ſpirits, it follows that the animal Spirits alſo inhabiting the Nervous Syſtem, are imbrued with the ſame exploſive *Copula*, and are drawn into conſent with thoſe inhabiting the brain it ſelf, and are excited by them, to exploſions purely inordinate; altho ſometimes (by the whole *ſeries* of Spirits, planted both in the brain and nervous ſtock, being like a long train of gunpowder, prediſpoſed to exploſions) an exterior Spaſm, beginning a great way off, perhaps in ſome member or inward, may afterwards be carried to the Brain, as ſhall be more fully ſhown hereafter. In the mean time, it is concluded, that the region of the Brain it ſelf is always the primary ſeat of this

this diſeaſe; and that we ought to ſuppoſe the conjunct cauſe of the diſtemper, not to be water heaped up within the ventricles of the brain, nor a thick or clammy humour impacted in the paſſages of its pores: for ſuch cauſes are begotten by degrees, and therefore would ſhew ſome certain ſigns before hand, of the firſt coming upon one: further, the aſſault of the fit being over, ſuch a matter could not be wholly diſcuſſed in ſo ſhort a time, but that from its reliques ſome impediments of the animal function would remain, which indeed rarely happens in the Epilepſie unleſs inveterate: but, for the exciting of the falling down, no leſs can be imagined, than that the animal Spirits which flowing within the marrowie ſubſtance of the brain, perform the acts of the interior ſenſe of the imagination and appetite, having got an heterogeneous *Copula*, ſhould be inordinately exploded, and ſo they being diſturbed beyond their orders and ſtations, the ſuperior faculties of the animal regimen, muſt ſuffer an eclipſe; then, from this greater exploſion of Spirits as it were from a fiery enkindling, other Spirits inhabiting the marrowy and nervous appendix, being alſo prædiſpoſed to exploſions, conceive the like diſorder, and in like manner cauſe the exploſive convulſive motions of the containing bodies.

The diſeaſe affects ſecondarily very many parts of the Nervous Syſtem.

For altho we conclude, that the middle of the brain is always the primary ſeat of the Epilepſie, and that from the beginning, the morbific matter is laid up wholly in that Region; yet the diſtemper growing grievous, this being more plentifully ſpread thorow the head, enlarges its bounds, ſo that it being ſtrowed here and there, and far and near ſtretched out, Spaſmodick particles are caſt into the reſt of the Brain, and alſo into the nervous *appendix* like gunpowder or exploſive ſeed, whereby it comes to paſs, that at the firſt approach of that diſorder of ſpirits, convulſions follow ſometimes in theſe, ſometimes in thoſe parts, and not rarely thorow the whole body.

CHAPTER III.

The Differences of the Epilepſie, and the reaſons of ſome of the Symptoms are unfolded. Alſo its Curatory Method is repreſented.

THus far of the eſſence and the cauſes in general of the Epilepſie; it ſhall be now our next task to explicate the differences of this Diſeaſe, alſo the reaſons of ſome of the accidents and Symptoms belonging to it; to which we will laſtly add, Obſervations and Hiſtories of ſick people, with the method of curing.

The moſt notable difference of the Epilepſie, is wont to be taken from the Subject, to wit, that the brain or part of it, labouring with this diſeaſe, is either primarily, and idiopathetically or properly affected, or ſecondarily and not but by a conſent with other parts: concerning the former kind, we have hitherto diſcourſed as to the other, to wit, in which the falling down ſeems to ariſe from ſome place without the head, and then lays hold of it ſecondarily, and as it were by a blaſt ſent from elſewhere; it is to be obſerved, that this kind of diſtemper (as *Galen* hoth noted) proceeds either from the external or internal parts: we meet with many examples of Epilepticks, in whom the fit being juſt coming upon them, a ſpaſm is felt with a numneſs in the hand or toe, or other particular member, which preſently from thence as it were with a pricking or tingling, creeps towards the head, which when it hath attained, immediately the ſick party falls flat on the earth, and is hurried into inſenſibility and diſorder of Spirits, and other proper demonſtrations of the Symptome of the falling-ſickneſs; neither is it a leſs uſual *proœmium* of this diſeaſe, that there firſt ariſes as it were a conflict in the ſtomach, ſpleen, womb, inteſtines, genitals or other inwards: or that ſome kind of perturbation is raiſed in ſome of them; then from that place, the aſcent of (as it were) a cold air is perceived, to which diſtemper follows the acceſſion of the falling evil, with its moſt horrid proviſion of ſymptomes: hence it was commonly believed that the cauſe of the Epilepſie lay hid in the part, ſeen to be ſo primarily affected, and propagated its evil to the brain, of its ſelf innocent.

The Reaſon of the Epilepſie which is ſaid to be excited by conſent.

But in very deed, as to this we muſt ſay, that in every Epilepſie not only the procatartick or remoter Cauſe, but alſo the conjunct remains wholly in the brain: to wit, that the ſpirits inhabiting it, being diſpoſed to exploſions, and there being exploſed, bring on or cauſe

cauſe every falling evil. As to thoſe præliminary Symptoms in ſome epilectical people, they ſometimes have the place of an evident cauſe, and ſometimes only of a ſign: For when the evil diſpoſition of any inward, as the ſtomach, ſpleen or womb, happens with the diſpoſition of the Epilepſie, as often as any perturbation is begun in that diſtempered inward, it eaſily happens by reaſon of a tranſmiſſion of the ferment from thence, or a continuation of the ſpaſm to the head, an Epileptical fit is excited in the brain prædiſpoſed to act.

But theſe kind of ſymptoms of the falling evil, which being ſuſcitated from without ſeem to propagate the diſtemper to the brain, do often ariſe from the conſent of the brain it ſelf, and are only ſigns of the approach of the epileptical Fit, or of the ſpirits beginning to be exploded in the brain: For when the animal ſpirits planted in the middle parts of the brain and Cerebel, and alſo thoſe in the oblong pith or marrow, neat the beginnings of the Nerves are ſo filled with an heterogeneous *Copula*, that for the caſting it off, they are ready to bring on the aſſault of the diſeaſe, before they are all exploded heap by heap, ſome ſpirits lying more outward in ſome private Nerves, becauſe they are deſtitute of the wonted influx of their ſuperiors, fall into certain inordinations, and ſo begin ſpaſms, which ſpaſms (as it it is often the manner in this kind of diſtemper) begin at the extremities or ends of the Nerves inſerted to this or that member or inward, from whence by degrees they creep forward to their beginnings; whither being come forth with the ſpirits thorow the whole *Encephalon* before diſpoſed to exploſions, being moved by that ſpaſms, and ſo being ſnatched away with a fiery enkindling, are ſuddenly exploded or thruſt out; ſo they ſeem to ſtir up the Epileptick Fit, beginning at firſt from themſelves as it were ſecondarily and by inſtinct, brought from ſome other place: After this manner, ſometimes the Hiſterical paſſions, when beginning in the bottom of the belly, they are communicated to the brain, are thought to ariſe from thoſe Viſcera, and to be ſtirred up by their fault; when in the mean time, the morbific cauſe ſubſiſts chiefly about the beginnings of the Nerves, as we have elſewhere ſignified, and ſhall again ſhow hereafter, when we come to treat particularly of the Spaſmodick diſtempers.

Other differences of the Epilepſie.

There yet remain other differences of the falling ſickneſs, to wit, that it is either hæreditary or acquired; again, either kind is variouſly diſtinguiſhed by reaſon of the Age or time, in which it firſt comes upon one, to wit, when the firſt coming of it happens before, or about the puberty or being of ripe age or after it; further as to the Efficacy of the diſeaſe into ſtrong and weak, for as much as the Paroxiſms or Fits are with, or without the diſorder of ſpirits, and falling as to its inordinate manner, whoſe aſſaults are wandring and uncertain, moreover it is wont to be diſtinguiſhed according to the peculiar Symptoms in theſe or thoſe ſick people, by reaſon of ſome diſpoſition, or manifold Idioſyncraſy, or propriety of the Temperament.

But from what has been ſaid before of very many of the ſymptoms, which are to be met with in this diſeaſe, the cauſes do eaſily appear, ſo that there will be no need here to conſider all of them: but of ſome of them, which ſeem more intrinſecate, it will not be from the matter to diſcourſe in this place.

Why Epileptick fall down with violence.

We will therefore firſt of all inquire, why thoſe ſick of this diſeaſe, do not fall as thoſe that are apoplectick, or have ſwounding fits, but are rather ſtricken down with violence againſt the Earth or any other bodies, that are by chance oppoſite to them, as if they were ſmitten down by ſome wicked Spirit, ſo that very often ſome part of the head, or face is hurt with the violent fall: And thoſe ſo diſtempered, even like the Dæmonaicks in the Goſpel, are frequently flung into the fire, or the water; but it may be here declared, that the Epilepticks become obnoxious to theſe kind of evils, for that the fit coming upon them, all knowledg or providence is taken from them; and further, the nerves neighbouring to the head, being ſtrongly contracted, the whole bulk of the body is carried away headlong: but in the Syncope and Apoplexie, the fall of the diſtempered body, ſeems as the ruines of a building, which happens by reaſon that its Props are taken away: but indeed in the falling Sickneſs, it is no otherwiſe than if a houſe were overthrown by the blowing up of gunpowder, which is removed much from the place where it ſtood.

From whence the Foam at the mouth of theſe troubled with the falling ſickneſs comes.

Secondly, It is commonly eſteemed a great Pathognomick, or Peculiar Symptom of the Epilepſie, if when the diſeaſed being fallen to the earth, and ſuffering moſt horrid Convulſions, there flows from the mouth, a ſpumous ſpittle or foam, which indeed is thought to be preſſed from the brain, being ſtrongly contracted into the Palate: But in truth, though it be granted that this flux of ſpume be very often a ſign of the falling Sickneſs, yet it is not ſo appropriated to this diſeaſe, but that the ſame ſometimes happens in the Apoplexie, in deep ſleep, in hyſterical diſtempers, and other convulſive diſeaſes: Beſides this kind of foam, does not deſcend from the Brain, for there is no paſſage

open

open, by which it may paſs, but from the Lungs being inflated and elevated even to the Larinx, or the top of the ſharp Arterie, from whence ſpittle foams forth, with a certain fervency and ebullition: For the fit of the falling evil growing urgent, when moſt of the Nerves in the whole Body are drawn together, thoſe alſo that ſerve for the motions of the Lungs and Diaphragma, ſuffer moſt cruel Convulſions, and liſting up all the *Præcordia* upwards, continue them almoſt immovable, in a long Syſtole, ſo that the breathing, and pulſe, cannot be at all perceived; In the mean time, becauſe the blood ſtraitned within the boſom of the heart diſtends it, and alſo almoſt choaks it, the Lungs however hindred that they cannot be moved after their wonted and natural manner, perform what they can, with a thick and haſty agitation, whereby the blood may be drawn forth from the Heart; by which endeavour of theirs, the ſhaking air, by the frequent or thick reſpiration, raiſes the viſcous or clammy humidity into froth, like the ſhaking of the white of an Egg; by and by it lifts it upwards towards the cavity of the mouth, and ſo at laſt drives it out of doors: wherefore a foam or ſpumous ſpittle does often ſucceed in other Diſtempers, where the pneumonic or breathing Nerves are either contracted, or are hindred from performing their Function.

Why ſome in the falling knock their Breaſts.

Thirdly, Moreover, from the ſame reaſon it comes to paſs, that ſome Epilepticks being fallen to the ground, beat moſt grievouſly their Breaſts with their Hands, and are hardly to be held from it: for when the *Præcordia* being troubled with the Spaſm, and hindred that they cannot move themſelves after their wonted manner, and the blood ſtagnating in them, not without a great oppreſſion of the heart, threatens a ſuffocation of Life; then it is that the ſick ſtrikes their Breaſt, to wit, that the *Præcordia* ſo ſhaken, and as it were moved up and down, might renew their motions, and ſo the blood might be relieved from its ſtagnation, and the heart from its heavy oppreſſion: and this is done after the ſame manner, as when ſome that are ſleeping being tickled, or bit by a flea, unknown to themſelves, preſently rub, or ſcratch the affected place.

The prognoſtication of the Diſeaſe.

As to the Prognoſtication of the Diſeaſe, we have already declared, that it is of very difficult cure, which difficulty conſiſts in this, that the middle of the Brain (in which is the chief ſpring and fountain of the animal ſpirits) is very much debilitated, not only by the Morbifick cauſe, but alſo by its effects, to wit, the ſeveral fits; and its pores looſened, ſo that they lie open for the entrance of every Heterogeneous matter: and ſo the Morbid diſpoſition it ſelf being confirmed by the repeated Paroxiſms, and taking deeper root, it is hardly taken away. But it is to be obſerved, that the Epilepſie ſometimes terminates of it ſelf, and is ſometimes overcome by the help of Medicines: which happens about the age of puberty, and then only; ſo that who are not cured, that time being elapſed, that is before the twenty fifth year of age, they ſcarce ever after recover their health; for about the time of ripe age there is a twofold alteration of the humane Body, and therefore there often happens a ſolution or looſing of the Falling ſickneſs, or of any other Diſeaſe deeply rooted: For firſt, at that time, the genital humor begins to be heaped together in the ſpermatick Veſſels, from whence it follows, that the ſpiritious Particles, and what are wont to grow to them, nitro-ſulphureous and Morbifick Particles are laid up, not only in the brain, but alſo in the teſticles: wherefore if this Heterogeneous *Copula* of the ſpirits be more plentifully carried to that new ſtore-houſe, from thence the brain becoming free, often leaves the Epileptical or otherways Morbid diſpoſitiou. 2. About the time of ripe age, as the Blood pours forth ſomething before deſtinated for the brain through the ſpermatic Arteries to the genitals, ſo alſo it receives as a recompence, a certain ferment from thoſe parts through the Veins, to wit, certain Particles imbued with a ſeminal tincture, are carried back into the bloody maſs, which makes it vigorous, and inſpire into it a new and lively virtue; wherefore at that time the gifts both of the Body and Mind chiefly ſhew themſelves; Hairs break out, the Voice becomes greater, the Courſes of Women flow, and other accidents happen, whereby it is plain, that both the Blood and Nervous Juyce, are impregnated with a certain freſh ferment: wherefore the Morbific ferments or ſeeds, unleſs they be overcome by this new natural ferment, they afterwards continue untameable even to death.

But that the Epilepſie is ſometimes cured by the help of Medicines, experience doth teſtify: we ſhall anon Diſcourſe of the method of healing, and ſhew the reaſons of the moſt famous Medicines; in the mean time, as to what further belongs to the prognoſtication of this Diſeaſe, if it end not about the time of ripe age, neither can be driven away by the uſe of Medicines, there happens yet a divers event in ſeveral ſick Patients, for it either ends immediately in Death, or is changed into ſome other Diſeaſe, to wit, the Palſie, Stupidity, or Melancholy, for the moſt part incurable.

The Epilepſie is changed into other Diſeaſes.

As to the former, when as the fits are often repeated, and every time grow more cruel, the animal function is quickly debilitated: and from thence, by the taint, by degrees brought on the Spirits, and the Nerves ſerving, the Præcordia the vital function is by little and little enervated, till at length the whole body languiſhing, and the pulſe being looſned, and at length ceaſing, at laſt the vital flame is extinguiſhed.

But that this Diſeaſe often ends in the palſie, melancholly, or madneſs, the reaſon is, becauſe the tone, and confirmation of the brain is depraved by the often exploſions of the animal Spirits, and at length its natural ſtate is ſo perverted, that by the morbifick particles of another kind alſo admitted, the ſpirits are fixed, nor are any more exactly prone to exploſions, but rather ſometimes by a contrary vice introduced, their Elaſtick virtue is too much wanting, ſo that they become dull and ſluggiſh beyond meaſure; even, as oftentimes the intemperature of the blood, being more cold than it ſhould be, admits the more intenſe burning of a fever: and indeed, theſe depreſſions of the ſpirit happens partly by their own proper fault; for that their more agil particles being too much exploſed, the more dull or heavy, are only left, and from them they are ſupplied; but partly, as we have ſaid, they happen from the fault of the brain; for that its pores and paſſages, are ſo dilated and opened, from the often paroxiſms of this falling evil, that afterwards, there is an open paſſage made, for any heterogeneous, and divers kinds of morbifick particles, to enter with the Nervous juice.

Of the Curatory part of the Epilepſie.

Thus much for the Diagnoſis and Prognoſis, the deſcription and judgment of the Epilepſie, or falling ſickneſs; in the unfolding of which, it was neceſſary to bring reaſons not altogether abſtruſe and different from the common Pathology, neither are we conſtrained to receede in the Therapeatick or Curatory part of this Diſeaſe from the common and uſual method of curing in other diſtempers: But in truth, the preſcriptions of ſuch who follow the ordinarily received Opinions, by which, for the moſt part, they endeavour to carry away, and wholly to eradicate the morbifick matter, by Catharticks only, do little or nothing avail in the falling ſickneſs, yea they are wont frequently to be hurtful to it. I have known ſome famous Practitioners, omitting wholly the ſeries of the Curatory intentions, betake themſelves to certain Empirical Remedies, without the foreſight of the whole; this kind of practiſe, though ſometimes it ſucceeds happily, would much more certainly perform the propoſed cure, if the body being rightly prepared, they ſhould in like manner take away all Impediments, by other medicines.

Wherefore, the Indications concerning the cure of the Falling Sickneſs, ſhall be (as they are commonly ſet down) either curatory, which have reſpect to the Fit, and drive it away either coming on, or when upon them, to ſet it going the ſooner: or prophylactick or preventory, which have reſpect to the Cauſe of the Diſeaſe, which if they can take away, its acceſſions will be inhibited afterwards.

A general evactuation has ſcarce any place in the former Intention; for in the fit, neither a Vomit, or Purge, and very rarely the opening a vein, are wont to be adminiſtred; if the amazed inſenſibility and diſorder continues very long, ſometimes a Clyſter is wont to be uſed, but what that chiefly aims at is, to fix the too fierce and volatile animal Spirits, and alſo to ſuppreſs their begun exploſions: For which ends, two kind of Remedies chiefly are made uſe of; to wit, Firſt, ſuch as repreſs the animal ſpirits, being too apt to grow fierce and to leap forth, and repel them with ſome perfume that is ingrateful to them, and compel them into order: which thing indeed medicines imbued with a volatile, or armoniack ſalt, or alſo with a vitriolic ſulphur do effect, of which kind are ſalt and oyl of Amber, Spirits of Blood, Harts-horn, Sut, tincture of Caſtor, and ſuch like: for theſe being inwardly taken, or put to the noſe, oftentimes bring help, and the evil ſpirits of this Diſeaſe are thought to be driven away, even as in *Tobit*, the Devil was by the fume of the gall of a fiſh. Secondly, the animal ſpirits are called away, or hindred from their begun exploſions, when they are allured, or held buſied in ſome work they are accuſtomed to: wherefore, the fit urging, frictions being uſed, and for ſome time continued thorow the whole body do often help: but ſome that ſet upright the diſeaſed, and altogether hold or reſtrain their arms and legs, from their convulſive motion, or hold them violently in this or that poſture; that alſo blow things into their noſes to make them ſneeſe, and pour down ſtrong Cordials at the mouth, and apply either Cupping-glaſſes, and Scarrifications, and handle more ſharply with other manner of adminiſtrations thoſe ſick people, and diſturb the manner of the fit, I ſay this kind of practiſe is moſt often too roughly inſtituted or ordained: becauſe after this manner there is a double trouble put upon nature, to wit, one from the diſeaſe, and the other not lighter from the ſtanders by, and helpers, when it were much better, for the fit to be ſuffered to paſs over after its own manner, and the ſick to endure but one trouble only.

Truly the chiefeſt care of a Phyſician, and efficacy of Medicines is uſed about the prevention of this Diſeaſe, that the cauſe being taken away, or its root cut off, all the fruits might wither; Medicines requiſite to this indication, reſpect many intentions, which may yet be reduced to thoſe two chief heads; to wit, in the firſt place, that the enkindling or matter of the Diſeaſe being ſupplied immediately from the vicious blood, or nervous juice, and mediately from the Viſcera and firſt paſſages be cut off; then in the ſecond place, that the evil diſpoſition of the brain, and the ſpirits its inhabitants, which is peculiar to the Epilepſie, be taken away.

As to the firſt indication here, Vomits, Purges, and other things, both evacuating, and altering, yea Phleborotomy, and Cauteries have place; foraſmuch as by theſe means and ways the impurities both of the viſcera and humors are ſubdued or brought away, and their dyſcraſie or evil diſpoſition amended: for although theſe kind of Medicines, and Medical adminiſtrations, rarely or never cure the Epilepſie by themſelves; yet thoſe take away impediments, ſet nature upright, and incite her to encounter her enemy; alſo, they prepare the way, that ſo ſpecific Remedies might more certainly and efficaciouſly ſhew their virtues; wherefore, uſually, whilſt they take care to cure this Diſeaſe, with ſecrets and hidden myſteries, they make uſe of thoſe kind of Medicines between whiles, in the Spring, and Autumn, and other fit times.

Secondly, As to ſpecific Remedies, which indeed only, though not alwaays, are able to reach the Epilepſie and to ſubdue it; of which ſort are the *Male Pæony*, *Miſſletoe*, *Rue*, *Caſtor*, the *Claws* of an *Elk*, preparations of a dead mans *Skull*, *Amber*, *Coral*, with many others. Foraſmuch as theſe are taken without any ſenſible evacuation, or alſo perturbation following in the viſcera or humors, it is a wonder by what formal reaſon, or virtue of acting, they are wont at any time to help in this Diſeaſe.

In what the Virtue of the ſpecificks conſiſts in the Epilepſie.

Concerning this matter, intricate and obſcure enough, if there may be place for conjecture, when as we have already aſſerted the procatartick cauſe of the Epilepſie, to conſiſt in the Heterogeneous *Copula*, joyning or cleaving to the ſpirits inhabiting the Brain, and inciting them to preternatural exploſions; it follows, that thoſe things which take away, or reſiſt ſuch a cauſe, muſt be of that nature, that by ſtrengthning the brain, and binding up its pores, may exclude that *Copula*, and ſo fix, and as it were bind the ſpirits, flowing within the middle or marrow of the brain, from leaving their *Copula*, that they ſhall not be any more apt or prone to irregular exploſions; perhaps after the ſame manner, as when Gun-powder or Aurum-fulminans being pounded with Sulphur, or ſprinkled with ſpirit of Vittiol, loſes its thundering virtue. And indeed, theſe kind of properties, to wit, one or both of them may be ſuſpected, yea, in a manner detected, in moſt anti-Epileptick Remedies: For truly, *Pæony*, *Miſſletoe*, *Rue*, the *Lilie* of the *Vally*, with many others, abound in a certain manifeſt aſtriction, that 'tis likely, their Particles being taken inwardly, and ſo dilated to the brain, by the Vehicle of the blood and nervous juice, do ſo bind, and ſhut up its too looſe and open pores, that afterwards they do not lie open, for the paſſage of the Morbifick matter: Beſides, for that theſe vapourous Concerts, breathe forth as it were an Armodiack ſcent or ſcattering; therefore they are ſaid to purifie the animal ſpirits, to fix them, ond to ſtrengthen them, having put off their Heterogeneous *Copula*: This virtue purifying the ſpirits, proceeding from an Armoniac Salt, is more apparent in Remedies, which are taken from the famuly of Minerals and Animals, ſuch are the preparations of the *humane Skull*, of *Blood*, *Amber*, and *Coral*, as the other, more binding, rather exiſts, in the parts and preparations of Vegitables.

It will not be needful here, for the curing of the Epilepſie, to propoſe a compleat method of healing, with exact forms of preſcriptions, becauſe there are extant every where among Authors, general Precepts, and moſt choice Remedies; and the prudent Phyſician will eaſily accommodate, both the Indications, and that plentiful proviſion of Medicinal ſtuff, to the particular caſes of the ſick. But becauſe we have exhibited a quite new Theorie of this Diſeaſe, here alſo ought to be rendred a curatory method fitted for it: which we ſhall deſcribe by and by more fully, after we have ſhewn you ſome Caſes or Hiſtories of people ſick of the Epilepſie.

1. *Obſervation.* A fair Maid, ſprung from Parents indifferently healthful, being her ſelf very well, till about her coming to ripe age, about that time, ſhe began to complain of her head being ill: And firſt of all, ſhe felt near the fore-part of her head, by fits, a vertigo or giddineſs, whereby all things ſeemed to run round; and alſo whilſt this ſymptom continued, ſhe was wont to talk idlely, and to forget whatever ſhe had but juſt done: Theſe kind of fits at firſt paſs'd away within a quarter of an hour, and came again only once or twice in a Month, in the interval of which ſhe was well enough: Afterward, the aſſaults being made more grievous by degrees, they alſo return'd more often, and within half a Year, her Brain being daily more weakend, this giddineſs or turning round

was

was plainly changed into the Epilepſie, that the ſick being ſtruck down to the ground at every fit, was affected with Inſenſibility, and horrid convulſions, and alſo with foam at the mouth. The Domeſticks obſerved, that ſhe always fell on the ſame ſide, ſo that ſitting near the fire, if ſhe ſate in the right Corner ſhe would be flung in the midſt of the fire, but if in the left Corner, ſhe fell againſt the wall of the Chimny: once when being left alone in the houſe, ſhe fell upon the burning Coals, and ſo miſerably burnt her face, and forepart of her head, that the skull being made bare of the skin and fleſh, a deep and large eſcar was burnt into it: and afterwards the outer ſhell of it fell off a hands breadth. In the mean time the ſick Maid, ſo long as the ulcers contracted by the burning, ran with filthy matter, ſhe was free from the fits; but afterwards, they being healed up, the falling evill returned: This Diſeaſe began firſt to ſhew it ſelf about the time of Puberty; for this maid, preſently after the beginning of it, had her Courſes, and afterwards they conſtantly obſerved their ſet times, tho her diſtemper grew daily worſe: Various kinds of Medicines being adminiſtred to this ſick Creature, availed nothing, becauſe it was the cuſtome and practiſe of her and her friends, quickly to change both the Phyſician, and method of Phyſick, if any happy event did not preſently follow, and to betake themſelves very much to every Emperick, and outlandiſh Mountebank.

That in this Caſe, the Vertigineous Diſtemper, with a ſhort delirium, was the forerunner of the Epilepſie, it plainly argues, the original of this Diſeaſe being planted in the middle of the brain, to depend upon a certain inordination of the Spirits; to wit, thoſe dwelling there, at the beginning, begun to admit an heterogeneous Copula; which being more plentifully heaped up, being moved either of its own accord, or occaſionally, while it was ſhaken off, induced by reaſon of the Spirits being diſturbed, and not yet very exploſive thoſe former diſtempers; Afterwards, from the ſame cauſe by degrees growing worſe, the perturbations of the Spirits did raiſe up their manifeſt exploſions, and changed the vertigo, and *Delirium* into the Epilepſie.

But that this Maid began to be ſick, about the time of ripe age, it hence evidently follows, as the natural ferment, ſo ſometimes the præternatural, explicates it ſelf, firſt at that time; wherefore as it happens, that the menſtruous purgations do then firſt break forth, ſo the ſeeds of the falling ſickneſs, whether innate or acquired, then budded forth a little, and by degrees were ripened into fruit: when the preternatural Ferment firſt appears, ofttimes the natural following blots it out, hence the Epilepſie of young ones, often ends about the time of puberty or ripe age, but if that ferment or taint of the diſeaſe, comes after the menſtruous flux, or together with it, and ceaſes not preſently, it remains for the moſt part afterwards, during life, of it ſelf untameable, and not to be overcome by any Remedies.

From this Obſervation, that a Cautery accidentally, and by chance, being made on this ſick party, freed her from the fits of the Diſeaſe, it may be inferred that fontanells or iſſues, may be profitably adminiſtred, in the cure of the Epilepſie: for whereſoever an emiſſary is opened for the conſtant carrying away of the ſerous water, both from the blood and nervous juice, there very many heterogeneous and morbifick particles flow out with it, that therefore the brain might remain free.

The Daughter of a Brewer of *Oxford*, had been very obnoxious to a Rheume falling into her eyes from her Infancy, otherwiſe ſtrong and ſound enough, alſo accuſtomed daily to hard labour, about the 14. year of her age, ſhe began to be tormented with Epileptick fits, of which ſhe ſuffered near the greater changes of the Moon, eſpecially then returning: Being asked to endeavour her Cure, I gave her a Vomit of precipitate Solar, and ordered it to be renewed three days before every new and full Moon; beſides that ſhe ſhould take at every turn for four days after the Vomit, twice in a day, a dram of male-Pæonie root in powder with a draught of black Cherry water. By theſe remedies, the fits ſo long intermitted, that the diſeaſe ſeemed to be cured. Afterwards when they returned again, ſhe was again recoveted by the uſe of thoſe medicines: and then the menſtruous flux breaking forth, and obſerving its true periods, ſhe remained for the future free from that diſeaſe. 2. *Obſervation.*

The Therapeutic or Curatory Method.

IN the Curing of the Epilepſie, I judg it fit to begin with a Cathartick, and if the ſick can eaſily bear vomiting, firſt let an Emetick be adminiſtred, and for ſeveral months let it be repeated, four days before the full of the Moon. For infants and youths, may be preſcribed wine of Squils, mixed with freſh *Oyl of Sweet Almonds*, or alſo of *Salt of Vitriol*, from half a Scruple, to 1. Scruple: For thoſe of riper years, and of a

Vomitaries. ſtronger Conſtitution may be preſcribed the following forms of Medicines. Take of *Crocus mettalorum*, or of *Mercurius vitæ* gr. iiii. to vi. of *Mercurius Dulcis* grain xvi. ℈ i. let them be bruiſed together in a mortar, mix it with the pap of a roſted Apple or of *Conſerve of Burage* one Ounce, make a Bolus; or you may take an infuſion of *Crocus Mettalorum* or *Mercurius Vitæ* made in Spaniſh Wine from half an Ounce to an Ounce and a half, or take of *Emetick Tartar* of *Mynſicht* gr. iv. to vi. who are of a tenderer Conſtitution, let them take of the *Salt of Vitrial* ℈ i. to ʒ ß, and half an hour after let them drink ſeveral pints of poſſet-drink; then with a feather or finger put down the throat, let vomiting be provoked, iterate it often.

The day following the vomiting, unleſs any thing ſhall prohibit, let blood be taken out of the Arm, or from the Hemerhoid Veins with a Leech: then the next day after, let a purging medicine be taken, which afterwards may be repeated conſtantly four days every new Moon.

Purges. Take *Reſine af Jalop* ℈ ß, *Mercurius Dulcis* ℈ i. of *Caſtor* gr. iii. of *Conſerve* of the *Flowers of pæony* one ounce, make it into a *Bolus*. Take *pill fætida* the greater ℈ii. of *Hyſterica* what will ſuffice, make thereof v. pills. Take of the ſtrings of *black hellibore* macerated in Vinegar, dried and powdered half an ounce of Ginger ℈ß. of the *Salt of Wormwood* gr. xii. of the *Oyl of Amber* drops ii. make a powder, let it be given in the Pap of an Apple. Take of the powder of *Hermodactils* compound one ounce, of *humane Skull* prepared gr. vi. make a powder, let it be given in a draught of the *decoction of hyſſop* or *Sage*.

On thoſe days that they do not purge, eſpecially about the time of the changing of the Moon, let there be adminiſtred Specifick Remedies morning and evening, which are ſaid to cure this diſeaſe, with a certain innate and ſecret virtue: of theſe there are extant a very great company, and are preſcribed in various forms of Compoſitions.

Speciſicks. The moſt ſimple Medicines which experience hath found to be very Efficacious, are the *Root of the male Pæony*, and the *ſeeds* of the ſame. Take of the *Root of the male Pæony* dried and powdered one ounce, to ii. or iii. let it be given twice a day in the following Tincture. Take of the *leave of Meſletow* of the *Oak* two ounces, of the *root of Pæony* ſlic'd half an ounce, of *Caſtor* one Ounce; let them be put into a cloſe Veſſel with ſimple water of *Betony* or *Pæony*, and white-wine, each ℔ i. of the *Salt of Miſletow* of the *Oak* or the *common Miſletow* two Ounces, let them digeſt cloſe in the hot ſand for ii. days, let them take three Ounces with a doſe of the aforeſaid powder.

Poor people may take of the aforeſaid powder in a decoction of *Hyſop* or *Caſtor*, made with fair water and white-wine.

At the ſame time let the *Root of Pæony* be cut into little bits, and being ſtrung upon a thred, hung about the neck. Alſo let the Roots being fried in a pan, or boiled tender, be eaten daily with their meat.

Take of the *Root* and *Seeds* of the *male Pæony* each two Ounces, of *Miſletow* of the *Oak*, of the *hoof of Elk* one dram each let them be ſliced and bruiſed, and put into a thin ſilk bag, and hang at the pit of the Stomack.

Powders. Among the Specificks, this powder is greatly commended by many Authors. Take of *Caſtor Opoponax*, *Dragons blood*, *Antimony* and the *ſeed* of *Pæony*, each alike, make a powder, of which may be taken half an Ounce to one Ounce every morning, with wine or ſome proper decoction, or with *black Cherry water*.

Take of a *mans Skull* prepared one Ounce, of *Miſletow of the Oak*, of *Counterfeit Cinaber*, of an *Elks Claw*, each half an Ounce, ſo mingle them. The doſe is ℈ ß. to a Scruple.

If the form of powder be diſtaſtful to any one, or if it ſhould become loathſome by the long uſe of it, *Electuaries*, *Pills*, *Troches*, *Spirits*, and *Elixirs*, each of which agree with ſpecifick medicines, are wont to be preſcribed.

Electuaries. Take of the *Conſerve* of the *male Pæony*, of the *Lilly* of the *Valley* each three Ounces, of the *ſeed* and *root* of the *male Pæony* powdered each ʒ ii. prepared *Coroll* ʒ i. of the powder of *Pearls*, and of *humane Skull* prepared, each two ſcruples, of the *ſalt* of *Miſſletow* of the *Oak* ʒ i. ß. with what will ſuffice of the *Syrop* of *Corall*, make an *Electuary*, let them take of it morning and evening, the quantity of a Nutmeg.

Take of the Powder of the *root* of the *male Pæony* one Ounce, of the *ſeeds* of the ſame half an Ounce, of *Miſletoe* of the *Oak*, of an *Elks claw*, of *humane Skull*, prepared each two drams; of the *roots* of *Angelica*, *Contrayerva*, *Vergmian Snakewood*, each ʒ i. of the whiteſt *Amber*, of *Calcined Corall* each ʒ i. of the *Common ſort of Miſletow*, ʒ ii. of *Sugar Candy* eight ounces diſſolved in what will ſuffice, of the *Antiepileptical water of Langius*. Make a Confection, of which take twice in a day the quantity of a Nutmeg.

Pills. Theſe Powders, by adding to them the *Salt of Amber*, and *harts-horn*, with what will ſuffice of *Balſome Capivi* may be formed into a *pillurary Maſs*, of which may be taken iii. or iv. pills, in the morning and evening, drinking after them a draught of ſome appropriat Liquor.

Or

Or of thoſe ſorts may be prepared an *Elixir*, of which may be taken viii. drops to x. twice in a day, in a ſpoonful of a proper *Julup*, drinking a little of it after it.

Elixir. Take of *Hungarian Vitriol* vi. Pints, let them be diſtill'd with a Glaſs retort in hot ſand for 24 hours, then let the ſame retort, being defended or done over with Clay, be put with a large receiver in a reverberating Furnace, that the acid ſpirits may be forced with a moſt ſtrong fire, till they come forth. The whole Liquor being diſtilled, let it be drawn off in hot ſand, in a leſſer Glaſs retort, and let there be poured into the *Matrace*, of the *roots of Male-Pæony* cut into pieces and dried, four Ounces of the *ſeed* of the ſame, one Ounce of *humane Skull* prepared, of *Elks claws* and *red Coral* each half an Ounce, *Miſſletow* of the *Oak* ii Drams, let it digeſt with a gentle heat for ſeveral days, to the extraction of a tincture, the Liquor being decantated, let it be drawn off in a Glaſs retort to a third part remaining: being ſtilled forth, keep it by it ſelf: to thoſe remains, pour of the rectified ſpirit of Wine a little quantity, impregnated with the infuſion of the ſame ingredients, and let it digeſt for ſix days in Horſe dung, the Doſe of which is half a Scruple to a Scruple. The diſtilled Liquor may be given from half a ſpoonful to a whole ſpoonful, for the ſame intentions.

Or let there be prepared an Oil, out of the *Salt of Venus*, or *Copper*, according to the deſcription of *Henry Van Heers*, and given as there preſcribed.

Emperical Remedies. Among the ſpecifick Remedies, which (when the former ſhall not be profitable) ought alſo to be tried, are the *Livers of Frogs*, the *Gall of a Boar* dried with Urine, the Powder of *Bryony Root*. The Powder of a *Cuckoe*, of *Crows*; the *Runnet* and *Lights* of a *Hare*, the *Liver of a Wolf*, *ſtones taken out of Swallows*, the *Liver* of a *Kite*, the *Eggs* of *Crows*; with many more, to be daily taken with Food or Medicine; a famous Catalogue of which is extant of *Henry Van Brays*, a Phyſician of *Zutphen*: and from which preſcripts for poor people may be taken, eaſie to be prepared, and without great coſt.

Whilſt theſe kind of Remedies are to be taken inwardly, according to the aforeſaid method, ſome outward adminiſtrations being applied, bring help, and are deſervedly admitted to part of the cures; therefore, always Iſſues are made in this Diſeaſe, in one fit place or other; and alſo more often Veſicatories or Bliſters.

Amulets. *Amulets* hung about the Neck, or born at the pit of the Stomach, are thought to be uſeful: The freſh *Roots of Pæony* cut into little ſquares, and being ſtrung like Bracelets, and hung round about the Neck, and as ſoon as they are dry, let new be put in their places, and they being reduced to Powder, may be taken inwardly: Take of the *Roots* and *Seeds* of *Pæony* each ii. Drams, of an *Elks Claw*, and *humane Skull* prepared, each one Dram, of *Miſſletoe* of the *Oak* half a Dram, let them be beaten into groſs Powder, and ſewed in a piece of red Silk, and like a little bag, let it be hanged about the Neck.

An *Amulet* of a *ſtalk* of the *Elder*, found growing in the *Willow-tree*, is greatly commended.

Plaiſters. It agrees with ſome, to have their heads ſhaven, and a Plaiſter applied to the forepart. Take of the *root* and *ſeeds* of *Pæony*, of *Caſtor*, *Miſſletoe* of the *Oak*, of *humane Skull* moſt finely Powder'd, each one Dram, of *Bettony* Plaiſter two Ounces, *Caranna*, *Tacamahacca*, each two Drams, *Balſum Capive*, what will ſuffice, make a maſs, and let it be ſpread upon Leather, make a Plaiſter for the ſuters of the Head.

Let the Temples and Noſtrils be often anointed with *Oil of Amber*, by it ſelf, or mixed with *Oil Capive*.

Sternutories or ſneezing powders. *Sneezing Powders*, and ſuch as purge the Head of *Rhume*, are to be uſed daily in the Mornings: Take of *white Hellebore* one Dram, of *Caſtor*, and *Euphorbium*, each half a Dram, the *Leaves* of *ſweet Marjorum*, and *Rue*, each two Drams, make a Powder; make a decoction of *Sage* or *Hyſſop*, with *Muſtard* diſſolved in it, with which gargle the Mouth and Throat.

A Gliſter may be ſometimes uſed, as need ſhall require.

Sometimes the more ſolid Medicines are to be moiſtned with liquids, or they ought to be drunk after them, for which end Diſtilled waters ſhould be at hand, *Julups*, *Tinctures*, or *Decoctions*; which are endued with a certain Specific virtue againſt this Diſeaſe.

Diſtill'd Water. Take of *Hungarian Vitriol* four Pound, of the Powder of freſh *human Skull*, four Ounces, of the *root* of *Pæony* ſliced, ſix Ounces, let them be bruiſed together in a Morter, put to them either of *Spaniſh-wine*, or ſmall *white-wine*, or *wine* made of the juice of *black-Cherries*, a quart; being fermented in a Veſſel, let it be diſtill'd in a Glaſs-retort, in hot ſand.

Take of the ſhavings of *Box-wood*, of *Hungarian Vitriol*, each two pound, of the *Miſſletoe* of the *Oak*, or the *common Miſſletoe* leaves, three handfuls, of *Rue* two handfuls,

fuls, being bruised together, put to it of *Spanish-wine*, four pints: Let them be distill'd in a Glass Cucurbit, with hot sand.

Julups. Take of common *Vitriol* six pound, of the *root* of the *Male Pæony* six Ounces, of the *Misseltoe* of the *Oak* one Ounce, of *green Walnuts* eight Ounces; being cut and bruised, let them be distilled in a Glass-pot, a *Glass Alembick* being placed upon it, in hot sand. Take of this Liquor one pint, of *black Cherry-water*, and of the *water* of the *flowers* of the *Toil*, or *Line-tree*, each half a pint, of *white-Sugar* four Ounces, mix them, and make a *Julup*; the Dose two Ounces to three Ounces, twice or thrice in day.

Oxymel of *Squils*, also an *hony decoction* with *Hyssop*, are much praised by the Ancients. Or an *Apozem* of this kind may be prepared, of which may be taken four Ounces, to six or seven, twice in a day.

Apozems. Take of the *roots* of *Male Pæony*, *Angellica*, *Imperatoria*, *Valerian*, each six Drams, of the *leaves of Betony*, *Sage*, *Lilly* of the *Valley*, *Penny-Royal*, each one handful, of the *seeds* of *Rue*, *Nigella*, each three Drams, *Pæony* half an Ounce, of *Raisins* three Ounces, of *Liquorish* half an Ounce, being cut and bruised, let them be boiled in six pints of *Spring-water*, to the consumption of the third part. Towards the end, add of *black Cherry-wine* half a pint, or ten ounces, strain and keep it in close Vessels. The Dose is from six to eight Ounces, twice in a day, after the afore-prescribed Remedies.

Or the aforesaid ingredients, excepting the *Liquorish*, and *Raisins*, may be boiled in six pints of *Hydromel*, or *Water* and *Hony*, or *Meath*, to the consumption of the third part. The Dose four to six Ounces.

Great Remedies. If that the aforesaid method, consisting in the use of *Catharticks*, and *Specificks*, being for some time tried, and altogether in vain, you must come to Remedies of another kind, and chiefly to those called Great, or Notable: In this rank are placed *Diaphoreticks*, *Salivation*, *Bathes*, and *Spaws*.

Alphonsus Ferrius affirms, That he had cured many Epileptical people, with a decoction of simple *Guaicum*, being prescribed twice in a day, and taken to six or eight Ounces, and its second decoction drunk (as in the cure of the *Pox*) instead of ordinary drink. If to such a decoction the *roots* of *Pæony* and other Specificks should be added, perhaps it would be more efficacious. It seems probable, that a *Salivation* strongly excited from *Mercury*, and afterwards a *Sudoriferous* or *Sweating-Diet* following, might certainly cure this Disease. What *Baths*, or *Spaw-waters* are able to do, I have not observ'd, either by my own or others experience. Perhaps I have made trial, that our Artificial *Spaws* sometimes have been available in curing the Epilepsie, to wit. both those impregnated with *Iron*, and also with *Antimony*, and taken in a great quantity for many days.

CHAPTER IV.

Of other kinds of Convulsions, and first of the Convulsive Motions of Children.

After the Epilepsie, as it were the principal Spasm, in the chief place excited, to wit, within the middle part of the Brain; the other kinds of Convulsions come to be treated of in order. The differences of those are best taken from a twofold kind of cause, and the various manners and accidents of either. We have already shown that all Spasmodic Distempers do flow either from the meer irritation of the spirits, or from their explosion, by reason of the cleaving of an Elastick *Copula* to them, or jointly from both together: wherefore, the manifold Ideas of Spasms may be distinguished, and distributed into certain Classes, as it happens for this or that cause, or either together, to remain in the various places of the *Encephalon*, or the Nervous Appendix. For indeed, the Spasmodic matter, or the Explosive *Copula* of the spirits, finding a passage chiefly, and most often thorow the Brain, and sometimes in some measure thorow the extremities of the Nerves, subsists either about the origine of the Nerves, or their middle processes, or their outmost ends, or abounds in their whole passages, as shall be by and by more particularly declared. Further an irritation stirring up Convulsions by it self, or with a previous remote cause, although it be made every where in the Nervous stock, yet it chiefly, and more frequently produces such an effect, about the beginnings,

beginnings, middle proceſſes, and foldings, or ends of the Nerves. But the ſame kind of cauſe and effects, are after one manner in Infants and Children, and another in Youths, and thoſe of riper age. Since therefore we have determined, particularly to conſider all the kinds of Convulſions, we will firſt diſcourſe of the Convulſive motions of Infants and Children.

Infants and Children happen ſo ordinarily, and frequently to be tormented with Spaſmodic Diſtempers, that this is rekoned the chief, and almoſt the only kind of Convulſions; for the ſymptoms of this kind, in other more ripe People, are wont to be called by other known Names, and referred to the Epilepſie, Hyſterick, Hypochondriack, Collick Paſſions, or alſo to the Scurvey: but in Children they are called, as it were by way of excellency, Convulſions.

As to this we muſt obſerve, that Children are found to be greatly obnoxious to Convulſions, chiefly about two ſeaſons, to wit, within the firſt Month after they are born, or about their breeding of Teeth: Although it often happens, that the aſſaults of this Diſeaſe may come alſo at other times, and from certain other cauſes.

In the firſt place therefore, it very often happens that Children newly born, or at leaſt ere they are two Months old, are afflicted at every turn with Spaſms, excited in divers parts; for that inverſions of the Eyes, diſtortions of the Cheeks and Lips, or tremblings, yea contractions of the Tendons, and frequent jerkings or leapings forth of the Members, and ſudden ſhakings of the whole Body infeſt them; and that the ſame effect likewiſe ſometimes afflicts the *Præcordia*, appears plain enough, becauſe whilſt the Spaſms buſie the Limbs, and outward Members, alſo the Face becomes now pale, now of a livid, or dead colour, from the Blood ſtagnating in the Heart, and the Lungs being at that time contracted. As therefore, Spaſms are wont to infeſt three regions of the Body in Children, to wit, the parts of the Head and Face, the outward Members and Limbs, and the *Præcordia* and *Viſcera*, we obſerve now theſe regions, now thoſe, now two, or all together to be poſſeſſed, by the Morbific cauſe, to wit, as it is fixed, either about the beginnings, or ends of the Nerves; and when the former of theſe happens, as the ſuperior part of the oblong pith, the middle, or the loweſt part of the ſpinal marrow is touch'd, one or more parts together are aſſaulted by the Morbifick cauſe.

As to the other cauſes of this Diſtemper, to wit, the procatartic and evident, thoſe of the former kind, do chiefly conſiſt in two things: Firſt, that all the parts of the Head in Infants are very weak, and abound with a viſcous humidity; to wit, the Brain leſs firm, and the tone of the Nerves very looſe, ſo that they are not able to bear the more light force of every matter, but the ſpirits inhabiting them, are eaſily incited into irregular Motions or Spaſms, by the proper Liquor, wherewith thoſe parts are watered, if it flows never ſo little immoderately, or at leaſt more plentifully, than for the meaſure of ſo little ſtrength. But in the ſecond place, becauſe it appears by obſervation, that Children, not only, nor all, who are of a more tender Conſtitution, are found to be prone to this Diſeaſe, therefore this ought to be rather accounted for a reaſon of the more remote Morbid cauſe, that the Blood, and Nervous Juice, are originally vicious in ſome Infants, by reaſon of evils contracted from the Womb: For that the ſanguineous maſs, wanting eventilation for many Months paſt, becomes impure in Children newly born; wherefore, broad and red puttings forth, like the ſmall Pocks, ſhew themſelves through the whole skin, in moſt Children, ſoon after they are born; to which ſort of wealks, or effloreſcences, if they are hindred or repreſſed, oftentimes dangerous exulcerations, about the parts of the mouth follow. Hence we may deſervedly ſuſpect ſuch impurities of the blood, ſometimes to be poured forth into the brain and nervous ſtock, conſidering their debility, and for that reaſon Spaſmodic Diſtempers to ariſe; to wit, whilſt the blood being vicious from the Womb, endeavours to purifie it ſelf, it transfers it fæculencies into the Head, which were wont to be exterminated by the putting forth the red gum, or red ſpreadings thorow the skin: Wherefore, a water now thin and ſerous, now thick and ſticking, and either participating of preternatural Salts and Sulphurs, is laid up within theſe or thoſe receſſes and cavities of the Brain, Cerebel and oblong pith, the recrements of which, when they begirt the beginnings or ends of this or that Nerve, and ſometimes many together, affix on the ſpirits inhabiting them Heterogeneous Particles, and apt for Spaſmodic or Convulſive exploſions. For as ſoon as the Nerves have deeply imbibed ſuch Particles, the ſpirits being burthened with their *Copula*, endeavour either of their own accord, or being incited by evident cauſes, to thruſt and ſhake it off; and ſo they enter into Spaſmodic or Convulſive exploſions.

The evident cauſes, which bring on Convulſive motions in Children prediſpoſed, are of two kinds, *viz.* In the firſt place, whatſoever ſtir up unwonted effervеſcencies of the

the blood, whether they be excesses of heat or cold, a too plentiful nourishment, or hotter than should be, the changes of the Air and Weather, and chiefly the periodical times of the Moon; for by reason of these, and other the like occasions, the Blood growing more hot than by right it should be, affixes sooner to the spirits an Heterogeneous *Copula*, even to a fulness, and causes it presently to be struck off and exploded, by them throughly disturbed. Secondly, An irritation in almost every part of the nervous System, does not seldom bring into act, a Spasmodic or Convulsive Disposition: wherefore, not only an excess of tangible qualities outwardly inflicted, but the milk Coagulated in the stomach, choler, or other sharp humors, or also Worms knawing the Intestines, are wont to excite Spasms or Convulsions: Besides, these kind of evident causes, as they are stronger, sometimes induce Spasmodic Distempers of themselves, and without a previous disposition: even so Worms, and perchance sharp humors, cause Convulsive motions to some Children, at least to the more tender.

That it might more certainly, and to the sense appear, what kind of Morbific matter might be in Convulsive motions, I have opened the dead bodies of many which this Disease had oppress: I have always in vain sought the cause within the Viscera, and first passages of Concoction; In the heads of many, a serous water being heaped up, within the Cavity, under the Cerebel, and distending the Membrane which clothes the oblong pith or marrow, did overflow the beginnings of the Nerves: in some, no footsteps of this Disease appeared: so that, what sticking to the spirits did irritate them into explosions, was of so imperceivable a bulk, and its original so altogether hid, that it could not be found out by the most perspicatious scrutiny of the sight. Sometime past, in this City, many Children of a certain Woman died of this Disease, at length the fourth, as the others, died within the Month; we dissected the Head, and here no serous Colluvies or Water did overflow the Ventricles, but only the substance of the Brain, and its Appendix, was moister than ordinary, and looser; what was most worthy of observation, was, that in the Cavity, which lies under the Cerebel, upon the trunk of the oblong pith, we found a remarkable heap of clotter'd, and as it were concreted blood: but in truth it is uncertain, whether this matter deposited there from the beginning, had primarily caused the Convulsions; or rather, whether this blood being extravasated and expressed, by the contraction of the parts planted round about, was not the effect and product of the Convulsions, and not the cause of them; for also in Apoplectical people this kind of Phænomenon ordinarily happens; which yet we shall afterwards shew to be rather the effect, than the cause of the Disease.

Indeed, the Heterogeneous Particles, which flow to the Blood, from the Womb, are wont to be sent away through Efflorencies or Cutaneous Pustles in the whole Body in many Children, in others being poured on the head, are the material cause of the Convulsive Distemper, may be inferred, besides the reasons before recited, from the Remedies chiefly helping: For that in little Children, obnoxious to this hereditary Disease, the Convulsive Fits are best prevented, if that an Issue be made presently after they are born in the nape of the Neck, and blood drawn with a Leech from the Jugular Veins; for the corruptions of the Nervous Juice, are brought away by that, and the impure buddings of the blood, are diverted from the head by this: by these ways of administrations, when before two or three Children, of the same Parent, have died of Convulsions, soon after they were born, all the rest have been freed from the same evil.

Secondly, Thus much concerning the Convulsive motions of Children, which are wont to infest them, by reason of an Infection contracted from the Womb. If that at this bout they should escape the Disease it self, or at least its deadly strokes, nevertheless, about the time of breeding Teeth, they would be found at last to be obnoxious to the same danger: for when the Teeth, especially the greater, are about to cut, oftentimes a Fever is excited, to which not seldom Convulsions are joined: and though at this time Children are grown stronger, and may better bear the fits of the Disease, than when new born, yet the Convulsive Distemper, now stirred up by no other grievous occasion, becomes very dangerous, and sometimes deadly.

But forasmuch as Children, who fall into Fevers about the time of breeding of Teeth, are not all tormented with Convulsions, it therefore follows, that some disposition to this Disease, either innate, or acquired, doth proceed; and that the pain caused from the breeding the Teeth, is to be esteemed only the means of a more strong evident cause, to wit, Children, who being indued either with a Cacochymia or Juice, causing ill digestion, or with a more weak constitution of the brain and nervous stock, have their animal spirits too much adulterated, or dissipable, are sometimes disposed for the coming of Convulsive Distempers: wherefore, when so acute pain, together with a Fever, afflicts, that latent disposition is brought into act.

If

If it be here asked, for what reason a fever, and then Convulsive Motions following thereupon, come to those prediſpoſed, in teething, it may be anſwered, that either effect may be attributed to the pain, as the immediate cauſe: We experimentally know by our ſelves, what the torment is, that follows an irritation about the roots of the Teeth; in truth ſo great and ſo cruel, that a more cruel can ſcarce be; for that one or two notable ſhoots of the fifth pare of nerves, reaches to the roots of each Tooth, which when it is hauled by the ſharp particles of the Blood, or other humors, there laid up, cauſes a moſt ſharp ſenſe of trouble, or pain by its Corrugation: But this kind of Vellication or hauling of this Nerve, happens thus to children breeding teeth, becauſe that the membranes and fibres are every way diſtended by the Teeth, now increaſing into a greater bulk, and as yet included within the ſcarce hollow gums: hence the blood being hindred in its Circulation, cauſes a tumour, and ſo preſſes the nerves, and alſo pours on them the more ſharp particles of the Serum, by which being notably pulled or hauled, they are tormented with Corrugations, and painful Spaſms.

Therefore, when ſo cruel pains happen to children from their breeding Teeth, it is no wonder if a feaver, and alſo convulſive motions ſometimes follow: the former of theſe happens, both for as much as the blood being hindred about the pained part, is not circulated with its wonted and equal courſe, wherefore it becomes inordinately moved, in the whole body; and beſides, becauſe Spaſms being ſtirred up ſomewhere in the nervous ſtock, the corrugated and contracted nerves, preſs together, and pull the arteries, and by that reaſon, ſtir up irregular and feveriſh fluctuations in the blood. But ſometimes Convulſions happen in breeding Teeth, both becauſe the blood growing hot, ſends forth heterogeneous particles, to the animal government, and ſo ſtirs up the ſpirits into exploſions; and beſides alſo, when this acute pain, and as it were a lancing, follows upon the teeth being about to cut, it communicates a very troubleſome and irritative ſenſe, from the affected parts, to the firſt ſenſory, preſently from thence, the motion of the rage is retorted by the ſame or other neighbour Nerves, which by reaſon of a previous diſpoſition, doth not rarely become convulſive.

Beſides theſe two occaſions of Convulſions (which are wont to be chiefly, and more often in children) to wit, the times of Infancy and breeding Teeth, this Diſtemper alſo is excited at other times very often, and for other cauſes: For in whom the Seeds of the Spaſmodick Diſpoſition is ſown, they ſometimes unfold themſelves preſently after the birth, and are ripened into morbid fruit; or elſe lying hid for a while, they now come before the breeding of Teeth, and follow a long time after it; and by reaſon of other evident cauſes, to wit, either external or internal; of which ſort are a ſickly, or breeding nurſe, milk Coagulated in the ſtomack, or degenerating into an acid or bitter putrifection, a feveriſh diſtemperature of the head, ulcers or weakſ of other parts ſuddenly vaniſhing, the changes of the air, the Conjunctions, Oppoſitions, and aſpects of the Sun and Moon, and ſuch like; they at length break forth into Act, from an uncertain event. Concerning theſe, there is no need, that we ſhould particularly diſcourſe.

When all the Children of a man dwelling in the neigbourhood, died of Convulſions, within the ſpace of three months, at length to prevent that fatal event, they ſought for remedies, for a child newly born: I being ſent for, a few days after the being brought to bed, firſt adviſed the making an iſſue in the nape of the neck, then, that the next day after, a leech being applied to the jugular vein of each ſide, two ounces of blood ſhould be taken away: Beſides, that about every conjunction, or oppoſite aſpect of the Sun and Moon, about five grains of the following powder ſhould be given in a ſpoonful of Julap, for three days, morning and evening. Take of humane Skull prepared, of the root of the male pæonie, each one dram, of the powder of Pearls half a dram, of white ſugar one dram, mingle them, and make a very fine powder. Take of the waters of Black Cherries three ounces, of the antiepileptic of *Langius* one ounce, of the ſyrrup of the flowers of the male Pæony ſix drams, mingle them; alſo I ordered that the nurſe at the ſame times, ſhould take a draught of whey, or poſſet drink, in which were boiled the ſeeds and roots of the male Pæonie, and the leaves of the Lilly of the Vally; the Infant for about four months was well, but then began to be troubled with Convulſions: at which time, the ſame remedies being adminiſtred both to the child, and to the nurſe, in a larger doſe, Veſicatores alſo were applied behind the ears, and blood was taken by the ſucking of a Leech, from the jugular veins: within two or three days the child grew well: afterwards, whenever within four or five months the Convulſions returned, it was cured again, by the uſe of the ſame Remedies. After half a year, the convulſive motions wholly ceaſed, but a painful Tumour aroſe, about the lower part of the *Spinæ dorſi* or back-bone, from which proceeded a certain diſtor-

tion of the *Vertebræ*, or joints of the back-bone, and a weakneſs of the legs, and at length a Palſie. It ſeems in this caſe, that the Spaſmodic or convulſive matter, being wont to come upon the brain firſt, and beginnings of the nerves, entring at laſt the Spinal marrow, and being thruſt out at its further end, it wholly ſtopt up the heads of the appending nerves, and ſhut out the paſſage of the Spirits: to wit, becauſe other narcotick and more thick, had joyned themſelves to the exploſive particles.

The Curatory Method againſt the Convulſive Diſtempers in Children.

IT is to be endeavoured either to prevent the Convulſive paſſions, threatning Children and infants, or to cure them being already begun.

The Preſervation of Infants from Convulſions.

For if the former children of the ſame parent, were obnoxious or liable to Convulſions, that evil ought to be prevented timely, by the uſe of of Remedies to thoſe born after. It is uſual for this end, to put into the mouth of the child newly born, ſome antiſpaſmodick Remedy, aſſoon as it begins to breath: from hence ſome are wont to give them ſome drops of the pureſt hony, others a Spoonful of Canary ſweetned with Sugar, and ſome again oyl of Sweet Almonds freſh drawn, to ſome may be given half a Spoonful of epileptic water, or one drop of oyl of Amber.

Beſides theſe firſt things given to Infants, which certainly ſeem to be of ſome moment, certain other Remedies and means of Adminiſtrations ought to be uſed: to wit, let one ſpoonful of Liquor proper to this diſtemper, be drunk twice a day: as for example: Take of the water of black Cherry and of Rue each an ounce and a half; of the *Antiepileptic of Langius* one ounce; of the *Syrrup of Corral* ℥ vi. of prepared *Pearl*, *gr.* xv. mix them in a Viol. On the third or fourth day after the birth, let an Iſſue be made in the nape of the neck, then if it be of a freſh countenance, let a little blood to about an ounce and a half, or two ounces be taken by the ſucking of Leeches, from the jugular veins, having a care leſt the blood ſhould flow out too plentifully in its ſleep; let the Temples, and the hinder part of the neck be gently rub'd with ſuch a like oyntment. Take of the oyl of Nutmegs by expreſſion ℥ ii. *of Capive* ℥ iii. *of Amber* ℈ i. Let an Amulet be hung about the neck, of the roots and ſeeds of the greater *Pæonie*, a little of the hoof of an *Elke* being added to it.

The Method of Curing to be uſed to the Nurſes.

Moreover antiſpaſmodick Remedies, ſhould be daily given to the Nurſe; let her take morning and evening, a draught of whey or poſſet-drink, in which the roots and ſeeds of the male *Pæonie*, and ſweet fennil ſeeds are boiled. Take of the *Conſerve of the flowers of Betony*, of the male *Pæonie*, and of Roſemary each ii. ounces; of the powder of the Root and flowers of the male *Pæonie*, each ℥ ii. of red *Corall*, prepared, and of the whiteſt *amber*, each ℥ i. of the roots of *Angelica*, and *Zedoarie* prepared each ℥ ß. with what will ſuffice of the *Syrrop of Pæonie*, make an Electuarie; let her take morning and evening, the quantity of a Nutmeg.

Take of the powder of the *root* of *male Pæony* ℥ ii. the *ſeeds* of the ſame ℥ i. make a powder; of the whiteſt Sugar three ounces diſſolved in the water of the *flowers* of the *Line-tree*; and boiled to tablets, of the *oyl of Amber* ℈ i. make tablets according to Art, each weighing ℥ ß. let her eat one every ſixth hour. Alſo let her keep to an exact diet.

The Cure of Infants ſick with Convulſions.

If any Infant be actually afflicted with Convulſions, becauſe that an Iſſue operates little and ſlowly, it will be expedient to apply bliſtering plaiſters to the nape of the neck and behind the ears, and unleſs a more cold temperament ſhould gain-ſay it, let blood be drawn with Leeches from the veins: let Liniments be uſed about the Temples, Noſtrils, and hinder part of the Neck, and plaiſters alſo laid to the bottoms of the feet; Clyſters that may keep down the belly, ſhould be daily adminiſtred: beſides let ſpecifick Remedies be inwardly taken, often in a day, to wit, every ſixth or eighth hour.

Oyntments.

Take of the *oyl Capive*, of *Caſtor* each ℥ ii. of *Amber* ℥ ß. make a Liniment.

Take of the plaiſter of *Oxycrocia* two parts, of diſſolved *Galbanum* one part, of *oyl of Amber* ℈ i. make a plaiſter for the ſoles of the feet. Let there be given of the powder of *Ammoniacum*, according to the deſcription of *Riverius*, twice or four times in a day.

Powders.

Take of *humane skull* prepared, of the *ſeeds* of *Pæony*, of an *Elks claw*, of *Pearls* prepared, each ℥ ß. of *Amber greeſe*, gr. vi. make a powder; the doſe vi. grains, in a ſpoonfull of the Liquor hereafter deſcribed, three or four times in a day.

Or

Or take of *humane Skull* prepared, of pearls each ʒß. of the *Salt of Amber* ℈i. of the *Sugar of Pearl* ʒi. the dose ℈ ß.

Or take of the *Spirits of harts-horn* iii. drops, let it be given every sixth or eighth hour in a spoonful of the Julup below prescribred.

To the children of the poor, may be administred the *powder* of the *Roots* of *wild Vareian* ℈ß. to ℈i. let it be given twice a day, in a spoonful of milk, or appropriat Liquor.

Untzerus greatly commends the Gall of a sucking Whelp, to wit, that the whole juice of the gallie Bag being taken forth, be given to the child to drink, with a little of the water of the *flowers* of the *Tile*, or *Line-tree*.

A learned Physitian lately told me, that he had known many cured with this Remedy: Besides, Empericks are wont to cause the bigger children, after they have drank the gall, to eat also the Liver of the Whelp broiled.

Julups, distilled waters, and other appropriat Liquors, may be prepared, after the following prescripts. *Liquors.*

Take of *black Cherry water* three ounces, of the *Antiepileptical water* of *Langius*, one ounce, of perlate sugar, ʒii. mix them.

Take of the green *Roots* of the *male Pæonie* cut into little pieces, six ounces, of *Hungarian Vitriol* eight ounces, of *humane Skull* two ounces, of the *Antiepileptical water* of *Langius* half a pint, mix them, and let them be distilled in a glass retort, in hot sand, the dose i. spoonful to ii.

Take of the fresh roots of the *Male Pæonie* cut, four ouuces, being bruised in a Marble Morter, pour to them of Spanish-wine, *lib.* i. make a strong expression, add of *manus Christi* pearled, half an ounce, let it be kept in a close glass. The dose i. Spoonful, or ii. twice in a day.

When Convulsive motions happen by Reason of the difficulty of breeding Teeth, this Symptom as it is secondary and less dangerous, so the cure does not always require the first or chief labour of healing, but sometimes we are rather careful to remove it, by allaying the pain and the feverish Distemper; wherefore both the patient and the Nurse ought to use a slender and refrigerating Diet; the Teeth being about to break through the Gums, their passage should be made easie, by rubbing or cutting them; and also *Anodynes* should be applied to those swelled and grieved parts: Clysters and taking away blood are often used; it behoves to cause sleep, and to attemper the fierceness of the blood: sometimes antispasmodick Remedies are made use of, but the more temperate, and such as do not trouble the blood and humors, Vesicatories or blistering plaisters, because they aptly evacuate the *serum*, too much poured forth on the head, oftentimes bring help. *Convulsions by reason of breeding of Teeth.*

When childern are troubled with Convulsions, not presently after they are born, nor by reason of the cutting of their Teeth, but for other occasions and accidents; the cause of such a distemper, for the most part, subsists either in the head, or some where about the Viscera of Concoction. When the former is suspected as it is wont to be manifested by signs which argue a *Serous Colluvies*, too much heaped up within the Head, the former Remedies, already recited, ought to be given in a larger dose; besides, in those who are able to bear purging, sometimes a Vomit, or a light purge is prescribed: *Wine* and *Oxymel* of *squills*, also *Mercurius Dulcis*, *Rhubarb*, and *Resin* of *Jalop*, are of approved use. *Spasms or Convulsions caused from other occasions.*

As often as the cause of the Convulsive Distemper seems to be in the *Viscera*, either Worms, or sharp humours, stirring up the torments of the belly, are understood to be in fault.

Against Worms, a purge of *Rhubarb*, or *Mercurius Dulcis*, the *Resin* of *Jalop* being added, is ordained: sometime past, a Child being miserably afflicted with Convulsions that he seemed to be just dying, I gave him a dose of *Mercurius Dulcis* with *Resine* of *Jalop*; with his stools, which were four, he voided xii. worms, and presently grew well. *By reason of worms.*

Take of the *root of Virginian Snakeweed*, in powder ʒi. of *Coral calcined* to a *whiteness* ʒß. a powder ʒi. the dose from half a *scruple*, to one *scruple*, twice in a day, continued for three days, drinking after it a decoction of *Grass-roots*. Take of the species of *Hiera* ʒi. ß. of *Venice-treacle* ʒ ii. make a plaister for the bottom of the belly, or apply to the Navel a plaister.

If the Convulsive motions are suspected to proceed from an irritation of the Ventricle, and intestines, made by sharp humours, a gentle purging, either by vomit, or stool, or both successively ought to be. For this end, let them drink a gentle Emetick of wine of squills, or salt of vitriol; when even the sick are troubled with a striving to vomit of their own accord: but if the other evacuation, or downwards, shall seem better to be tried, they ought to take an Infusion of *Rhubarb*, or the powder, and *Syrrup* of *Succory* with *Rhubarb*, or of *Roses* with *Agaric* and very often by these Remedies, timely applied, I have seen the Convulsive Distempers in Children

to be cured: besides, in this case, Clysters are frequently used: but external Medicines are not to be omitted; to wit, Fomentations, Oyntments, Plaisters applied to the Belly.

Take of the *flowers* of *Cammomel* cut very small, two handfuls, let them be put into two little bags made of fine Linen, or Silk, which being dipped in warm Milk, and wrung out, may be applied successively to the abdomen, or lower region of the Belly.

Take of the tops or flowers of *Mallows*, in like manner, but small, let them be fried in fresh Butter, or Hogs Lard, and in the form of a Liniment, or a Cataplasm, applied to the Belly.

CHAPTER V.

Of Convulsive Diseases of Ripe age, arising chiefly by reason of the Nervous origine being affected.

ALthough Convulsive Distempers, which happen to those of riper years, being known by other Names, also are commonly reputed of some other stock, and are wont to be referr'd to the Passions called Hysterical, Hypochondriacal, or Colical, or to the Scorbute; yet if the matter be a little better considered, it will easily appear, that some Convulsive symptoms, both in Men and Women, do come from the brain, which Convulsions properly and truly challenge to themselves the Name: But these (as we have already mentioned) may be distinguished after a various manner, by the manifold seat of the Morbifick cause, but chiefly into these three kinds, *viz.* Into Spasms or Convulsions stirred up, by reason of the origine of the Nerves being chiefly affected; into others being stirred up, by reason of the extremities or ends of the Nerves being possessed by the Morbifick matter; and lastly, into such from whose head the Morbific Matter descending, fills the whole passages, or the most part of some certain Nerves, or of all together.

Three kinds of Convulsions hapning to those of riper years.

Distempers arising from the Nervous origine distinguished.

Therefore, that we may proceed to unfold the Convulsions arising from the beginnings of the Nerves being affected, take notice here, that the Morbifick matter besieging the beginnings of the Nerves, doth sometimes chiefly flow into the first pair of Nerves, to wit, which respect the Muscles of the Eyes and Face, and from thence the contractions and tremblings, now of the Nose, Cheeks, or Lips, now of the Eyes, or the distortions of the Mouth, follow. Secondly, Sometimes the wandring and intercostal pair do chiefly imbibe the Heterogeneous Particles; and then Inflations, or Contractions of the Abdomen and Hypochondria, and also the palpitation of the Heart, trembling, difficult and interrupted breathing, an intermitting pulse, and other symptoms of the middle, and lower Belly, do very much infest. Thirdly, But sometimes the Morbifick cause being placed lower, affects chiefly the spinal marrow, and therefore the outward members and limbs, are rendred obnoxious to inordinate leapings forth and contractions: Further, in very many cases of this nature, because the animal spirits being explosed about the origine of the Nerves, do inordinately leap back towards the *Encephalon*; for that reason, to all Convulsions almost being excited by this means, the *Vertigo*, also the scotomie or giddiness, the tingling of the Ears, and sometimes the amased insensibility or falling down of the spirits, are joined, or follow.

1 *According to the various Nerves being affected.*

2. *According to the various places of the same Nerves being affected.*

But as we may conjecture, from the various figures of the Convulsive Distemper, it seems, that the Convulsive matter hauling those, or these Nerves, or many of them together, is lodged either about their beginnings, only, so that the spirits in that place being often explosed, a frequent and very troublesome Vertigo arises, besides tremblings, and a short faintness about the *Præcordia*, swoonings and often leapings, and light contractions in the Viscera, or Muscles are felt. Or, Secondly, The explosive Particles being dilated to the beginnings of the Nerves, enter more deeply into their processes, and not seldom being slidden down into the Nervous foldings, belonging to the *Præcordia*, or the *Viscera* of the lower Belly, or also to the exterior members, procure there other as it were nests of Convulsive Distempers, that as often as the spirits about the Nervous origine are driven into explosions, presently fits, as it were Hysterical, Asthmatical, or otherways Convulsive, arise in the Abdomen, Thorax, or Limbs: Examples of these, and by what means they are made, shall be anon more clearly delivered: In the mean time, the Spasmodic matter flowing into the pipes of the Nerves,

when

when it is transfer'd even to their processes and remote enfoldings; yet, forasmuch as it hath still its chief mi e about the Nervous original, therefore after very grievous Convulsions of the Viscera or Members, a great perturbation of the Brain follows thereupon, with a tingling of the Ears, a Vertigo, and often an insensibility or amased excurtion of spirits: but sometimes the Morbific matter, as to the greatest part, being translated to the farthest ends of the Nerves, from thence they become free or clear about their beginnings: For I have observed many, who, whil'st at the beginning, they were infested with the Vertigo, often fainting away with fear, head-ach, and heaviness about the hinder part of the head, to have felt about the *Præcordia* or *Viscera*, only light inflations or tremblings; but afterwards, suffering more cruel Convulsions about these parts, they did not complain of the former Distempers of the Head.

By what means the Convulsive matter flows into the Nerves.

If it should be further demanded concerning the Convulsive matter, from what place it should be brought, and by what ways carried towards the beginnings of the Nerves, and what kind of settlement, and as it were cherishing nests it there obtains; we say, that although we cannot detect the footsteps and manifest passages of this matter, yet so much may be collected from certain observations, and the Analogie of things, it may be supposed there are these two distinct manner of passages, whereby the Convulsive Particles being first poured out into the Brain and Cerebel, from the Blood, are from thence carried towards the beginnings of the Nerves, *viz.* First, sometimes this matter being imbibed by the Brain and Cerebel, and by degrees passing thorow the pores of either, slides into the trunk of the oblong marrow, whose tract being also overcome by it, together with the nervous juice, it slides forward towards the original of the Nerves, and is heaped up near their heads, or within the medullarie trunk it self, or within the annularie Prominencies, in which places, either a long while subsisting, it stirs up frequent *Vertigoes*, and more light Convulsions, in remote parts as hath been said; or being slidden from thence, more deeply into the passages of the Nerves, excites fits of Convulsions very cruel: such a progress of the Morbific cause, we suspect in whom the vertigo, swooning, heaviness of the head, and torpor of the mind go before the Convulsive assaults: Indeed, the matter of the Disease, abounding as yet in the brain and marrowie appendix, produces these kinds of previous Distimpers; which being slidden from thence into the Nerves, causes Convulsions.

Secondly, There is yet another way, whereby it plainly appears, that the material cause of the Convulsive Distemper is transferred to the beginnings of the Nerves, to wit, when the same being deposited by the *serous water* within the cavities or ventricles of the Head, it is insinuated into the neighbouring roots of the Nerves: For in *Chronical* Diseases, when the remarkable discrasie of the blood and humors happens also to be accompanied with a praved disposition of the brain, oftentimes a great plenty of sharp *Serum* infesting the Nervous stock, dropping forth from the Vessels of the *Choroeidan*, or retiform enfoldings, slides into the ventricles of the brain, and its appendix: But this *serous water*, afterwards breaking thorow the under-spreading of the *Cerebel*, into the fourth Ventricle, the little skin there being displaced, whereby the oblong marrow is uncovered, it falls upon the beginnings of one or more of the Nerves, and either by irritating, or imbuing them, with Heterogeneous and Explosive Particles, induces the Convulsive disposition. And this for the most part is the cause that sick people, after long and ill handled Fevers, also after the more grievous *Cephalic* Diseases, at length die of Convulsions; as I have found by the frequent Anatomie of the Carcases of those who died by that means. Also it appears by Anatomical observation, That the brain may be overflowed by a certain *serous water* without the Distemper of the Convulsive disposition; and further, that in some, who died of the Epilepsie, and other Convulsive Diseases, there was no deluge of the *Serum*, within the Ventricles of the Brain: by which it is given us to be understood, that the Convulsive Distempers do not flow only from the watery matter in the Head; but that they arise not at all from such a cause, unless the *serous* water overflowing the Ventricles of the Brain, and chiefly that underlaying of the *Cerebel*, be imbued with Heterogeneous and Explosive Particles. I remember once, my Counsel to be ask'd for a young man labouring with an egregious Phtisis, and at that time truly desperate, besides a Cough, and shortness of Breath, he had grievously complained for many days, yea weeks, that he could not lie upon his back in his bed, or whilst he sat in a Chair he could not lean his head backwards: for that by this, or that posture of his Body, he was wont presently to suffer tremblings of his heart, and a fainting of the spirits, as if he were just about to die: wherefore of necessity he was fain to hold his head upright, or leaning forward. After he was dead, his Carcase being dissected, his Lungs appeared all over tumified, and in some places Ulcerated: then his Skull being opened, there flowed within all the *Ventricles* of the brain, a great quantity of yellow and salt *Serum*:

which

which water certainly whilst it did slide forward upon the fourth *Ventricle*, about the trunk of the oblong marrow, his head leaning back, rushing upon the heads of the wandring and intercostal pair of Nerves, did stir up the aforesaid Convulsions about the *Præcordia:* but so long as his head was inclined forward, that the heap of *Serum* flowed back into the interior *Ventricles* of the Brain, the origine of the Nerves remained free from that Convulsive matter.

Having hitherto shown how many ways, and by what passages the morbific matter, being dilated towards the origine of the Nerves, seems to bring on Convulsions, it were easie, according to these reasons, to unfold many Convulsive symptoms: for besides the Convulsive motions of Infants and Children, oftentimes excited from the same kind of causes; hither may be refer'd the contractions, and sudden leapings forth of the nervous parts, which follow upon Fevers. As also those Passions commonly called *Hysterical*, also *Hypocondriacal*, and certain others, proceed not seldom from the *Morbific* cause, rushing upon the beginnings of the Nerves. We will therefore endeavour to establish the truth of this *Hypothesis* by some other Histories and examples of sick people; but in the first place, we will propose observations of that kind, in whom the Morbific matter setling upon the beginnings of the Nerves, and not being as yet slid deeply into their processes, induced frequent *vertigoes*, and only more light Convulsions of the *Viscera* and *Præcordia*.

1. *Observation.* A Noble Woman about 30 years of Age, of a tender constitution, and lean in Body, was wont every winter to be grievously afflicted with a *Catarh* or Rhume flowing upon the wind-pipe and Lungs, with a hoarse Cough, and great spitting; but the last year, great care and diligence being used, she avoided that evil. But after the winter Solstice, having taken cold, she was troubled with an huge pain of the head, a tingling of the Ears, a giddiness, with a great defluxion upon the Eyes, that it easily appeared, that the heap of *Serum*, which before this time was wont to distil into the Breast, was now wholly laid up, within the head and brain: besides, an effect of which was, that as often as she began to sleep, she was greatly infested with Passions, as it were *Hysterical*, to which she had never been before obnoxious: For when ever, being sleepy, she closed her Eyes, presently a bulk ascending in her belly, a choaking in her throat, tremblings, and leapings about the *Præcordia*, were stirred up; which affections notwithstanding quite ceased, when she was thorowly awakened, so that the sick party was necessitated to abstain almost altogether for many days and nights from sleep.

Being sent for to this Lady, after she had been sick and weak for many days, I was compelled at length to use gentle Medicines: therefore I took care that blood should forthwith be drawn from the foot, to four Ounces, and every day a Clister of Milk and Sugar to be administred, by which she was wont to have three or four stools: besides I gave her every eighth hour a Dose of the spirits of *Harts-horn* in a spoonful of the following *Julup*: Take of the water of *Penny-royal*, of *Walnuts*, and *black Cherries* each four Ounces, of *Hysterical water* two Ounces, of the Syrrup of *Clove-gilliflowers* an Ounce and a half, of *Castor* tied in a little knot, and hanged in the middle of the glass half a Dram, of the Powder of Pearls one Scruple, mingle it. I caused with success a *vificatorie* to be put behind the Ears, and a *Cataplasm* of the leaves of *Rue* and *Cuccoe-pint*, with the *Roots of Bryony*, *Bay-salt*, and *black soap*, to be laid to the soals of her feet. Sometimes I gave her in the evening in a little draught of the prescribed julup, half an ounce of *Diacodium*, to which succeeded a moderate sleep, without the wonted Convulsions following: which kind of effects from opiats exhibited in the like case, I have often experimented: for the quenching her thirst I gave her a *Ptisan*, with diuretick Ingredients boiled in it: by the use of these, she was very much eased, in a short time. But what proved a great benefit to her, was, that an Imposthume in her ear, breaking of its own accord, poured forth, at first a yellow matter, and afterwards for many days, a great plenty of thin *Ichor* or *Excrement*, by which Evacuation, the Convulsions of the *Viscera* and *Præcordia* wholly ceasing, the disease was perfectly cured.

As to the Reason of the aforesaid sickness, without doubt, it seems, that those Distempers were excited by the serous colluvies, laid up within the bounds of the Head: for the translation of that humor into the head, brought at first both the Disease, and the Secretion or flowing of it out, thorow the Emunctuaries of the ear, took away all the Symptoms: Besides, when the morbifick matter had brought in to the spirits, planted about the beginnings of the nerves, a disposition somewhat explosive, they, though being struck as it were with madness, they were continually troubled, yet so long as leaping back towards the brain, they obtained a space, in which they might be more freely expanded or stretched forth, they did indeed only more vehemently exercise the Phantasie, and without farther trouble did only cause watchings. But when by

sleep

sleep sometimes creeping upon her, the excursion of the unquiet Spirits were restrained towards the Brain, (which indeed necessarily happens, when we sleep, the nervous Liquor within the pores of the brain, at that time being more plentifully admitted) they tumultuarily rushing upon the heads of the wandring pair, and intercostal Nerves, troubled the whole *series* of Spirits, flowing within the passages of those Nerves, and so caused the aforesaid Convulsions, about the *Præcordia*, *Viscera*, and muscles of the throat. I have known many both Men and Women sick after this manner, who when they have been troubled with an headach, an heavinesse of the hinder part of the head, or a *Vertigo*, have while they slept, felt forthwith in their *Præcordia*, or *Viscera*, or in both together, perturbations as it were Convulsive; which indeed happens from the bending downward of the tumultuating Spirits, being reflected from the brain, upon the beginnings of the Nerves: But that the use of opiats, brought a pleasing sleep to this sick person, without the wonted Convulsions, following, the reason was, because the animal spirits, as unquiet and furious as they were, yet by the Intanglement of the Narcotick Particles, they were bound as it were in Chains, that afterwards, without any resistance they were overcome by sleep. I have indeed very often happily cured, most grievous fits of Convulsions, both Asthmatical, and as it were Hysterical, by administring Opiates.

An honest woman M. G. of 67. years of Age, yet of a florid countenance, and fat in body, when she had been a while obnoxious at first to a swelling of the face, and very grievous fits of the headach, she fell through the great cold of the winter, into a very troublesome *Vertigo*, with a trembling of the heart, a fainting away of the Spirits, and a frequent striving to vomit: being layed in her bed, if she opened her eyes, or turned her from one side to another, she was presently troubled with a notable gidiness, or swimming in the head, with swooning and effectless vomiting. Visiting this woman, I doubted not, but that the cause of her sickness was, the Convulsive matter, being translated from the exterior region of the head, to the most inward recesses of the *Encephalon*, by whose inspiration or heterogeneous *Copula*, the animal spirits being touched while they leaped forth inordinately towards the brain, they excited the vertiginous Distemper, and while they rushed tumultuarily upon the heads of the nerves, the Scotomie, disorder of the *Præcordia*, and endeavouring to vomit. A large Vesicatory or blistering Plaister, being applied to the nape of the neck, and behind her Ears, Clisters daily administred, also the use of *Spirits of harts-horn* frequently, and of a Cephalick Julup, cured her within a few days. 2. *Observation.*

A noted man about 33. years of Age, when he had been for a long time subject to a Cough, with great and thick spitting, besides having the pores of his skin very open, he was wont to sweat continually, and every night to be wet with it: about the beginning of the spring, he perceived those usual evacuations to happen more sparingly; in the mean time, he complained of a fulnes of his hands and feet, and as it were a certain swelling or puffing up, so that he feared a dropsie was coming upon him; besides he was troubled in his head, with a giddiness and frequent *Vertigo*: A little after, this evil increasing, light contractions, and sudden Convulsions, were ordinarily excited about his Lips, and other parts of the mouth and face; also presently after (the morbific matter as it should seem, flowing upon the beginnings of the wandring pair and intercostal nerves) he was afflicted with the trembling, and leaping of the heart, with frequent fainting away of the vital spirits, as if a *Leipothemy* or swooning was falling upon him. 3. *Observation.*

I know that very many ascribe these Convulsive passions, so grievously infesting the *Præcordia*, to the vapours rising from the spleen: but it seems much more reasonable to deduce them from the Convulsive matter laid up within the brain, and rushing upon the beginning of the Nerves; because a shifting or translation of some excrements, from some other parts, to the head, goes before, and that it is so laid up, within the compass or bounds of the *Encephalon*, the almost continual vertiginous distemper, and the Convulsions of the parts of the mouth and face, testifie it plainly: wherefore I thought good to prescribe to this man Remedies according to the method hereafter shown.

I might be able here to propose many observations of this nature, in whom the morbific matter, subsisting near the beginnings of the nerves, stir up light Spasms or Convulsions only of the *Viscera* or members, with a *Vertigo*. But because a portion of this matter, descending from the head, enters more deeply the pipes of the Nerves, and so strows the tinder or enkindling of explosive seed, as it were gunpowder, about their middle and ultimate processes and enfoldings, it will be to the purpose to add some examples of this kind.

A certain young maid E. L. tall and handsome, sprung from sound parents, and her self (as far as might be perceived) originally healthful, after she had served a master long sick, being a long time, and almost continually with him, and was forced to watch whole nights very often, and also at other times, so that she never slept but short and interrup- 4. *Observation.*

terrupted naps; she at length begun to complain of an heavinesse in her head, and a frequent *Vertigo*: within a little time after, the distemper growing worse, she felt tremblings in her whole body, with a light shaking of her members, which came at certain times, tho wandring and uncertain: afterwards she suffered fits plainly Convulsive, and those horrid, and often Infesting: a little before the approach of the disease, she was afflicted with a short *Scotomie* or swimming in her head, by and by she felt a streightnesse, and great oppression of her Breast, whereby all her *Precordia* were drawn together: then presently gnashing her teeth, and giving a great groan, she was wont to fall to the ground, in the mean time she was sensible, but labouring with the great oppression of her heart, till that constriction of her breast was loosned, she was not able by any means to rise; afterwards, when the fit was past, she was disturbed a good while, with a great palpitation of the Heart, an heavinesse of the senses, and a great debility of the animal function. After that this Sick maid had lived subject to these kind of fits, being very often repeated, for about 14. months, she at last became Epileptical, that as often as the assault of the evil rerurned being flung prostrate on the Earth, she was taken with the Insensibility or amazednesse of Spirits, with the foaming at the mouth, and other peculiar symptoms of the falling sickness. Neither did this distemper stay here, but ere the space of a year was elapsed, it degenerated into madness, that at last the sick maid, having lost the use of her Reason, grew sometimes mad with fury, and sometimes was plainly stupid and foolish.

The reason of the aforesaid Case.

It is plain from the beginning, progress, and often *metamorphosis* of this Disease, that it at first had its cause and seat in the head, near the beginning of the Nerves, and from thence did daily unfold more largely its bounds, both into the brain, and nervous System; for from the beginning, the morbific matter consisting near the beginnings of the nerves, caused only lighter Spasms or Convulsions of the *Viscera* and members, and shakings, with the *Vertigo*; afterwards a portion of it being slidden into the pneumonic nerves, and their foldings, produced most grievous Convulsions of the *Præcordia*, *Diaphragma*, and *Ventricle*; and also another portion of the same matter invading the brain, and its marrow, caused the Insensibility or Amazedness, and so the fits of the Falling-sickness; and at length, the texture of the spirits being wholly vitiated, and their *Latex* being degenerated into a most sharp, and as it were Stygian Liquor, the Convulsive distempers passed into madness.

Therefore, as to the particular reasons, both of the disease, and symptoms, it seems, that the aforesaid Virgin, by her sedentary Life, (she being deprived altogether of the exercise of the body, and the use of a more free air) but chiefly by her nightly watchings, and being frequently interrupted of her sleep, she had contracted a vitious disposition of the blood and humours, and also a praved and weak constitution of the brain, and Nervous stock (to which may be added, that she did perpetually attend on a Master, sick of most grievous distempers of Convulsions, and by that means had received perchance some contagion, or convulsive infection: and first of all indeed, the Heterogeneous Particles being poured forth, together with the nervous juice, into the brain and Cerebel, and there cleaving to the spirits, as it were skirmished with the preliminarie scotomie, and vertigenous distemper; then the convulsive matter, setling upon the beginnings of the wandring pair, and intercostal Nerves, and the spinal marrow, brought in, with the *Vertigo*, the leaping of the *Viscera* and Muscles, and their lighter shakings: Afterwards when entring more deeply the pipes of the Nerves, it was carried into the Cervical, and Cardiac, and perhaps intercostal, and other unfoldings, and embued the spirits, performing the office of respiration, and the pulse, with an explosive *Copula*; they being brought into explosions at every turn together with their superiors, inhabiting the nervous origine, by reason of fulness, or because of irritation, excited most horrid Convulsions of the respective parts: But the fit growing strong, from the pneumonic or breathing Nerves being strictly bound, the sudden inordinate systole of the Thorax was stirred up; then presently the *Diaphragma* being suddenly and vehemently drawn back, the obstreperous ejaculation did succeed: Further, when by reason of the systole of the Thorax, being sometime continued, the blood being hindred, that it could not move, it *stagnated* altogether in the *Præcordia*, therefore, during the fit, that great oppression of the heart, with want of speech and motion afflicted the sick Maid: But in the mean time, while as yet the region of the brain remained free and clear from the explosions of the spirits, the sick party remained in her senses, or memory: but afterwards when the Convulsive matter being daily increased, it was unfolded in the middle or marrowy parts of the debilitated and broken brain, to the former passions; about the *Præcordia*, came also the insensibility and amazedness of spirits, then the Epilepsie, and lastly madness, for the reasons before recited. Many Medicines, and of various kinds, being prescribed to this sick Maid, by many, both Physicians and Empericks,

ricks, but confuſedly, and with an uncertain method, being preſently changed, did her no good.

A certain fair woman, well coloured, and well fleſh'd, from a ſetled grief, fell into a ſickly diſpoſition; about noon, and the evening, for the moſt part ſhe was pretty well, but in the morning when ſhe had ſleep enough, and often indulged it too much, till ſhe became very ſomnolent and heavy: being thoroughly awakened, preſently ſhe was wont to complain of a heavineſs, and as it were a ſtupidneſs in her whole head, with a *Vertigo* at every motion, or ſtirring about of her head; a little after ſhe conſtantly expected a Convulſive Fit, or the inſenſible amazedneſs of the ſpirits, and ſometimes this, ſometimes that, was wont to infeſt her: for that after the *Vertigo*, as it were a *prævious Vellication*, for the moſt part, ſhe felt in her ventricle, and left ſide, an heavy or weighty pain running up and down here and there; hence belching, a ſtriving to vomit, eruptions of blaſts, alſo wonderful diſtentions of the abdomen, and hypochondria, did follow, and ſometimes for many hours, did miſerably exerciſe this Woman; but ſometimes theſe Symptoms hapned to be wanting, and then the diſtemper more cruelly afflicted her brain: for falling into frequent inſenſible fits, ſhe was wont to continue a great while immovable, and with her eyes ſhut, without ſenſe or unſtanding; and when her ſervants had moved her by rubbings, and with the ſume of Tobacco, ſhe came by and by to her ſelf, but preſently again ſhe fell into the like inſenſibility, and ſo for four or five times, before ſhe could perfectly recover her ſelf, and be without expecting to fall into theſe fits again: At le gth the Tragedy being acted, ſhe remained however affected with an heavineſs and torpor of head, in ſome meaſure: but about noon, all the clouds being diſcuſſed, ſhe was wont to obtain a fair, and ſerene diſpoſition of her whole head, until the next morning, the ſame Symptoms would return again. 1. *Obſervation.*

Who ſhall rightly weigh theſe Symptoms, need not ſuppoſe them vapours, ariſing from the Womb or Spleen, and in thoſe ſeek for the morbific cauſe in vain: which truly may more certainly be placed in the head it ſelf: for it ſeems, that by reaſon of a great ſadneſs (which happens often to women) at the beginning, a great debility, together with a vitious taint, was impreſſed on her brain; ſo indeed that the animal ſpirits derived to the brain and Cerebel, brought with them heterogeneous particles of a mixt kind, *viz.* Partly narcotick or ſtupifying, and partly exploſive or ruſhing forth: which kind of Copula, when they had more plentifully conceived, through ſleep they were ſtirred up to the ſhaking of it off, by mere fulneſs: as ſoon therefore, as the woman was awakened, the ſame ſpirits being moved, either a bending downward being made below, they were depreſſed upon the beginnings of the Nerves, and there being exploſed, they excited Convulſions of the *viſcera*; or leaping back towards the middle of the brain, and being there ſtruck off, they brought in thoſe frequent and terrible Inſenſibilities. In truth, this diſtemper was ſomewhat akin to the Epilepſie, but that the morbific matter was not as yet ſtayed within the regal palace of the brain, or its middle part, ſo that there it might infect the ſpirits within the fountains; but yet the ſame heterogeneous Copula, did cleave more ſtrictly to them, diſſociated or disjoined below, and dividing themſelves into various and leſſer rivolets according to the beginning of the nerves. In the mean time, the ſpirits, whereby they might ſhake off that matter, being often exploſed, cauſed the ſtupor and inſenſibility, but bending to ſome other place, they ruſhed upon the beginnings of the nerves, for that reaſon cauſed thoſe Spaſms or Convulſions of the *viſcera*: but that the fits come only in the morning after a plentiful ſleep, the reaſon was becauſe the heterogeneous Copula of the ſpirits, coming to them with the nervous juice, was at that time gathered together to a fit fulneſs for exploſions, which being then wholly ſhaken off, the ſick perſon remained therefore all the reſt of the day free from the diſtempers, till the next day, when the night Sleep had brought to the head, a new ſupplement of morbific matter, the like fit returned in the morning, which perhaps, as the Sleep had been ſhorter or longer, was moved now within the brain, now near the nervous origine.

An Obſervation of a diſtemper as it were hyſterical in a man.

But it may be obſerved, that Convulſions have ariſen from the nervous origine, being chiefly affected, not only in the female ſex, as the weaker and more liable, but ſometimes theſe kind of diſtempers have been excited in men from the like procatartick cauſe. Some years ſince, being haſtily ſent for from a ſtranger, who lodged in this City, at firſt ſight, I ſuſpected that he was poſſeſſed, and believed that he had more need of Exorciſms, than of Medicines. He was about Forty years old, who had now for about three years, at certain ſet times of the year, been wont to be troubled with convulſive Motions; whilſt he by chance lodged here for a few days about his occaſions, by reaſon of a great ſadneſs, he had a fit of his ſickneſs greater than uſual: He was wont for two or three days beforehand ro feel the coming of his diſeaſe; to wit, from a great

commotion within the forepart of the head, almoſt a continual *Vertigo*, and frequent dimneſs of his eyes: But the fit coming on him, at firſt his eyes were variouſly roled about, and inverted, then a certain bulk, like a living animal, was ſeen to creep from the bottom of his belly upwards, towards his heart and breaſt, and from thence to his head: I my ſelf preſſing his belly with my hand, felt very plainly this kind of motion, and as long as I hindred this round thing from aſcending with both my hands, and all my ſtrength, he found himſelf indifferently well; but as ſoon as this ſwelling creeping upwards by degrees, had reached the head, preſently the members of the whole body were cruelly pulled together, that he would daſh himſelf againſt the walls or poſts, as if poſſeſt by an evil ſpirit; He could hardly be held, and reſtrained by four ſtrong men with all their force, but that he would leap from them, and fling out his arms, feet, and head here and there, with divers manners of motions: when he ceaſed from leaping forth, or ſtrugling, his Members would be ſtrongly extended, and his muſcles ſtiff, as if troubled with the Cramp or ſtiff extenſion: ſuch a fit would laſt about a quarter of an hour, then coming to himſelf, he would talk ſoberly, and walk about in his Chamber; he knew what he had ſuffered, and asked pardon of the ſtanders by; preſently after he began to draw his eyes inward, and ſwiftly to role them about: then preſently the convulſive diſtemper returning, acted the like Tragedy as before: and after this manner, he would have five or ſix of theſe kind of convulſive fits, within three hours ſpace. In the midſt of one of theſe fits, a vein in his Arm being opened, and a large orifice made, the blood flowed out ſlowly, and was ſeen preſently to be congealed: and ſo indeed, that being received into the diſh, it did not flow about, after the manner of Liquors, with a plain and equal *ſuperficies*, but like melted ſewet, dropped into a cold Veſſel, one drop being heaped upon another, it grew to a heap.

The reaſon of the aforeſaid Caſe.

If this ſtrange diſtemper had hapned to a Woman, it would preſently have been ſaid that it was the Mother, or Hyſterical, and the cauſe of it would have been laid on the fault of the Womb; eſpecially, for that the aſcent of ſomething, like a bulk, began the fit, from the bottom of the belly: But when this common ſolution, which moſt often is the mere ſubterfuge of Ignorance, cannot be admitted in this caſe, it ſeems moſt congruous to reaſon, to refer all theſe Symptoms to the evil affections of the brain and nervous Stock. For truly it may be plainly gathered, that the cauſe of the diſeaſe, did lie hid in the head it ſelf, by the Symptoms preceding the fit, which did denote a very great agitaiton of the ſpirits within the head; that inflation of the brain, and heavy ſwimmings, which conſtantly came juſt as the fit was coming upon him, the turnings of the eyes manifeſtly argue, that heterogeneous and exploſive particles, did adhere to the ſpirits dwelling within the *Encephalon*, near to the beginnings of the Nerves. So that this caſe, comes near to the nature of the Epilepſie, excepting that the ſpirits within the middle of the brain, did not admit an heterogeneous Copula, nor being exploſed in another place, did they tumultuouſly break forth there; for during the fit, the ſick Perſon was ſtill in his ſenſes, or had the uſe of his memory: But the morbific matter, being more plentifully laip up in the head, when from thence it was ſlid, more deeply into the pipes, both of the Interior and Exterior Nerves, it had placed mines of Exploſive ſeeds, very diffuſive in the *viſcera*, both of the lower and middle belly, and alſo in the exterior members, ſo that when the animal ſpirits began to be exploded, near the beginnings of the nerves, preſently from thence others inhabiting the meſenteric enfoldings, and then others in the other nervous enfoldings, interjected from the outmoſt bound, even to the head, being exploſed in order, did even continue the Convulſions, from one part to another, until they came to the head it ſelf: but preſently the exploſion being tranſlated from thence, to the ſpirits dwelling in the ſpinal marrow and Appending Nerves, the moſt ſtrong Convulſions of the muſcles and members of the whole body followed: But that, that aſcent, as it were of bulk, or ſubſtance which very often was perceived in the lower belly, about the beginning of the Convulſions, proceeding from the ſpirits, within the meſenteric enfoldings, being brought into exploſions, ſhall be more largely declared anon, when we come to treat of hyſterick paſſions.

In the mean time if it be asked for what reaſon that the convulſive paroxyſm, beginning in the part of the head, near the beginnings of the Nerves, preſently the ſpirits dwelling in the outmoſt parts (as many as are prediſpoſed for that Symptom) enter into exploſions, and ſo transfer the convulſive Diſtemper, being there fully raiſed upwards, (for it is for the moſt part ſo, whether the entrance of the diſeaſe begins in the bottom of the belly, or about the middle of the abdomen, the *Hypochondria* or *Præcordia*, for that the Convulſion is wont to creep by degres from thoſe places towards the head:) I ſay, for the ſolution of this, theſe two conſiderations are offer'd, to wit, in the firſt place we conſider, that when ſome whole *ſeries* of ſpirits is diſturbed, thoſe who

Wherefore the Convulſions begin from the extremities of the Nerves.

who reſide in the extreameſt bounds are firſt deſtituted of their original Influence; wherefore they, before others, grow tumultuous, and begin to grow irregular; hence it is, when the Nerve of the arm or thigh, is ſtrained hard, by leaning on it, that the wonted Influence is hindred, that a numneſs, with a ſenſe of pricking or tingling, is firſt felt in the fingers or toes; from whence by degrees, it creeps upwards towards the places affected. Secondly, the other is, and rather the reaſon of this diſtemper, to wit, that the ſpirits being ready for exploſions, when they are contained within the nervous pipes, one or more, as ſo many diſtinct little Tubes, they require a ſufficient ample ſpace, in which they may be able very much, and indeed ſucceſſively to be rarified and expanded, which thing becauſe it cannot be eaſily performed within the Trunks of the Nerves, from the beginning towards the end, therefore while the Spirits, about the nervous origine, being firſt ſtruck off, leap back towards the *Encephaleon*, for that cauſe they ſtir up the vertigo: the more open exploſion of the ſpirits, for the moſt part, begins about the inferior paſſages of the nerves, or at their extremities, where the trunk of the nerve is either dilated into more ample foldings, or terminated in more *fibres* largely diſperſed abroad; then thoſe Spirits being exploded, there is room made preſently for others ſucceeding in order, whereby in like manner they may be exploded: Hence we may obſerve whilſt the exterior Spirits are exploded, if a ligature or hard compreſſion being made, the ſucceſſion of others into the ſame ſpace or their progreſs toward the exterior parts be intercepted, the Convulſion is wont to be hindred, that it cannot aſcend upwards, wherefore when a numbneſs (as medical Hiſtories teſtifie) being ariſen from the fartheſt end of the finger or toe, creeps to the ſuperior parts, with a tingling, or like a cold air, and at length reaching the brain, cauſes moſt horrid Convulſions; if by and by after the motion is begun, the Arm or Thigh be ſtrongly tied, the Spaſm or Convulſion not being able to get over the bound place, is hindred from coming to the head; yea, it is uſual for hiſterical women, as ſoon as the ſwelling of the belly, or the aſcent of the bulk in the abdomen is firſt perceived, to gird ſtrongly their waiſts with Swathing bands, and ſo oftentimes they prevent the *Præcordia*, and the region of the brain, from being diſturbed by that ſame Convulſive Fit.

Wherefore the blood is ſoon congealed in Convulſive diſtempers.

But that the blood being let out in the midſt of the fit, was ſo ſoon congealed, indeed it very ordinarily happens to be ſo in Convulſive and Apoplectical Diſtempers, as the moſt learned *Heighmore* hath firſt noted out of *Hendochius*: But that ſome from hence contend, that convulſions rely altogether upon the thickneſs of the blood, and ſtagnation, its motion being hindred, cannot be granted: becauſe the blood taken from thoſe who are ſubject to convulſions, a little before the fit, is dilated with *ſerum*, and fluid enough: wherefore we may lawfully think, that the congelation is cauſed by the *paroxſm* it ſelf, becauſe in Convulſive motions, and immoderate contractions of the Nerves, and *Viſcera*, the interflowing blood by the exhalations of its ſpirit and *ſerum*, is ſomewhat looſened in its mixtion, and therefore in ſome ſort coagulated; like as when milk, by reaſon of too much agitation and ſeparation of the parts one from another, grows into butter; wherefore this kind of Coagulation of the blood, ſeems rather to be the effect, than the cauſe of the Convulſions.

The Curatory Method.

AS to the cure of theſe kind of Convulſive Diſtempers, which in women, or men, proceed from the morbific cauſe lying upon the beginnings of the Nerves. The firſt indication will be, to draw away the tinder or inkindling of the diſeaſe, *viz.* to hinder that the blood may not affix on the head, the heterogeneous particles, either begot in it ſelf, or received elſwhere from the *Viſcera*. For this purpoſe an evacuation both by catharticks, and blood-letting, unleſs ſomething contradict, is wont to be beneficially preſcribed.

Emeticks.

Vomiting moſt often brings help, wherefore Emeticks of the Infuſion of *Crocus metallorum*, or of the *Salt of Vitriol*, or *wine of ſquils*, is to be taken at the beginning. Then almoſt the next day, the taking away of Blood, either by *phlebotomy* in the Arm, or by Leeches in the Sedal veins, is to be performed; then afterwards a gentle purge of *pills*, or ſolutive Apozems, is to be ordained and timely repeated.

Purges.

Take of the *pills* of the *Amber of Crato*, or of the *Tartar of Bontius* ʒ ii. of the *Reſine of Jalap*, gr. xvi. of *Caſtor* ϑ i. of the *oyl of Roſemary* or *Amber*, ϑ ß. of *gumm-Ammoniac* diſſolved in hyſterical water, what will ſuffice to make 16. pills. Let 4. of them be taken every ſixth or ſeventh day.

Take of the *Roots of Polypodia* of the *Oak*, of *ſharp pointed-docks* prepared, *of Chervil*, each 3 vi. of the *male Pæony*, 3 iii. of the leaves of *Betony*, *Germander*, *Chamipits*, *Vervine*, the *male Betony*, each i. handful, of the ſeeds of *Cardamums*, and *burdock* each 3 iii. let them be boiled in 4. pints of Spring water, till half be conſumed: Let it be ſtrained into a matrace, to which put of the leaves of the beſt *Senna*, one ounce, of *Rhubarb*, 3 vi. of *Turbith* gummed half an ounce, of *Epithimum*, of *yellow-Sanders*, each 3 ii. of the *Salt* of *worm wood*, and *Scurvy-graſs*, each 3 i. the yellow rine of the *Orange* 3 ii. let them digeſt cloſe ſhut, in hot ſand for 12 hours, let the ſtraining be kept for uſe, ſweeten it (if there be need) with what will ſuffice, of the *Auguſtan* Syrrop, or of *Succory* with *Rhubarb*. The Doſe ſix ounces, once or twice in a week.

Remedies for a more hot temperament.

Every day, in which purges are not taken, Remedies ſtrengthning the brain, and alſo the animal ſpirits; for the taking away the Heterogeneous *Copula*, or for the hindring them from running into exploſions, are to be adminiſtred, which indeed ought to be preſcribed and choſen according to the conſtitution and habit of the Body, and temperament of the ſick; for too lean bodies, and ſuch as being indued with a more hot blood, Medicines leſs hot, and which do not trouble the blood above meaſure, ought to be given: On the contrary, for phlegmatick and fat people, whoſe Urine is thin and watery, and whoſe blood is circulated more heavily, and *Viſcera's* ſtuffed, more hot Remedies, and notably apt to ferment the humors, are deſigned. In the former caſe let it be preſcribed after this manner.

Coroborating medicines and ſpecificks.

Take of the *Conſerve* of the *Flowers of Betony*, *Tamarisk*, the *Male Pæony*, each two Ounces, of the *Species* of *Diamargerit frigida* a Dram and a half, of the *Powder* of the *Root* of *Pæony*, and of the *Seeds* of the ſame, each one Dram, of *red Coral* prepared two Drams, of *Vitriol of Steel* two Scruples, of the *Salt of Wormwood* two Drams, with what will ſuffice of the juice of *Oranges*, make an *Electuary*, take of it twice or thrice in a day, drinking after it a little draught of the Julup hereafter preſcribed.

Powders.

Take of *Coral* red, with the juice of *Oranges*, beaten together in a Glaſs, or Marble mortar, and dried, half an Ounce, of the Powder of *Miſſletoe* of the *Oak*, of the root of the *Male Pæony* two Drams, of perled Sugar three Drams, make a Powder: the Doſe from a Dram to half a Dram, twice or thrice in a day.

Take of the *Species* of *Diamargarit frigida* two Drams, of the *Salt of Wormwood* three Drams, of the root of *Cocoe-pint* powdered one Dram, mix them, make a Powder, let it be divided into xx parts; take a Doſe in the morning, and at four in the afternoon.

Diſtilled waters and Julups.

Take of the *Roots of Butterbur* one Ounce; doſe half a Dram to a Dram twice in a day.

Take of the *Leaves of Burdock* and *Cocoepint* each ſix handfuls, let them be cut and mixed together, and ſo Diſtilled. The Doſe two Drams to three, twice or thrice a day, after a Doſe of *Electuary* or *Powder*.

Take of this water diſtilled two pints, of our *ſteel* prepared two drams, mix them in a Vial, let it be taken after the ſame manner.

Take of the ſimple water of *Walnuts*, and of *black Cherries* each half a pint, of *Snales* three Drams, of the Syrrup of the flowers of the *Male Pæony* two Ounces: the Doſe an Ounce and a half to two, after the ſame manner.

Take of the *ſhavings* of *Ivory* and *Harts-horn*, each three Drams, of the *roots of Chervil*, *Burdock*, *Valerian*, each half an Ounce, of the leaves of *Betony*, *Chamepits*, *Harts-tongue*, the tops of *Tamarisk*, each one handful, of the barks of *Tamarisk*, and of the *woody Nightſhade*, each half an Ounce, let them be boiled in two quarts of ſpring water, to the conſumption of the third part; add to it of *white-wine* eight Ounces, ſtrain it into a Pitcher, to which put of the leaves of *Brook-lime*, and *Cardamine*, each one handful, make an infuſion warm, and cloſe for four hours: Let the colature be kept cloſe in Glaſſes. The Doſe ſix Ounces twice in a day; after a Doſe of ſome ſolid Medicine, ſometimes ſuch an *Apozeme* may be mixed with two Drams of our *ſteel*, and taken in the ſame manner.

In the Summer time, the uſe of *Spaw-waters* is convenient; and for want of them, our Artificial ones may be taken.

Remedies in a more cold temperament. Electuaries.

If that for the reaſons above-recited, more hot Medicines are to be preſcribed, you may proceed according to the following method.

Take of the *Conſerves of Roſemary*, of the *yellow* of *Oranges* and *Lemmons*, each two Ounces, of *Lignum-aloes*, of *yellow-ſanders*, of the roots of *Snake-weed*, *Contrayerva*, *Angelica*, *Cocoepint*, each one Dram, of the *Vitriol of ſteel* (or of *ſteel* prepared) four Scruples, of the *Salt of Wormwood* and *Scurvey-graſs*, each one Dram, with what will ſuffice of *candied Walnuts*, make an Electuary; let it be taken twice in a day, to the quantity of a Nutmeg, drinking after it a doſe of appropriate Liquor.

Take

Take of the *Roots of Male Pæony, Angellica,* and red *Coral* prepared, each two drams, *Tablets.* of *Sugar* diſſolved in water of *Snales,* boiled to the conſiſtency of Tablets, ſix Ounces, of the *Oil of Amber* lightly rectified half a dram, make a ſufficient quantity of *Lozenges,* each weighing about half a dram, take one or two twice or thrice a day, drinking after it a doſe of proper Liquor.

Take of the *Roots* of *Virginian Snake-weed, Contrayerva, Valerian,* each two drams, *Pills.* of red *Coral,* and prepared Pearl, each one dram, of *winteran Bark,* and of the *root of Cretian Dittany,* each one dram, of the *Vitriol of ſteel,* and *Salt of Wormwood,* each one dram and a half, of the extract of *Centaury* two drams, of *Ammoniacum* diſſolved in *Hyſterical* water what will ſuffice, to make a pillulary maſs: of which take four Pills in the Morning, and at four in the Afternoon.

Take of the *Spirits of harts-horn,* or *Sut,* or *humane Blood,* or of *Sal ammoniack,* what *Spirits.* will ſuffice, take of them from 10. to 12. drops, morning and evening, in a ſpoonful of Julap, drinking a little draught of the ſame after it.

Take of the *Leaves of Betony, Vervine, Sage, Lady-ſmocks, Cuccoepint, Burdock,* each *Diſtilled wa-* two handfulls, of *green wallnuts,* number 20. the *rinds* of ſix *Oranges,* and of 4 *Lemons,* *ters.* of *Cardamus,* and *Cubebs,* each one ounce, being cut and bruiſed, pour on them of whey made of *Cider* or *white whine,* ſix pints, let them be diſtilled according to Art. The doſe two ounces or three twice in a day, after a doſe of a ſolid medicine. Add to i. quart of this liquor ii. drams of our *Steel.*

Take of the *water of Snails,* and of *earth-worms,* each ſix ounces, *walnuts ſimple* four ounces, of *Radiſh* compound two ounces, of *white ſugar* ii. ounces make a Julap. The doſe 4. or 6. ſpoonfulls, twice in a day, after a doſe of a ſolid medicine.

Take of *millipedes* or *cheſilogs,* cleanſed, i pint; of *Cloves* cut, half an ounce, put to them i quart of *white-wine,* let them be diſtilled in a glaſs-cucurbit. The doſe one ounce to an ounce and a half, twice in a day.

For poor people, medicines eaſie to be prepared, may be preſcribed after this manner.

Take of the *Conſerves* of the *Leaves of Rue,* made with an equal part of *ſugar,* ſix ounces; take of it the quantity of a *nutmeg,* twice in a day, drinking after it of the decoction of the *Seeds* and *Roots of Burdock,* in *whey* or *poſſet-drink* made of *whitewine.*

Or there may be prepared a Conſerve of the *leaves* of the *Tree of Life,* with an equal part of Sugar: doſe ʒ ß. to ʒ i. twice in a day.

Take of *millipeds* prepared ʒ iii, of *ameos ſeeds* ʒ i. make a powder, divide it into 10. parts, take a doſe twice in a day, or 12 *Sows* or *Woodlice* bruiſed, and whitewine put to them, let the juice be wrung out, make a draught, let it be taken twice a day.

In the mean time, while theſe Medicines are taken inwardly, it is ſometimes convenient to raiſe bliſters, with Veſicatories, in the nape of the neck, and behind the ears; for ſo the ſerous and ſharp humors, are very much brought away from the head: beſides ſneezing powders, and ſuch as purge Rheume from the head, often give ſignal help. The taking away of blood from the ſedal veins, or the foot, ought ſometimes to be itterated; yea, and the Diſtemper urging, Plaiſters or Cataplaſms, are profitably applied to the ſoles of the feet. It is alſo beneficial to apply drawing medicines about the calves and thighs.

CHAPTER VI.

Of Convulſive Motions, whoſe cauſe ſubſiſts about the extremities of the Nerves, or within the nervous foldings.

SOmetimes Convulſive Diſtempers do ariſe, without any fault in the Head, by the irritation and exploſion of the ſpirits, remaining about the extremities of the nerves, which plainly appears, becauſe when medicines haul ſharply the Ventricles or Inteſtines, or worms gnaw them, there do not only follow Convulſions in thoſe parts, but beſides convulſive motions do ſometimes torment (or are retorted on) the members, and outward Limbs: for indeed, as we have ſhown elſewhere, when the ſenſe of a very grievons Trouble torments any part, and from that is communicated to the chief ſenſorie, preſently from thence an involuntary and irregular motion, is wont to be reflected on the ſpirits in that place irritated; and that not only by the ſame nerves, to which the ſence of the pain was carried, but ſometimes alſo the Convulſion is reciprocated by others, either neighbouring, or altogether extraneous: So the Stone being fixed in the

Ure

Ureters, and irritating very much its nervous *fibres*, excites convulsive motions, not only in the distempered Vessels, but almost in all the *Viscera* of the Abdomen: So that the Urine being suppressed, Torments diffused here and there, and very often horrid Vomitings follow. Wherefore, 'tis not at all to be doubted, but that both diseases, and some Convulsive Symptoms, are very often induced, by reason of an outward hurt, brought to the Tops of the nerves, terminating within the membranes, muscles, or *Viscera*: yea in the hysterical, *hypochondriaca*, and certain other passions, if at any time Convulsive motions are excited, in the hurt head by the fault of the womb, spleen, or other inward; verily they arise by this only means, to wit, by the Trouble of the rest of the parts, being translated this way through the Nerves, (but in no wise by the Vapours) to the brain, and are propagated all about into various Regions of the Body.

Convulsions begin from the ends of the Nerves, both by reason of irritation.

But it should here be noted, that altho the evident solitary cause, forasmuch as it is strong and vehement, may sometimes induce Convulsions of it self, and without a previous disposition: beacuse indeed the Animal Spirits irritated, beyond measure, begin greater, and more than ordinary explosions, as in overgreat purging, and Vomiting, and the fits of the Collick, and Stone, is ordinarily wont to happen; yet in many other convulsive Distempers, whose fits are often and habitual, besides the irritation made, about the extremities of the nerves, which serves for the most part for the evident cause, also a certain more remote cause is present, to whose efficacy the assault of the disease is chiefly beholden; to wit, when convulsive motions are wont to be excited, and at every turn repeated, by the fault of the Spleen, Womb, or other private part, it may be suspected, that the animal Spirits, of the *Fibres* in the distempered part, and those disposed in its neighbouring parts, had first contracted an heterogeneous, explosive *Copula*, by which being filled, to a running over, they were provoked, by a light occasion, to convulsive explosions: Then, those being first begun, about the extremities of the nerves, creep upwards by the passage of the same nerves, and are often carried to the same nervous origine, and sometimes beyond, to the middle of the brain: from whence, lastly, being reflected on the Nervous stock, they also secondarily cause the convulsions of the members and limbs: But after the brain, and a superior portion of the nervous system, are wont to suffer, and be affected often, by the convulsions below excited, the spirits inhabiting those parts, also begin to be themselves adulterated at length, and to admit an heterogeneous and explosive *Copula*, and so to acquire in part, a procatartick cause; hence at length a Convulsive procatarxis, or more remote cause, becomes common to either end of the Trunk of the same nerves, and the animal spirits of one nerve, or more being evilly disposed, both at the head and tail, conceive explosions from either part, and deliver them presently to the other, as shall be more largely declared below, when we treat particularly of hysterical, and other; passions in the mean time, we will add some histories and observations of convulsions arising from the farther ends or extremities of the nerves.

And by reason of an explosive Copula.

1. *Observation.* A fine maid, about the 16th. year of her age, falling from her horse, and lighting upon a Stone, grievously hurt her left breast, from whence a Tumor arose, with pain, which Symptoms notwithstanding by the use of Medicines, at the beginning seemed to be mitigated, and to be indifferently well, for a long time after. Three years after, she having taken cold, and having observed but a bad course of dyet, all things began to be exasperated, the hurt part swelling into a bigger bulk, troubled her with an acute, and almost continual pain, that the sick Virgin, for the cruel torment, could take no rest for many days and nights, neither could she suffer the *glandula's* of her breast, being then made more tumid, to be either touched or handled; yea nor any noise, or shaking to be made in the Chamber.

When to this Tumour, about to degenerate into a Cancer, they had applied fomentations, and Cataplasms of *hemlock* and *mandraks*, and other stupifying and repercussing things, this gentlewoman began to suffer certain Convulsive affections infesting her very often: At first, as often as the pain in her breast did most cruelly torment her, she felt in that place, prickings, also convulsions, and contractions, running about here and there, then presently her *Ventricle* and *Hypchondria*, and often the whole *Abdomen*, were wont to be inflated, and very much distended, with an endeavour of belching and vomiting; by and by, the same distemper, being leasurely translated to the superior parts, excited Insensibility; to which shortly after, convulsive motions succeeded, in the whole Body, so strongly, that the sick party could scarce be held by three or four strong men.

These kind of fits, at first were wandring, and only occasionally excited: to wit, they would come, as often as the pain of her breast was strained, by some evident cause: Afterwards, these convulsions did more often infest her, and at last, they became habitual, and periodical, twice in a day, to wit, they were wont to come again constantly, at so many set hours after eating: And when after this manner, the sick Gentlewoman had been

been miſerably afflicted, for ſix moneths, at length, ſhe began to be moleſted with a vertiginous Diſtemper of her head, exerciſing her almoſt continually: for which evil when a fomentation of aromatick and cephalick herbs, had been a good while adminiſtred to her head, ſhe became better, as to the giddineſs; but then ſhe was perpetually infeſted with a quite new, and admirable Symptom, *viz.* an empty cough, without ſpitting, night and day, unleſs when ſhe was overwhelmed with ſleep: After this worthy Virgin, had tryed without much benefit, divers medicines and remedies, preſcribed by ſeveral Phyſitians, ſhe was at laſt helped by making uſe of the moſt temperate Bath, at the Bath; then being preſently married, after ſhe had conceived, and was brought to bed, ſhe by degrees grew well.

If the reaſons of the whole diſeaſe, and its accidents, be inquired into, without doubt the convulſive diſtemper was firſt of all excited from the tumor or pained place of the breaſt; the cauſe of which was partly the moſt ſharp ſenſe of pain, being impreſſed from its *fibres* and nervous parts, but partly by the heterogeneous Copula, being affixed on the ſpirits inhabiting thoſe *fibres* and Nerves; for truly, it may be ſuſpected, that the moſt ſharp humour impacted in the Tumor, which perhaps had in ſome ſort flowed thither by the paſſages of the Nerves, being repercuſſed by the uſe of Topicks, had entred the *Fibres* and Nervous filaments, or little ſtrings diſpoſed thorow the whole border or neighbourhood, and ſo the heterogeneous and exploſive Copula, had clove to the ſpirits; for the ſhaking off of which, as often as by pain they were excited, they entred into Convulſive exploſions, and together with them, other ſpirits flowing within the neighbouring Nerves, by conſent of the forms (as it often happens) were exploded after the ſame manner: Then the Convulſive Diſtemper, when it firſt had begun in the extremities of the Nerves, being continued thorow their paſſages, even to the head, was wont to cauſe the inſenſibleneſs; and from thence leaping back upon the whole *nervous ſyſtem*, the Convulſive motions of the Limbs and all the members: The fits, about the beginning of the ſickneſs, being excited after this manner, by reaſon of pain from the diſtemper'd part, were carried ſecondarily to the brain and its appendix: But afterwards, when the ſpirits inhabiting thoſe places, being often exploſed, by ſympathy, had ſo looſned, and weakned the pores of the containing parts, that there lay open a paſſage within the ſame, for all Heterogeneous Particles to enter, with the nervous juice, the Convulſive *procatarxis* or more remote cauſe alſo increaſed in the head; and the ſpirits inhabiting the *Encephalon*, being infected with an heterogeneous Copula, they themſelves begun the Convulſive fit, or at leaſt afforded the firſt inſtinct to its aſſault, which did return, for the moſt part, at ſuch ſet hours after eating, becauſe the morbific matter was carried in, together with the nervous juice, almoſt in an equal dimenſion: In truth, in ſuch caſes, where the Convulſion being general, doth poſſeſs almoſt all the parts of the whole *nervous ſyſtem* ſucceſſively, we may ſuſpect, that the animal ſpirits had contracted an heterogeneous and exploſive Copula, in the whole nervous ſtock, which, when it is ariſen, at the ſet time, to a fulneſs, incites the ſpirits themſelves at the appointed time, in like manner, to exploſions, and the ſame exploſion being begun ſomewhere, is propagated in order to all, after the manner of a fiery enkindling. *The reaſon of this.*

As to that empty cough, which ſucceeding the fomentation of the head, exerciſed this ſick perſon almoſt inceſſantly for many months; it ſeems, that this ſymptom ſhould depend altogether from the *nervous origine* being diſtemper'd, and not at all on the ſtuffing of the Lungs; for ſhe did not avoid any thing with the cough; and if at any time that force of coughing was violently reſtrained, preſently ſhe was troubled with the Senſe of choaking in her Throat: So that, as it is very likely, the morbific matter laid up near the *nervous origine* being rarified and ſtirred, by the fomentation, entred more deeply the heads of the Nerves, appointed for the Lungs, and ſtirred up in their *fibres* and *filaments*, perpetual convulſions: after the like manner, as when the Nervous juice, which waters the *fibres* and tendons of the Muſcles, being made ſharp and degenerate, induces to thoſe parts continual leapings and contractions: hence, when a Convulſion or Spaſm was ſtop'd, in ſome branches of the diſtempered Nerves, ſo as ſhe could not cough, preſently the Convulſive motion, running into other branches of the ſame neighbour Nerve, ſtirred up that choaking in the Throat. I will here propoſe another example of a Convulſion, ariſing from the extremities of the Nerves being affected.

A Noble Matron, of fifty years of Age, after her Courſes had left her for about half a year, began to complain, firſt in a pricking pain of her left Pap; then afterwards, that Diſtemper leaving her, ſhe was ill about her Ventricle, for there aroſe an hard, and as it were a ſchirrous tumour, with a ſad pain; upon this came an inflation of the ſtomach, with difficulty of reſpiration, a nauſeouſneſs, and frequent Vomiting: Then *2. Obſervation.*

Then the diſeaſe encreaſing, with a more ſharp pain running about here and there, ſhe fell into Convulſive Diſtempers of the Ventricle: to wit, in that place, ſhe was almoſt continually troubled with Convulſions variouſly running about, juſt as if her ventricle had been torn to pieces: Beſides a conſtant perturbation of mind, with thirſt, and watchings, and a frequent *deliquium* of ſpirits, as if ſhe had been juſt dying, exerciſing this ſick Lady: All which ſymptoms, ſhe plainly perceiv'd to ariſe from that Tumour in her ventricle: They ſaw that all vomitory, cathartical, antiſcorbutical, and hyſterical Medicines, did her no good, but were rather hurtful and troubleſome; ſhe received ſome benefit, by the taking away of blood by Leeches, and by the uſe of Aſſes Milk, and afterwards ſhe was much eaſed by the drinking of Spaw waters.

The reaſon of it.

The aforeſaid ſymptoms, which commonly are aſcribed to the hyſterical paſſion, and the vapours from the Womb here plainly appear, to have proceeded from a Tumour, ariſing about the bottom of the Ventricle: for that the blood of this Lady being very hot and melancholick, when it could be no more purged by her Courſes flowing from her, it laid up its recrements, and aduſt ſæculencies, at firſt in her Breaſt, and then from a new beginning in the Membranes of her Stomach: From the tumor there made, ſharp and Heterogeneous Particles falling down perpetually, entred the *fibres* and nerves planted round about; which cleaving continually to the ſpirits dwelling in, and flowing into thoſe parts, excited them to frequent exploſions, and ſo made Convulſive diſtempers in all the neighbouring parts: But that ſometimes the Convulſive motions were more light in that place; hence it appears, that the whole nervous ſtock, and the head it ſelf (as is wont to be in greater Convulſions) had not as yet been touched with the ſame diſtemper: But the diſorder of ſpirits ariſing about the parts affected, and from thence transfer'd by a ſmaller undulation or waving to the head, and ſo only lightly diſturbing the ſpirits inhabiting it, induced watchings, with a great heat, and perturbation of the phantaſie. What we have hitherto diſcourſed of Convulſions from the morbific cauſe ſetling upon either end of the nervous ſyſtem, will more clearly appear, when we ſhall hereafter treat particularly of the chief kinds of Convulſions, *viz.* the Hyſterical, hypochondriacal, and other paſſions: In the mean time, there will be no need to add a Curatory method, for this *Hypotheſis* of Convulſions, ariſing by reaſon of the extremities of the Nerves being affected, becauſe the ways of curing may be better accommodated to the Paſſions of this kind, hereafter particularly to be ſpoken of: But for the preſent, it behoves us, to proceed to the unfolding of the Convulſive paſſions, whoſe cauſe, or morbifick matter, ſeems to ſubſiſt within the nervous foldings.

That the nervous foldings is the ſeat of Convulſive matter.

We have largely enough, in another place, diſcourſed of the nervous foldings, and in their deſcription and uſe we have ſhown, that 'tis very likely, the more grievous fits of Convulſive motions, beginning oftentimes within theſe parts, are from thence propagated on every ſide, into the neighbouring parts, and not ſeldom to a great diſtance: at leaſt, that it ſeems much more probable, that the Heterogeneous and exploſive particles, after they have overcome the tract of the head, and its medullary *appendix*, and being more deeply ſlidden into the Channels of the Nerves, and their paſſages, together with the juice watering them, do ſpread their ſtores within the nervous foldings, as it were in Croſs-ſtreets, and by-paths, and there ſometimes make their ſtations, until at length, being more plentifully heaped up, they as it were with collected forces, produce the more cruel Convulſive diſtempers: This I ſay, appears to be much more probable than (what is commonly ſaid) to ſuppoſe them vapours, ariſing from the Womb, Spleen, Ventricle, or any other inward, in which all the fault is eaſily thrown: For within theſe foldings there are ſpaces large enough for morbific mines, that the matter may be there at leaſure laid up, and remain, till it be gathered to a fulneſs: But then, becauſe we believe, that great plenty of ſpirits lodg there, more than in any other little Cells the heterogeneous *Copula* growing to them, lays as it were tinder for more grievous exploſions, ſo that the ſpirits being exploſed within theſe bodies, do not only inflate, and dilate them, but elevate and lift them up from their place, (even as a houſe blown up with Gun-powder;) wherefore the parts lying over them, are ſuddenly lifted up into a tumor, and looſe, are drawn violently hither and thither. That after this manner, the more cruel fits of Convulſions, about the *Præcordia* and *Viſcera*, are very often ſtirred up, I have found to be true, beſides the Arguments taken from reaſon, not long ſince by my own ſight: For when I opened the dead body of a Gentlewoman who had been exceedingly troubled with (as they ſay) the Mother fits, or hyſterical Diſtempers, I found the Womb wholly faultleſs, but the Nerves near the foldings of the *Meſentery*, (as it ſeem'd) only to be lifted up, and elevated into a bulk, and the Membranes of that inward, appeared torn, and looſned one from another, as being on every ſide tumid and looſe, as it were blown up into little bubbles or bladders.

Indeed

Indeed there are more conſiderations of ſolid reaſons, whereby we are induced to believe, that the paſſions called hyſterical, do moſt often ariſe from the convulſive matter heaped up within the *Meſenterick* enfoldings, and by turns exploſed: which ſhall be more clearly manifeſted, where we treat eſpecially of thoſe diſeaſes. But, neither is it leſs probable, that the Collick-pains, do very often proceed from a more ſharp and irritative matter, contained in the ſame enfoldings. Beſides, as often as the convulſive fits ſeem to begin from the ſpleen or ventricle: by reaſon the beginnings of which are inflations, and very great diſturbances of thoſe parrs, it is likely, that the neſt of the convulſive matter, was hid within the nervous enfoldings, belonging to the ſpleen or ventricle: Alſo this kind of matter ſeems to excite within the Cardiac foldings moſt heavy tremblings, and paſſions of the heart; and within the pneumonic or cervical, (of thoſe belonging to the Lungs and Throat) enfoldings, moſt terrible fits of the Aſthma. In our Treatiſe of the Nerves, we have related a notable caſe, of a worthy Gentlewoman, to whom a ſerous matter, wonted to diſtill from the forepart of her head through her left noſtril, fell behind her ear: where when the moſt cruel pain did infeſt her, Convulſions alſo, and admirable contractions followed: whereby the jointing or compaction, now of the brain, and the whole head ſeemed to be pulled downward, now the throat, *præcordia* and *Viſcera* upwards: which kind of Convulſions vexing the parts ſo oppoſite, and at ſuch diſtance by turns, when they did proceed from one and the ſame ſeat of the diſeaſe, planted in the midſt, it will be obvious to conceive, that the grieved place, as the origine of either convulſive affection was the ganglioform enfoldings, planted near the *Parotidæ* or the two chief *Arteries* of the throat: into which the Nerves both of the wandring pair deſcending from the head are entred, and out of which the ſhoots do ſtretch themſelves, into the muſcles of the throat and branches into the *præcordia*, and *viſcera*. Further from the ſame cauſe, to wit, the convulſive matter heaped up, and by turns exploſed, within the ganglioform enfoldings, we think, (and not undeſervedly) that ſenſe of choaking in the Throat, ſo often excited in the convulſive fits, did proceed. But there will be a more fit place, to ſpeak of this, when we ſhall particularly handle the convulſive diſeaſes and ſymptoms. We ſhall now endeavour to ſearch into what remains, of the laſt kind of Convulſions, of which we made mention above, to wit, which relies on the nervous Liquor being infected thorow its whole maſs, with heterogeneous and exploſive particles, and for that reaſon, irritating the whole proceſſes of the Nerves, and the nervous bodies, into univerſal Spaſms, or Convulſions; and thoſe either continual, or intermitting.

CHAPTER VII.

Of Convulſive Motions, ariſing from the Liquor watering the nervous Bodies, and irritating their whole proceſſes into Convulſions.

THat Convulſive diſtempers do ſometimes wander thorow the whole nervous ſtock, and infeſt now theſe parts, now thoſe, now many together, is ſo noted, and obvious almoſt to daily experience, that nothing can be more: we may therefore take notice in theſe, that the tendons of the Muſcles do every where leap up, and are drawn together with ſpaſms; in others, ſome exterior members are bended or ſtretched forth, with various flections, and contortions, here and there, after divers manners; we have ſeen ſome forced by the unbridled and untamed force of the ſpirits, as if ſtruck with madneſs to run or leap about, or ſtrongly to ſmite, with their feet, or fiſts, the earth or any objects: which if they ſhould not do, forthwith they would fall into ſwooning fits, and horrid Eclipſe of ſpirits. It would be too tedious, to enumerate all the caſes of univerſal Convulſions, wandring thorow the whole nervous ſtock: But the ſymptoms of this kind, tho they are vorious and manifold, may be reduced nevertheleſs to three chief heads; to wit, foraſmuch as they depend chiefly upon three kinds of cauſes; for indeed in theſe wandring Convulſions we ought to ſuppoſe the whole nervous Liquor to be vitiated, and the animal ſpirits, flowing every where in the ſame to be adulterated, and for that reaſon, to be almoſt perpetually exploded: Take notice then, that this kind of infection is moſt commonly impreſſed on the nervous

Chiefly three kinds of cauſes of univerſal Convulſions.

juice, and the spirits every where flowing in it, by one of these three ways, *viz.* 1st. By Poysons or Witchcraft. 2dly, From malignant or ill-cured fevers, in which the morbific matter is poured forth on the Brain, or nervous stock. Or 3dly, When the nervous Liquor, by a long tract of time, by reason of the scorbutic, or otherwise vitious distemper, doth degenerate from its due constitution into sour, or acid, or any otherwise præternatural and Convulsive Liquor: we will here consider of each of the aforesaid cases, and first of all, of the fits of Convulsion, which are produced by poysons or Sorceries.

From poysons and sorceries.

First therefore, it is somewhere shown by us, that some poysons do act rather on the nervous Liquor, than on the blood, which depraving it most strongly, induce Convulsive distempers: And it appears clearly, from the eating of *Hemlock*, the *laughing Parsly*, *man-drakes*, the furious *nightshade*, *wild Parsnips*, and other hurtful herbs, how soon after horrid Contractions of the *Ventricle*, *numbness*, *delirium*, Convulsions, twitches of the *tendons*, in the whole body, were wont to follow. Besides, those kind of Convulsions follow upon the biting of a mad Dog, and other venomous beasts, where the virulent infection, being received by the nervous juice, and lurking a long while in it, at last puts it self forth, and infects and poysons the whole mass of Liquor, in which it was involved, with its ferment. But what doth yet more illustrate it, are the admirable Symptoms, the truly painful Convulsions, and unweariable dancing, which Authors have related to follow upon the biting of the *Tarantula*; and indeed, might seem fabulous, unless that the truth of the Thing were asserted by many men of good Credit, both ancient and modern: For besides *Mathiolus* and *Epiphanius*, *Ferdinand*, *Gassendus*, and *Kirchir*, add, that themselves were eye-witnesses of this distemper: yea it is said, 'tis a known thing in *Apulia*, and found almost by daily experience, that in that part of the Country, there are *Phalangii*, or a certain kind of Spider, which is called *Tarantula*, from *Tarenta* an ancient City of *Apulia*. This little Animal, being very frequent in the summer, often bites the heedless Countryman, and infects him with its Venomous Stroke, from whence presently succeed a pain in the hurt part, with a Tumor and itching, and by and by in various parts of the body, a numbness, and trembling, also Convulsions, and loosenings of the members, and other Convulsive Symptoms, with a great loss of strength; as may be collected from *Mathiolus*, *Ferdinand*, and others, relating the wonderful effects of this Disease. But truly, what these Authors say concerning the cure of this Distemper, and is practised commonly thorow the whole country, is worthy of great admiration: for these stung with a *Tarantula*, as very sick as they are, as soon as they hear musical Instruments, presently they are eased of their pains, and leaping into the middle of the room they begin to dance, and jump about, and so continue it a long while, as if they were well, and ailed nothing; but if it happen, that the Fiddlers leave off never so little a while, they straitways fall to the ground, and return to their former pains, unless by the incessant musick, they dance, and leap till the poyson be wholly shaken off: For this end therefore, Musitianers are hired, and are changed by turns, that without intermission of the noise, those who are bitten, may dance so long till they are quite cured. Thus saith *Mathiolus*; To which *Ferdinand* adds, that poor people do expend almost all their substance, in these fidlers and musitians, who wander up and down all that Province; and by playing to these *Tarantulasized* people, make much benefit: they dance or leap about in the villages and publick streets, and fields, some one day, some one week, and others more. To these Authors, the most learned men, *Gassendus* and *Kircherus* agree, both of which have related it from their own Observation, that they have known such affected; and they assert, that they are not affected or excited indifferently with any musick, but with certain kinds of Tune, and that they dance to some measures before others.

From poysons of the rank of vegitables.

From a mad Dog.

The reason of the symptoms of those bitten by a Tarantula.

Let us inquire a little further into the reasons of the aforesaid Accidents, if we may follow our conjecture, in this first place, 'tis without doubt, that a certain venomous infection is fixed on the humane body, from the bite of this little creature, which tho it being less infestous to the blood and vital spirit, as soon as ever it passes from it into the nervous Liquor, it presently unfolds it self thorow its whole Mass like leaven, and infects the animal spirits, flowing every where in it; so that indeed, they being drawn one from another, and here and there inordinately moved, induce convulsive distempers, which are accompanied now with the contractures, now with the languishing, and resolutions or loosening of the containing parts.

In what the reason of the Musicks allaying the symptoms consists.

But why the painful Convulsions, which are raised by the bite of the *Tarantula*, being presently allayed by musick, are wont to turn into dancing, does not so plainly appear. That some affirm this little animal (for that by the testimony of *Aristotle* it should be most wise) to be delighted with musick, and for that reason, its venom being in-

impreſſed on man, by fermenting the humors, to induce the like love of muſick: I ſay, this conjecture will not ſatisfie a mind deſirous of Truth, becauſe, that ſuppoſes a muſick loving nature in the ſpider, and the ſame to be communicated to man, by a *metaſtaſis*, or as it were a certain *metempſycoſis*, or tranſmigration of ſoul, both which are taken upon truſt, and little ſatisfactory; but it may be rather ſaid, that the venom inflicted on the nervous liquor, by the bite of the *Tarantula*, is too gentle to be able to extinguiſh wholly the Animal ſpirits, or to diſſipate them very much aſunder, and to compel them into more cruel exploſions, but only to put them to flight, and to incite thoſe flying here and there, into lighter, and ſomewhat painful Convulſions; and that the Muſick with its flattering ſweetneſs, doth congregate together, and mutually aſſociate with eaſe the ſpirits ſo diſſipated; wherefore, whenas the ſame ſpirits, by reaſon of the Infection ſticking to them, are apt to involuntary and Convulſive motions, the melody diſpoſes them, delighted together, and directs them to ſuch Convulſions, that entring the bodies of the nerves, by a certain Courſe and Order, they are carried as it were in certain preſcribed limits and compaſſes, until at length the particles of the venom, being quite evaporated, and the fury and rage of the ſpirits being worn out, they wholly ſhake off that madneſs. For truly, muſick doth eaſily carry men ſound and ſober, whether they will or no, or thinking of another thing, into actions anſwerable to the ſound of the harmony; that preſently the ſtanders by, at the firſt ſtriking up of the fiddle, begin to move their hands and feet, and can ſcarce, nay are not able to contain themſelves from dancing: Let none therefore wonder, that in men bitten by the *Tarantula*, when the animal ſpirits being moved, as it were with goads, they are compelled to leap forth, and wander about hither and thither willingly, if they are excited to dancing and compoſed meaſures, at the ſtroke of an harp, ſo that as in theſe diſtempers, the ſpirit of the muſick, as it were inchanting the outragious ſpirits, and in ſome meaſure governing, and changing their convulſive motions, ſerves inſtead of an Antidote: for that the animal ſpirits, being very much, and for a long while exerciſed, after this manner, wholly ſhake off the Elaſtic *Copula*, contracted by the poyſon, or otherwiſe; and they being very much wearied, at length reſt from that madneſs, or its incitation.

A deſcription of the dance of St. Vitus.

That which is called the *Dance of* St. *Vitus*, is an evil akin to this, concerning which *George Horſtius* relates, that he had ſpoken with ſome women, who for ſome years, viſiting the ſhrine of St. *Vitus*, which is in the borders of *Ulme*, did there exerciſe themſelves even night and day, with dancing and diſcompoſure of mind, till they fell down like people intranced: by which means, they ſeemed to be reſtored to themſelves, that they felt little or nothing for a whole year, till about the time of *May* following, when by the inquietude of their members, they ſaid, they were ſo far tormented, that they were forced to go for their health ſake yearly to the aforeſaid place, about the feaſt of St. *Vitus*. *Horſt. Epiſ. Med. Sect. 7. de admirandis Convulſionibus.*

The reaſon of it.

Indeed it is a uſual thing (as I have obſerved) both for men and women, to be ſometimes tormented with this inquietude of their members, and as it were with a fury or madneſs, that they have been forced to walk, till they were tired, as alſo to dance, leap, and run about, here and there, that by this means they might ſhun the grievous trouble, and ſometimes faintings away, which were about to invade them: The reaſon of which ſeems to be, that the animal ſpirits, foraſmuch as they being incited by an heterogeneous *Copula*, in the whole nervous kind, become fierce, and altogether unbridled, which to exerciſe and tire out, there is need, both that they themſelves may be tamed, and that the exploſive *Copula* may be ſhaken off.

Univerſal Convulſions from Witchcraft.

That Convulſive diſtempers are ſometimes excited by witchcraft, is both commonly believed and uſually affirmed by many Authors worthy of Credit: and indeed, as we do grant, that very oftentimes moſt admirable paſſions ate produced in the humane body by the deluſions of the Devil, forasmuch as he, to cauſe wonders, by which he might rule, by the ſubtlety of working, inſinuates to the ſenſitive ſoul, or the conſtitution of the animal ſpirits, heterogeneous Atoms or little Bodies, and ſo adds now ſpurs or pricking forward, and now caſts chains on its functions, and now carries them to miſchief: alſo by ſome means he enters himſelf into the humane body, and as it were another more mighty ſoul, is ſtretched thorow it, actuates all the parts and members, inſpires them with an unwonted force, and governs them at his pleaſure; and incites to the perpetrating of moſt cruel and ſupernarural wickedneſſes: yet all kind of convulſions, which beſides the common manner of this diſeaſe, appear prodigious, ought not preſently to be attributed to the inchantments of Witches, nor is the Devil preſently or always to be brought upon the ſtage. For indeed as often as a child, or relation of ſome man of the richer ſort is by chance taken with moſt cruel and unuſual Convulſions, for the moſt part it falls out, that by and by the next old Woman

Which are commonly but calſly ſo thought.

is accuſed of Witchcraft, ſhe is made guilty, and very hardly, or not at all, the wretch eſcapes the flames, or an halter; when in the mean time, the Diſeaſe proceeding from cauſes meerly natural, may be eaſily cured, by no other Exorciſm, than Remedies uſually preſcribed againſt Convulſive Diſeaſes: In truth, the animal ſpirits being indued with a more cruel exploſive *Copula*, and being ſtrucken by it all of a heap together, obtain ſo much ſtrength and vigour, beyond their proper and wonted power, as the flame of Gun-powder has above the burning of the common flame; ſo that thoſe who obnoxious to this Diſeaſe, out of the fit may be govern'd, lifted up, and moved at pleaſure, with the light help of one man; when the ſame is upon them, make nothing of the utmoſt endeavours and force of at leaſt four of the ſtrongeſt men: But if in the caſe of any one that is ſick, there ariſe a ſuſpition of Witchcraft, or Faſcination, there are chiefly two kinds of motions that are wont to create and cheriſh this opinion, *viz.* 1. If the Patient doth perform the contortions or geſticulations of his members, or of his whole body, after that manner, which no ſound man, nor mimick, or any tumbler can imitate. Then, Secondly, If ſuch ſtrength be ſhown, that ſurpaſſes all human force; to which, if the avoiding of monſtrous things happen, as when bundles, as *Henry van Heers* relates, are caſt forth by Vomit; or a live Eel, as *Cornelius Gamma* tells, voided by Stool, without doubt it may be believed that the Devil has, and doth perform his parts in this Tragedy.

The reaſon of them.

Which argue witchcraft.

It were eaſie to heap together very many, and indeed admirable Hiſtories of perſons of every Age and Sex, affected after a ſtupendious, and as it were ſupernatural manner, with the manifeſt ſuſpition of Witchcraft: for ſuch are every where extant among Authors, both Phyſicians', and Philoſophers; and becauſe vulgar rumor noiſes about Diſeaſes cauſed by Witchcraft, to happen often in almoſt every Country: but becauſe theſe kind of caſes are full of Impoſture, or always increaſed by the fictious lies of the relators, to create admiration (and for that they rarely fall under the medical cure) I will here purpoſely omit them: what remains is, That I proceed to unfold the next kind of univerſal Convulſions, to wit, which comes upon malignant, or otherwiſe irregular or ill-cured Fevers.

CHAPTER VIII.

Of Univerſal Convulſions, which are wont to be excited in Malignant, ill-cured, and ſome irregular Fevers.

Univerſal Convulſions hapning in Fevers.

THat Convulſions ſometimes happen to perſons ſick of Fevers, almoſt every ordinary body underſtands, and from thence takes a remarkable Prognoſtication of death, or peril: For in malignant Fevers, alſo ſometimes in the ordinary ill-handled, as the *Virtego*, or *Delirium*, ariſe from the morbific matter being laid up in the Brain, from the Blood; ſo from the ſame, being ſlidden down into the Nervous ſtock, contractures and twitches of the Muſcles and Tendons; alſo ſudden ſhakings of the Members and Limbs; and ſometimes moſt horrid ſtifneſſes in the whole Body ſucceed: The reaſon of which kind of ſymptoms ſeems to conſiſt in this, that the Liquor watering the Nervous parts, abounds every where with heterogeneous Particles irritating the ſpirits: for by that means the ſpirits inhabiting and influencing, being diſturbed in their juſt influence and emanation, are incited into continual exploſions, as it were a crackling noiſe, not much unlike, as when the flame of a Lamp being imbued with droſſy and ſalted Oil, aſcends with a noiſe and ſparkling: which kind of Convulſive Diſtempers, for the moſt part, happen about the height of Fevers, when the morbific matter being firſt laid up in the blood, is from thence transfer'd to the brain; and that being paſs'd thorow, and alſo infected, it is carried into the ſyſtem of the Nerves, and from thence ſtirs up Convulſive paſſions, with or without a *Delirium*.

The reaſon of the ſymptoms.

But indeed, it is ſometimes obſerv'd, That beſides theſe kind of Convulſive Diſtempers, coming upon Fevers, and ſecondarily excited; in a malignant conſtitution of the Air, alſo from the Breath of a Peſtilent Contagion, the Nervous Liquor hath been infected before the blood, or elſe apart from it; and therefore a *Delirium*, or Convulſions, have gone before a Feverish Diſtemper. Further, I have often obſerved, That ſome irregular Fevers have aroſe, in which the blood has been hardly ſeen to boil up, or grow hot above meaſure, but the beginnings of this ſlow and very dangerous

gerous Fever, were laid chiefly in the nervous humour; which being by degrees brought to maturity, did induce Convulsive Distempers, with a *Delirium*, or madness, and other wastings or exorbitances of the Animal Spirits. For the sick never complained of heat, or thirst, being soon made feeble, and as it were strengthless, they were presently obnoxious to frequent giddiness, also to tremblings of the Limbs, and as it were leapings forth; besides, to twitches or jumpings of the Muscles and Tendons, and to contractures, and pains wandring about, here and there. This kind of sickness, by some Physicians, because it seem'd to consist in the solid parts, rather than in the blood, is called a *malignant hectick Fever*; when indeed, the same being fixed chiefly in the nervous humour, may be better called, the *Convulsive nervous Pestilence.*

A description of a convulsive disease of Hassia, sometimes epidemical.

There is mention made by *Gregory Horstius*, of a *Convulsive* and *malignant Disease*, which was sometime past *Epidemical*, in *Hassia*, *Westphalia*, and the neighbouring Countries: they being taken therewith, without a Feverish heat, immoderate effervescency of blood, whilst they were imployed about their familiar occasions, hardly perceiving themselves to be sick, were wont to have about their hands or feet, and sometimes in both, a sense of tingling, with a numness running up and down: then, by and by, their fingers, together with their Arms and Thighs, were now strictly drawn together, now most strongly stretched forth, as if they were frozen. Those kind of contractions, and extentions, rendred themselves by turns, and then changed places, that now the distemper resided in one part, then presently in another: But (as it often hapned) if the Disease at once invaded the whole Brain, universal Convulsions, and oftentimes epileptical fits, infested the sick: besides, those labouring with it, were obnoxious at some turns to a *Delirium*, *Madness*, and sometimes a *Lethargie:* This sickness continued a long time, without any *Crisis*, or sound solution, and could scarcely be so perfectly cured, but that the disposition of the Brain, and nervous parts remained evil all their life after.

The reason of the symptoms.

As to the reasons of this Disease, and symptoms, it is obvious enough, that the same depends altogether upon the vice, and notable depravation of the nervous juice. That pricking, or tingling, for the most part, at the first coming of the disease, was procured for this reason: because that Liquor, beginning to be poysoned, and loosned in its mixtion, by the malignant infection, presently it oppressed the animal spirits, abounding therein, and inhibited them from their wonted and free expansion; wherefore, they being half overwhelmed, and constrained to creep, as it were, among Briers, or things that catch'd hold of them, or held them back, they excited the sense, as it were of tinglings, running about: but then, because this Disease growing worse, the nervous Liquor was yet more perverted in its *Crisis* or disposition; the Heterogeneous Particles, which were brought together in it, cleaving to the spirits, caused them to be moved hither and thither, and to be unduly exploded; for which reason, the contractions and horrid distentions in the members, and the tumults and great inordinations in the head, were raised up. But that in this Fever of the Nerves a solution or difficult *Crisis*, or none at all hapned, the reason was, because the nervous juice being slow, and as it were mucilaginous, and therefore heavy in its motion, was not defæcated or cleared, as the blood, by a critical effervescency, nor easily conceived, that kind of fermentation by which the pure might be separated from the impure.

Indeed I have known a sickness, much like to this example, to be often excited in our Country, and to invade whole Families, especially Children, and the younger People. Some years since, a popular or childish Fever, very much infesting the Brain and Nervous stock, exceedingly spread in this Country, yea almost thorow all *England:* The History of which Disease, being described in that time, in which it raged, *viz.* in the year 1661. I think it worth our pains to insert, in this place of our Convulsive *Pathology:* For from hence, it may appear, by what means, and from what causes, the Convulsive symptoms, which come upon any Fevers, are wont to be excited.

A Deſcription of an Epidemical Fever chiefly infeſtous to the Brain and Nervous ſtock, ſpreading in the year 1661.

The Hoſtory of an Epidemical Fever raging in the year 1661.

IN this Country, before the laſt Summer, *viz.* 1661. we had been free for above two years, from any popular Diſeaſe, unleſs ſuch only as uſually come in ſome places; but then, before the Summer Solſtice, the *ſmall-Pox* (a diſtemper here rarely Epidemical) being riſe in many places, raged very much: After that Summer, which was extreamly hot and dry, an Autumn moiſter than uſual followed: and after which, a moſt mild Winter, almoſt without any cold: in all which ſpace, the Earth was hardly covered with Snow, or was ever hard frozen, above three or four days; ſo that within a few weeks, after the Winter Solſtice, the Trees began to bud, and the vernal Plants to break forth from the boſom of the Earth, and to flower, and alſo the birds to build neſts: to this mild ſeaſon, not eventilated at the beginning of the ſpring, by the nitrous little bodies that were wont to be blown from the North, a filthineſs of ſhowers, and almoſt continual wet ſucceeded. After the vernal *æquinox*, a certain irregular, and unaccuſtomed Fever, ſeiſed upon ſome, here and there, which within a month became ſo Epidemical, that in many places it began to be called the *New Diſeaſe*; Raging chiefly among Children, and Youths; it was wont to afflict them with a long, and as it were a chronical ſickneſs: yea ſometimes, old men, and men of middle Age, though rarely, were ſeiſed by it, and thoſe indeed, it did ſooner, and more certainly kill. The Diſtemper at firſt invading any one, did creep on them ſo ſilently, that the beginnings of the ſickneſs were ſcarce perceived: for ariſing without immoderate heat, or more ſharp thirſt, it induced in the whole body a great debility, with a languiſhing of the ſpirits, and a torpitude or numbneſs of the function; The Stomack was ready to loath any victuals, and to be grieved at any thing put into it, and yet not eaſie to vomit. The ſick were unfit for any motion, and only lov'd to be idle, or to lie down upon the Bed: within a ſhort time, alſo ſometime at the firſt coming of the Diſeaſe, they complained of a heavy *vertigo*, a tingling of the ears, and often of a great tumult and perturbation of the brain. Which kind of ſymptoms were often eſteemed, as it were the peculiar ſign of the approach of this Diſeaſe, if in ſome thoſe had been wanting, or hapned to be more remiſs, inſtead of the head being affected after that manner, the Diſeaſe took more deep root in the Breaſt, with an excited Cough, as ſhall be told by and by. But whilſt the Brain, and the Nervous *Appendix*, being after this manner affected, the animal ſpirits, preſently from the beginning of the ſickneſs, were benummed, a ſlow, and as it were Hectick Fever, was inkindled throughout: but yet the efferveſcency of the blood, which was hardly continual, but flitting and uncertain, was according to the diſpoſition of the blood it ſelf, in ſome more intenſe, in others more remiſs; and therefore, thirſt, the white ſcurf of the Tongue, and other ſymptoms, which accompany a feveriſh diſtemper, did more or leſs infeſt them: ſweating did not willingly follow; nor could it eaſily, or by a light thing be cauſed by Art: yea, neither this, nor any other evacuation, as it were critical, at any time ſucceeding, did ſuddenly help this Diſeaſe; but it perſiſting for many weeks, and ſometimes months, reduced the ſick to the higheſt *Atrophie*, or waſting of all parts, and often infected them with an incurable Conſumption.

Its procatartick or more remote cauſe.

The Symptoms.

About the increaſe of the Diſeaſe, which hapned in moſt within eight days, if the Diſtemper (as it was often wont) did ſettle chiefly in the head, and nervous ſyſtem, moſt grievous ſymptoms, in their Dominions, *viz.* a plain Phrenſie, or deep Stupidity, or Inſenſibility did moleſt them. For I often obſerved, in many Children, and not ſeldom in Women, after ſeven or eight days from their falling ſick, that their knowledg and Speech failed them, and ſo the ſick have lain, for a long while, yea, ſometimes for the ſpace of a whole month, without any taking notice of the by-ſtanders, and with an involuntary flux of their excrements; but if they continued in ſome ſort the uſe of Judgment and Reaſon, they laboured with a frequent *Delirium*, and conſtantly with abſurd and incongruous *Chymera's* in their ſleep. But in men, and others of a hotter temperament, from the morbific matter, inſtead of a *Criſis* being tranſlated to the brain, a fury, or dangerous, and oftentimes deadly Phrenſie did ſucceed. But if neither ſtupidity, nor great diſtraction did fall upon them, ſwimmings in the head, Convulſive motions, with Convulſions of the members, leapings up of the *tendons*, did grievouſly infeſt them. In almoſt all the ſick, the belly was for the moſt part looſe, caſting forth plentifully now yellow, now thin and ſerous excrement, with a great ſtink: it was rarely that vomiting fell upon any one: The urine in the whole proceſs of the Diſeaſe,

Diſeaſe, (unleſs when the morbific matter being carried more plentifully into the Brain, did threaten a Phrenſie) was highly red, ſo that ſome, by reaſon of the deep colour of the water, judg'd this Fever to have been plainly Scorbutick: which notwithſtanding appeared to be otherwiſe, becauſe *antiſcorbutic* Remedies, (of which indeed many, and almoſt of every kind were tried) were little or nothing beneficial. It was moſt of all to be admired, how ſoon after the beginning of this Diſeaſe, the fleſh of the ſick conſumed, and they reduced to the leanneſs of a *Sceleton*, when in the mean time there was no great heat that might by degrees conſume the ſolid parts, nor any violent evacuation, which might greatly take them down.

Beſides theſe evils moleſting the region of the head, a diſtemper no leſs dangerous oftentimes fell upon the breaſt. For in ſome, tho not in all, a Cough very troubleſome, with abundance of ſpittle, and thick, was excited: this hapned in ſome about the declination of the Diſeaſe, to wit, whilſt the confines of the brain were ſerene, as it were the clouds ſent from thence to the Thorax, a great *Catarrh* ſuddenly rained down upon the Lungs. But in others, who eſpecially had little infection of the Diſeaſe in the head, preſently after the beginning of the Fever, a cruel Cough, and a ſtinking ſpitting, with a conſumptive diſpoſition, grew upon them, and ſuddenly, and unthought of, precipitated the ſick into a *Pthiſis:* from which, nevertheleſs, they recovered, by the timely uſe of Remedies, often beyond hope. It was obſerv'd in ſome, That after a long eclipſe of the ſenſitive facultie, and oppreſſion of the brain, from the morbific matter, at length tumors did follow, in the glandula's, near the hinder part of the neck, out of which, being hardly ripened and broke, a thin and ſtinking ichor or matter ran for a long time, and brought help. I have alſo ſeen watery puſtles excited in other parts of the body, which paſs'd into hollow ulcers, and hardly curable: ſometimes little ſpots, and *petechiales*, appeared here and there: yet I never heard that any more broad or blew, of theſe kind, were ſeen in the ſick. Notwithſtanding, tho this Fever was not remarkable for very many malignant ſpots, yet it was not free from Contagion. For that in the ſame Family, it invaded almoſt all the Children and Youths ſucceſſively, yea not rarely thoſe of more ripe years, and at mens eſtate, who looking to the ſick, were familiarly converſant in their Chambers, or about their beds, were infected with the ſame infection: But indeed, there was not ſo much cauſe of ſuſpition, that for it the friends of the ſick ſhould be wholly interdicted from commerce with, or viſiting of them.

Altho the courſe of this Diſeaſe (unleſs when it intimately ſetled in the brain) did appear ſo gentle, and continued without any horrid ſymptom; yet its cure being always difficult, ſucceeded not under a long time: For the ſick rarely grew well within three or four weeks, yea for the moſt part ſcarce in ſo many months. If this Diſeaſe fell upon men of a broken Age, or ſtrength, eſpecially thoſe who were before obnoxious to *cephalic* diſtempers, as the *Lethargie*, *Appoplexie*, or Convulſion, it oftentimes kill'd them in a ſhort ſpace: but if there was any hope of recovering, it could be but ſlowly procured, (all Remedies whatſoever ſcarce bringing any ſenſible help) ſo that the ſick did no ſooner come out of the ſphere of this Diſeaſe, than they fell into the confines of a Conſumption.

If the formal reaſon, and courſes of this aforeſaid ſickneſs be demanded, it here eaſily appears, the watering liquor of the brain and nervous ſtock, for the moſt part both together, with the blood, to be in fault; and the immediate cauſe, eſpecially of the troubleſome ſymptoms, to wit, foraſmuch as this water, preſently after the firſt aſſault of the Diſeaſe, was grown more poor than uſual, and as it were lifeleſs; therefore a languiſhing, and enervation, with a *ſpontaneous* wearineſs and impotency to motion, hapned in the whole body, and with a ſudden waſting of the body in the ſick. Further, foraſmuch as the ſame Liquor was ſtuffed with heterogeneous Particles, *viz.* partly narcotick, partly exploſive; therefore a numbneſs, a ſenſe of pricking, leapings up of the tendons and muſcles, and contractures, alſo the *Virtego*, giddineſs, and other more grievous Cephalick diſtempers did ariſe. Moreover, foraſmuch as by reaſon of the evil of the nervous juice, being not quickly or hardly to be mended, the cure or healing of the Diſeaſe became ſo hard and lingring. But for that the fault of this *Latex*, neceſſarily depended on the diſcraſie or evil diſpoſition of the blood, alſo of the depraved conſtitution of the brain, what their morbid diſpoſitions were, and by what means they brought forth the beginning or tinder of the ſymptom of the Fever but now deſcribed, let us now ſee. *The reaſon of them.*

As to the former, it ſeems, that at this ſeaſon, by reaſon of the hot and humi'd conſtitution of the year, and no blaſt from the north (the little bodies of which imbue the blood and juices of our body, as it were with a nitrous ſeaſoning, and by agitating them, defend them againſt putrefaction) the blood in moſt men, and chiefly in Children,

dren, Youths, and Women, became like ſtanding-water, that ſo contracts a ſetling very impure, ſtuft with heterogeneous particles, and turning to a clammineſs, and watriſhneſs; in which, the more pure ſpirit and ſulphur, being ſomewhat depreſs'd, the watery particles, being carried forth with the impure ſalt and ſulphur, were too much exalted. Wherefore the blood, both by reaſon of its *Criſis* or conſtitution being vitiated; alſo by reaſon of heterogeneous particles being heaped up more plentifully in its boſom, was made more fit, either of its own accord, or occaſionally, or becauſe of the contagion to receive a feveriſh Efferveſcency, ſo that from thence, very many fell at this time into fevers. But the blood growing hot, from the feveriſh taint being received, did not preſently burn with an open flame, but like green wood laid on the fire, with a flame as it were ſuppreſſed, and much incumbred with ſmoke. Wherefore, the morbific matter, being heaped within its maſs, was not wont (as in a regular fever) to be conſumed by the burning, and its reliques at the ſet time to be exterminated by the *Criſis*: but yet, a little after the beginning of the feaver, a great portion of this matter being poured into the head or *Thorax*, or into both at once, and afterwards being continually ſupplied in thoſe parts, it induced either the aforeſaid diſtempers of the brain and nervous ſtock, or cough with a conſumptive diſpoſition, or both together; and for this reaſon, about the beginning of this diſeaſe, when a pulſe quicker than it ought to be, and a high coloured urine, and full of contents, did ſhow the blood to grow hot with a Feveriſh diſtemper, the ſick did not complain of heat, or thirſt, becauſe the blood growing hot, did lay up its impurities and recrements, forthwith into the proviſion of the nervous Liquor, or into the Lungs; wherefore, within theſe receptacles, the Symptoms preſently became worſe; but afterwards the diſeaſe growing on, a ſomewhat ſharp heat, with ſcurfneſs of the tongue, was wont to be troubleſome to ſome: yea, in all, a ſlow, and as it were hectick fever, continued throughout; which neither by ſweat, nor by inſenſible tranſpiration, could be ſo wholly removed, but that it was daily renewed, chiefly after eating, tho never ſo ſmall: which thing truly ſeemed to happen, becauſe the nervous juice being full of the feculencies brought from the blood, did not afterwards receive them in ſo great plenty, but that theſe recrements, together with the nutricious humor, (and for that this was not conſumed by nouriſhing the ſolid particles) remaining within the bloody maſs, cauſed it then to grow feveriſhly hot.

2ly, Beſides this morbid diſpoſition of the blood, contracted from the intemperance of the year, it ſeems, that the brain alſo, from the ſame occaſion, was made prone to the aforeſaid paſſions. For when for a long tract of time, the ſouthern winds did continually blow with a moiſt conſtitution of the air; from thence the paſſages and pores of the brain, being very much looſned and opened, and its connexion too much diſſolved, they gave an eaſie paſſage to ſerous humors, and for all ſorts of heterogeneous particles; wherefore the blood being very feculent and watery, as ſoon as it began to grow hot from the fever, carried its ſerous recrements and filths, preſently thorow the two open doors into the head: for whoſoever he was, who did not complain of his head, being too much ſtuffed with a moiſt air, and numbneſs of ſpirits; on the contrary, his pores being bound together by an intenſe cold, or drier air, all his ſenſes and faculties remained more quick and lively.

Theſe things being thus premiſed, concerning the morbid proviſion of the brain and humors, to wit, of the blood and nervous humor by reaſon of the conſtitution of the year, whereby indeed, very many at that time, fell into a ſlow, uneqnal, and long continuing fever, ſurrounded with *Cephalic* and *Convulſive* ſymptoms, and hardly curable: hence alſo it will be eaſie to unfold the reaſons of the reſt of the ſymptoms and accidents, chiefly to be noted in this diſeaſe.

Why this diſeaſe chiefly invaded children, women, and phlegmatick men.

For firſt of all, that this irregular Fever raged chiefly among Children, young Men, Women, and phlegmatick men, the reaſon was, becauſe in thoſe kind of bodies, the blood was apt to be more wateriſh, and leſs perſpicable, and from thence to gather a ſerous *Colluvies*, or watry humor and heterogeneous feculencies; and alſo, the brain being more humid and weak, eaſily received any recrements of the blood. Wherefore it may be obſerved, that thoſe ſort of perſons, were found more prone to Convulſions, ariſing by reaſon of any other occaſions.

The reaſon of the Atrophie coming upon the fever.

Secondly, the noted *Atrophie* or leaneſs, came ſo ſuddenly upon this fever, becauſe by reaſon of the depravation of the nervous juice, the officies of nouriſhment, depending upon it (which as we have elſewhere ſhown, are highly active) preſently failed. For altho we do not grant, the nervous humor to be only nutricious, but to diſpenſe thorow the Arteries, a matter deſtinated to the nouriſhable parts, prepared in the bloody maſs; yet it may be lawful to think, that the Liquor watering the brain and nervous ſtock, by means of an efficient cauſe, doth conduce very much to alimentation; for this growing

ing turgid with animal ſpirit, actuates and invigorates the nutricious juice, brought to every part by the blood, and admitting it into the paſſages, and moſt intimate receptacles of the body to be nouriſhed, and as it were leading it in, aſſimilates or reſembles it; wherefore, when this houſhold liquor is ſo depraved, that it doth not rightly ſupply the animal ſpirits, requiſite about the work of nutrition, all the members and parts of the ſtomach vitiated in its tone, either ſpues back whatſoever nouriſhment is brought, or cannot receive it to its proper uſe: wherefore truly in this Diſeaſe, the bulk or habit of the body, however fuller or fatter, was more ſooner pulled down, than in a continual Fever, where it might much more evaporate by the intenſe heat, or copious ſweats. The reaſon of which is, becauſe in a burning Fever, altho the blood growing very hot, exhales more plentifully; yet in the mean time, it continually affords ſomething of nouriſhment, which the ſeveral parts helped by the benefit of the nervous juice, eaſily received and aſſimulated; but in this nervous Peſtilence, altho the nutritive matter was ſufficiently provided, yet by the defect of the nouriſhment of the ſpirits, the nouriſhment was altogether inhibited.

Why this Fever was hardly curable.
